"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, JULY 2, 1913. NO. 1.

NOTES AND COMMENTS.

Sir Ronald Ross and the Medical Research Committee. MEDICAL men are as a rule reticent and guarded in their speech. This habit has probably become ingrained in them to some extent because of the progressive nature of their professional work. That which is orthodox to-day is to-morrow abandoned in favour of a better and sounder belief, so that a dogmatic doctor is apt to find himself suddenly pilloried as the teacher of false gospel. Another reason for the timidity of utterance that characterises the great majority of our profession is doubtless the iron grasp of the corporations and various other medical organisations, which treat strong individuality and plainness of speech as an unforgivable sin. Whatever the reasons may be, the fact remains that the plain speaking ring of public criticism is for the most part conspicuous by its absence as regards the internal life and politics of the medical world. It is all the more refreshing to hear someone who has the courage of his opinions, especially when that individual has attained professional eminence. Writing to the *Times* last week, Sir Ronald Ross condenses a scathing criticism on the composition of the Medical Research Committee within the space of eight lines. He writes: "There are some half-dozen living Englishmen who have done great work on the investigation of disease. It is characteristic of English administration that the name of not one of these appears on the committees just appointed to administer the first adequate national fund ever laid down in this country for medical research." Many of our readers will agree with Sir Ronald Ross. It may be remarked generally that the list of names upon which he vents his sarcasm is more notable for its sins of omission than of commission.

Sir Victor Horsley and the R.C.S. A LETTER from Sir Victor Horsley in our correspondence columns gives us a further reminder that the art of speaking out still exists in the medical profession. Perhaps, after all, it may be a developing instead of a disappearing mental characteristic. At any rate, Sir Victor trounces Mr. McKenna on the one hand and the constitution of the Royal College of Surgeons on the other with a vigour and whole-heartedness that would satisfy a high Hibernian standard. As pointed out in these columns in our last issue, we agree with him that the secret appeal of the Home Secretary to the President of the Royal College of Surgeons was unprecedented and unwarrantable. The only conceivable object must have been to ask the College to punish certain members of the College for an alleged attack (which is categorically denied by Sir Victor Horsley) upon certain Government officials. Such a step on the part of a British Minister suggests that he is not sure of his case or he would have resorted to ordinary legal methods, instead of appealing for vicarious punishment by the un-English method of secret information. It would be difficult to picture a more humiliating position than that of Mr. McKenna when the President of the R.C.S. informed him he had no jurisdiction in the matter. As to the College, Sir Victor Horsley calls it roundly an "archaic" institution. Here, again, there is probably much truth in his assertion. Our medical corporations have not progressed with the times, and are in want of reform to bring them into line with modern views. To think of a Home Secretary appealing to the Royal College of Surgeons to punish certain of its members for a political offence! The situation is worthy of Rabelais. Possibly Mr. McKenna has done the medical profession an unintentional service by calling public attention to the hopelessly decrepit constitution of that ancient medical corporation.

Malingering under the State Insurance. FROM the first it was recognised that one of the difficulties, from a medical point of view, in the way of a smooth working of the National Health Insurance Act would consist in the early detection of cases of spurious illness. It seems that some of the approved societies are already taking fright at what appears to be, in many quarters, an undue number of claims upon their resources, and, indeed, the gravity of the situation was hinted at the other day by Mr. Leishman, the chairman of the Scottish Insurance Commissioners, at the Scottish National Conference of Affiliated Friendly Societies held in Edinburgh. Human nature being what it is, there need not be much occasion for surprise that malingering is said to be "practised in a wholesale fashion." The temptation of having no work to do with ten shillings a week is not easy to resist for a low-grade workman, while the 7s. 6d. of sickness benefit granted to women affords a welcome addition to the family earnings. Though it is probable that true malingering is on the increase, it is probable that many patients under the Act place themselves unconsciously within that category for the simple reason that they are under the impression that they have a certain right to participate in the large sum of money which they believe is available for their express need, real or imaginary. It is said that women are greater offenders in this respect than men, and it is significant that public warnings have been given by prominent officials of approved societies, both in

London and in Edinburgh, with regard to the character of the claims made by women for sickness benefit.

Should Medical Referees be Appointed?

Other countries where State insurance is in vogue have had a similar experience, for it is common knowledge that valetudinarianism, if not conscious malingering, has caused a rapid growth in that country in the expenditure upon medical and sickness benefit. From the financial aspect, therefore, the question becomes a serious one for those responsible for the administration of the Act. Something must be done, and done quickly, to prevent undesirable leakage in the national fund designed for the relief of those in real necessity. The appointment of special medical referees or advisers whose duties would include the special examination of such applicants as might be referred to them by an Insurance Committee would go far to weed out the real from the sham cases of illness. It is understood that the question of such appointments is already under consideration by the London Insurance Committee, though it remains to be seen whether the general terms of the appointments are likely to be acceptable to their holders or to the medical profession as a whole. If medical referees are to be appointed at all it would be desirable that they should be of the same professional standing as, for instance, chief medical examiners to life insurance companies, or medical referees under the Workmen's Compensation Act. Their duties of examining patients and checking certificates would, no doubt, frequently involve them in delicate relationships with their fellow-practitioners, with the approved societies, and with the patients themselves. Needless to say, any medical referee should be answerable to the Insurance Commissioners only of his own district and not to any society.

The Extermination of Sleeping Sickness.

A communication of great importance was made last week to the African Society by Dr. Warrington Yorke, of the Liverpool School of Tropical Medicine. His paper dealt with the relation of sleeping sickness to big game, and it was followed by a debate of a highly interesting and valuable nature. Dr. Yorke stated that although sleeping sickness had been known on the West Coast for nearly 200 years it was unknown in Nyassaland and the greater part of Rhodesia until 1908; but now a large number of cases existed amongst Europeans and natives in those districts. In 1910 it was discovered that the parasite was of a new species and it was named the *Trypanosoma rhodesiense.* With a view of ascertaining what was the chief vertebrate reservoir of the virus, 250 wild animals were examined, including elephant, lion, rhinoceros, hippopotamus, antelope, squirrel, monkeys, rats, mice, and many others. As a result of this investigation it was found that at least 50 per cent. of game and of domestic animals at Nawaha, in the Luangwa Valley, were infected with the trypanosome. Now, as the essential factors of the spread of sleeping sickness are the trypanosome, the *Glossina morsitans* or tze-tze fly and the human being, the extermination of the malady from a given district is narrowed down to a three-cornered problem. It is obviously difficult or impossible to attempt to clear great areas of country of the brush that harbours the fly. The remaining alternatives are to shift the population or to destroy the wild animals, notably the big game, which play host to the parasites.

A Scientific Experiment Wanted.

To depopulate a region would be to convert it practically into a huge game preserve, and it is reasonable to suppose that the tze-tse flies and the trypanosomes would thrive and multiply under such circumstances. It is suggested that a decisive scientific experiment should be made to ascertain the effects of completely eradicating the game within a given area. As some years must elapse before the results of such an experiment could be ascertained, Dr. Yorke suggested that in the meantime the restrictions on killing game by Europeans and natives should be removed in those portions of the fly areas in the vicinity of human habitations. Dr. Yorke stated that as the result of careful examination of small vermin—rats, mice, wild rabbits and so on—by himself and Dr. Kinghorn, he failed to find a single instance of infection. The infection therefore appears to be more or less limited to the big game. The pith of his recommendation was not to kill off the big game completely, but to consider the advisability of driving back the game from inhabited regions. In the discussion which followed Dr. Yorke's paper, Sir Ronald Ross made the pregnant suggestion that experiments were wanted with regard to the destruction of the germ in man.

LEADING ARTICLES.

MARRIAGE, BIRTH, AND DEATH RATES IN 1912.

Of late years the Annual Summary of the Registrar-General has had a special interest in view of the steady decrease in the birth-rate which has characterised the present generation. The problem strikes deep into the roots of our national prosperity, nay, of our very existence. It is not confined to the United Kingdom, for statistics show that our own experience is merely part of a world-wide movement. The diminution of the birth-rate cannot be grasped in its full significance without weighing its relation to the marriage-rate and the death-rate. The facts recorded by the Registrar-General for the year 1912 are, briefly, a birth-rate of 23.8 per 1,000, showing a fall of .8 compared with the figures for 1911, and 3 less than the average for the decade. Were this progressive diminution in the number of children born into our population taken alone, it would indicate a situation little short of national jeopardy. Fortunately, however, there are other facts which somewhat mitigate the anxieties of the position. The low birth-rate is accompanied by a constantly decreasing death-rate which has now touched its lowest record in 13.3 for the year 1912, or 1.3 less than in 1911, or 1.9 below the ten years' average. So that although fewer children are added to the population their average expectation of life is increased. Then, again, the decrease in the death-rate mainly applies to infantile mortality, which means that although fewer children are born, a large proportion of them survive into adult life. This decrease of infantile mortality is one of the encouraging modern features of preventive medicine, but although a great deal has been achieved in that direction during the past ten or fifteen years, the returns still show an excessive preventable mortality amongst children. The question of quantity must be considered along with that of quality. It is obviously better for the community that a small number of healthy children should be produced than many weaklings. The science that may one day govern and control this phase of the problem, namely, eugenics, is still in its infancy, but signs are not wanting that one day society will recognise that it is entitled to ask that individuals who contemplate the mutual procreation of offspring should first prove their presumable fitness for a function that possesses a vital importance to the common weal. From a medical point of view any course of action that deliberately incurs the risk of the production of unfit children is logically indefensible. Before the recent Royal Commission upon Divorce and the Marriage Law, a medical witness advocated the desirability of a voluntary medical certificate of fitness in the case of each party to a proposed marriage contract. That suggestion, if a recent newspaper report be accredited, is at the present moment being enforced in New York. A further suggestion from the same source was that a special section be added to the existing labour bureaux for the purpose of giving skilled advice to all persons contemplating marriage. That suggestion has been actively applied in a South London district. Another aspect of the diminishing birth-rate that must be faced is the growing disinclination of parents to produce large families. Limitation of this kind is, after all, in its ultimate analysis, simply the expression of some underlying social force from which it is a difficult or impossible task to disentangle economic, moral, religious and personal factors one from the other. The fact remains that the birth-rate goes on diminishing year after year, while the marriage age is becoming later, and on the whole the balance of the actual population is increasing, but at a less rapid rate than that rendered possible by half a century of national prosperity and of comparative freedom from wars on a large scale. It seems inevitable that man with his increasing domination of the resources of that world in which his intellect has been evolved must sooner or later assert a reasoned control over the most vital of racial problems, namely, the production of a population physically fitted for the stress of modern civilisation. From that standpoint the limitation of production demands to be considered impartially as if it were a problem in mathematics. Science or no science, the matter has been settled independently by a large section of the community, and presents itself in concrete form for scientific investigation.

Dr. R. M. Beaton has been appointed an additional medical member of the London Insurance Committee by the London County Council.

CURRENT TOPICS.

Ghosts.

When we hear of anybody having seen a ghost our first impulse is to explain the matter away. There are more explanations of supernatural visitors than records of their visitations. Theories ranging from the distorted vision of a coat hung on a chair to elaborate conceptions of a race of beings who inhabit a world of four dimensions and occasionally slip down to one of ours, are thrust at us when we try to indulge in a mild orgy of child-like faith in our senses. We are not allowed to believe in ghosts. A Boston house was haunted in the best sense of the word. Horrid shapes and shrieks and sights unholy were its nocturnal lot. The inhabitants enjoyed a pleasantly terrified notoriety and the reporters of the yellow press exulted in featuring their investigations of the phenomena. To them enters a sanitary inspector. Looking round in his solemn official way he found a defective flue which flooded the house with a malodorous mixture of sulphurous oxide, carbon monoxide, and other ingredients. The haunted inhabitants were suffering from a chronic intoxication that affected their bodily health and their imagination. *Hinc illæ vapores.* The methæmoglobinic householders have our sincere sympathy. To be poisoned is bad enough, but it is really too bad to have one's most cherished spiritualistic visitors reduced to a thin airy shoal of visionary ghosts whose origin is a leaky stovepipe.

The Rob.

The *Medical Record* prints an article on a composition that played a prominent part in the history of secret remedies. The product is an alleged non-mercurial anti-syphilitic specific called "the rob," and has been sold without a break from 1761 to 1910, and is probably still on the market. To the syphilitic at the time of its introduction salivation and salvation were synonymous, and the symptoms of mercurial poisoning were frequently found and confused with the effects of lues. The rob was sanctioned by the Royal Medical Society of Paris, was approved by Louis XVI., and Napoleon offered the inventor 1,000,000 francs for the secret of its composition. The firm that first introduced the remedy split, and rival products were placed on the market. One of these houses published a formula which contains some thirty vegetable ingredients. Analysts from 1770 till to-day have failed to find mercury in the preparation, but many physicians have asserted that they have noticed salivation in patients who were taking no other drug. How much virtue there was in the stuff it is hard to say. Of course, the secrecy is often the most potent factor for efficacy in a proprietary medicine. It may be mentioned here that the name "rob" is Arabic in origin, meaning "a confection of joint juices," and is not an example of unprecedented commercial candour.

X-Rays in the Diagnosis of Gastric Ulcer.

The introduction of radioscopic methods and the bismuth meal has revolutionised, to a great extent, our knowledge of gastro-intestinal affections during the past few years. The subject of the use of the X-rays in the elucidation of some of the problems of gastric ulcer was dealt with at a recent meeting of the Electro-Therapeutical Section of the Royal Society of Medicine by Dr. Alfred C. Jordan and Dr. A. E. Barclay. The former reviewed the radiographic signs of chronic gastric ulcers, and called attention to the appearances seen in a typical case of ulcer at the pylorus. These are pyloric stenosis, or pyloric spasm in earlier cases, leading to gastric dilatation, and, in addition, the phenomenon of reversed peristalsis. In the case of duodenal ulcers, it has been amply demonstrated that the cause which lies at the root of the trouble is intestinal stasis, and there can be little doubt that this evil is also largely responsible for gastric ulcer. Duodenal distension occurs, and this increases the work of the stomach in forcing its contents through the pylorus. The mechanics of the subsequent stages in the process by which an ulcer is formed in the stomach have been fully explained by Sir Arbuthnot Lane. Chronic ulcers of the lesser curvature present a striking picture, the most prominent feature of which is the firm spasmodic contraction of the circular fibres of the stomach over the area of the ulcer, giving rise to a tight, hour-glass constriction, which is permanent, except under an anæsthetic. The theory of gastric spasm, set up in the first place by swallowed septic matter, aided by the action of the gastric juice and the mechanical irritation of food, has impressed Dr. Barclay, whose radiographic experiences lead him to regard a definite organic lesion as an easy transition from an apparently simple spasmodic condition. At any rate, we possess in the X-rays a valuable additional means of diagnosis in cases of ulceration of the stomach and duodenum.

Medical Men's Hobbies.

A perusal of certain publications containing the names, not always representative, of medical practitioners furnishes many interesting personal touches regarding the individual thus listed. For instance, we are informed that Dr. A. finds his pleasure in "rambling in search of microscopical life," while Dr. B. is not satisfied unless he can "hunt for big game"—in his holidays, presumably. Tastes differ, of course, and while one man may revel in collecting antiquities, another may find his highest joy in being propelled across the country at fifty miles an hour in a motor-car. Sometimes, indeed, the "lesser thing in life may take the lead," and the medical man's rightful calling fades into the background as his hobby gradually usurps its place. There are numerous instances where this transposition of occupation has occurred, resulting in the evolution of a poet, a scientist, an author, or, perchance, a musician. An interesting account is given by Dr. Henry M. Church (*a*) of Linnæus as a physician, and it may be urged that had this distinguished "Pole Star of Botany" neglected his study of plants, which at one time was purely secondary to his medical practice, the world would have been deprived of one of the greatest naturalists it has ever seen. But Linnæus himself, we are informed, so soon as his position as a botanist was established, began to cultivate a lesser study, or rather a recreation—that of collecting portraits. Apart from the possibility of distinguishing one's self in more than one calling, the value of a real hobby is its sweetly distracting power over the mind when jaded with the toils of everyday work. Every man to his trade is a good rule of life; but everyone to his hobby, as the French say, is equally true.

Medical Certification in Ireland.

It is time that the Irish Insurance Commissioners would give up their pretence of making arrangements for certification in Ireland by the employment of salaried "certifiers." The panel system was first attempted, but was refused by the medical profession in the greater part of the country. In Dublin some half-dozen medical men put their names on the panel in opposition to the wishes of their colleagues. The boast that certification was thereby provided for has already been abandoned, and the panel is no more. The same half-dozen, however, with the addition of as many more, now constitute the "Board of Medical Advisers." The humbug imposes on no one. The Dublin Insurance Committee has repudiated the "Board," and the societies are not likely to appraise it at any higher value. The attempt on the part of the Commissioners to oust medical practitioners from recommending their patients for sanatorium benefit, and to introduce the "medical advisers" for this purpose, is likely to endanger the working of the only part of the Act which up to the present has been a success. So far the administration of the sanatorium benefit has had the cordial co-operation of all medical practitioners. There are signs, however, that the patience of the profession is wearing thin. If the Commissioners, by their attempt to shove their "advisers" between the medical man and his own patient, bring about an open revolt, they have only themselves to blame for hanging up the benefit.

The Systematic Study of Chronic Diseases.

From the first days of his work in the wards of a hospital the medical student is impressed with the superior claims of acute over chronic affections. The acute case, from the fact that it is acute, is given preference of admission into most hospitals, while the poor "chronic" often has to make shift with less comfortable quarters to make room for the newcomer. It is often the case that clinical teachers, especially members of a junior hospital staff, find more "points" for examination purposes when going over an acute case with a class than when confronted with a chronic nerve or heart case. Hence it is that, little by little, a sort of distaste for the study of all cases of chronic disease is acquired. It is perfectly true, of course, that there is frequently nothing fresh to observe about such cases, so that ward-clerks, to whom medical report-writing may be a burden, have cause for rejoicing when taking over a series of chronic cases from their predecessors in office. A correspondent in the *Morning Post* has recently pointed out what he considers is a medical anomaly—namely, that under the present system cases of long incapacitating illness can rarely be followed up to their termination by members of hospital staffs. The Poor Law Infirmaries, excellent institutions as they are, might well, this writer believes, be served by skilled investigators and specialists in a similar manner to the voluntary hospitals. In this way it is urged that the infirmaries would become important centres of clinical teaching and also of pathological research, while the effect upon medical education in general would be far-reaching. The suggestion is not a new one, and there are a number of technical difficulties in the direction of administration, which would have to be overcome before any workable arrangement of the kind could be inaugurated. Nevertheless, such a movement could not fail to benefit both the medical profession and the public.

Human Asymmetry.

The statement made by a medical witness in a recent law case to the effect that no person possesses legs of equal length has excited the usual paragraphs of surprise in the lay Press. It is well known to medical men that perfect symmetry of form exists only in the painter's or sculptor's imagination. Even the so-called "perfect woman," who exhibited herself some time ago at one of the London places of entertainment, would, no doubt,

---

(*a*) *Edinburgh Medical Journal*, June, 1913.

present some fractional difference in the length, or other dimension, of the limbs when scientifically measured. In many cases this asymmetry is quite marked, especially of the features, one ear being set higher in the head than the other, or one side of the face may be smaller than the other, apart from such defects as that of a deflected septum nasi. The influence of habit is, to a large extent, responsible for this inequality. As long as man is, for the most part, ambidextrous, he will continue to perform certain movements with his right hand alone, or more than the left, which are not without influence even upon the features. Every good portrait-photographer is familiar with these facial variations, and the skilful artist is he who successfully prevents such trivial defects from being noticed in the finished picture. If a certain amount of asymmetry is normal to the majority of healthy people, it is far more commonly seen in disease. The atrophy of a paralysed limb, the shortening of a leg from joint disease, the retraction of one side of the chest in certain chronic lung affections, are only a few examples of morbid asymmetry that will occur at once to the medical mind. An interesting sidelight from the point of view of heredity is the occurrence of such variations as differences in the colour of the eyes in the same individual.

The Problem of the Consumptive Lodger.

Since public opinion has been more or less aroused as to the infectious nature of pulmonary tuberculosis, many new problems have presented themselves for solution, both legally and socially. One of the most important of these concerns the lodger who is affected with consumption, and who may find himself in a very awkward position by reason of his infirmity. Now that tuberculosis has become a notifiable disease, people are beginning to fight shy of having consumptives, particularly strange lodgers, in their houses. It matters not whether the disease be, strictly speaking, in the infectious stage or only incipient and devoid of expectoration, it has got wind that the case has been notified, and the unfortunate patient may be requested to seek other lodgings as hastily as though he were afflicted with leprosy or diphtheria. An interesting legal decision was given the other day at the Monaghan Quarter Sessions by His Honour Judge Johnston, when a Rostrevor boarding-house keeper sought to recover damages from the executor of a deceased lodger for damages committed by him when residing in her house for a specified period. It was alleged that he "infected the house and furniture with a contagious disease." He was admitted as a lodger as suffering from congestion of the lungs, whereas he was affected with advanced consumption, and on the second morning he had a sharp attack of hæmoptysis. The plaintiff's case was that three of her other lodgers left, and she was unable to let for the rest of the season, and that a breach of warranty in not informing her of the nature of the deceased man's true illness had been committed. At the time of the letting the plaintiff required a statement as to whether the deceased was suffering from consumption, and she was assured that he was not. It was held that this assurance was what the law knows as a warranty. Under the circumstances, the learned judge awarded the plaintiff the full amount of her loss.

As we go to press we regret to learn the death of Mr. Alfred Willett, F.R.C.S., Consulting Surgeon to St Bartholomew's Hospital. We hope to publish a full obituary in our next issue.

PERSONAL.

H.R.H. Princess Louise, Duchess of Argyll, laid the foundation stone of the South London Hospital for Women (Incorporated), South Side, Clapham Common, yesterday afternoon.

Dr. H. W. Barnes has been appointed Assistant Medical Officer of Health for the City of Lincoln.

Mr. J. A. Craig, F.R.C.S., has been appointed Lecturer in Ophthalmology in the Queen's University of Belfast.

Dr. Jehan M. Barlet, M.D.Brux., L.R.C.P.Lond., M.R.C.S., has been appointed Anæsthetist to the French Hospital, London.

Sir Robert H. Woods, of Dublin, was the recipient of the honorary degree of M.Ch., of the University of Dublin on the 26th ult.

Dr. E. M. Brockbank, Honorary Physician to the Manchester Royal Infirmary, has been appointed Dean of its School for Clinical Instruction.

The Postmaster-General has appointed Dr. J. Sinclair to be Chief Medical Officer to the Post Office in place of Dr. A. H. Wilson, who is retiring under the age limit.

Professor A. C. Geddes, of the Royal College of Surgeons in Ireland, has been appointed to the Chair of Anatomy in McGill University, Montreal. Professor Geddes will take up the duties of his new post in the autumn.

Among the names of the scholars who have been awarded Science Research Scholarships by the Royal Commissioners for the Exhibition of 1851 is that of Dr. John Charles Johnson, M.A., M.B., M.Sc., of University College, Cork.

Mr. W. H. Clayton-Greene, F.R.C.S., Surgeon to the French Hospital, London, was personally decorated with the Cross of the Legion of Honour by the French President last week upon the occasion of the visit of the latter to the institution.

Dr. Alice Hutchison, of Edinburgh, was entertained last week at a complimentary dinner on her return from the Balkan seat of war. Our scotch correspondent gives some interesting particulars of this lady's experience in the convoy corps in another column.

The annual general meeting of the Poor Law Officers' Association of England and Wales will take place to-morrow, July 3rd, at 3 p.m., in the rooms of the Medical Society of London, Chandos Street, W., when Dr. C. Thackray Parsons, Medical Superintendent of the Fulham Infirmary, will read a paper on "The Present and Future of the Poor Law Infirmary."

Dr. Leonard. D. Gamble, of Ambergavenny, who is leaving shortly for the Orange River Colony for the benefit of his health, was presented the other day on behalf of the inhabitants of the district with an illuminated address and a purse of £200, as a token of the esteem and affection with which he had always been regarded when in practice among them.

The French Government, through the Minister of War, has just conferred on Mr. Adolphe Smith, F.C.S., the Commemorative Medal of the campaign of 1870-71, instituted by the law of November 9th, 1911. Mr. Adolphe Smith, who has been on the staff of the *Lancet* for many years, served during the siege of Paris under the distinguished surgeon, Dr. Léon Labbé, and took part in several of the battles which were fought under the walls of Paris. During the retreat from Buzanval he came across the late Sir William MacCormac, and was able to render him assistance when under fire in the village of Ruel.

CLINICAL LECTURE

ON

ABSENCE OF ABDOMINAL RESPIRATORY MOVEMENT AS AN INDICATION OF PERICARDITIS. (*a*)

By W. ESSEX WYNTER, M.D., F.R.C.P.Lond.,

Physician to the Middlesex Hospital.

IN January, 1911, I read in the Medical Section of the Royal Society of Medicine a short paper on Absence of Abdominal Respiratory Movement as an indication of Pericarditis, pointing out that though "in the majority of thoracic cases affecting the lung and pleura this is one-sided, and the influence on abdominal movement proportionately less marked," in acute pericarditis the cessation of phrenic action is bilateral, and consequently absence of abdominal movement is as obvious as in abdominal disorders, though rigidity and general tenderness are for the most part lacking.

The two cases first cited illustrated this point in a very striking manner, in that the remarkable stillness of the abdomen led to the diagnosis of acute abdominal lesions, the pericarditis being discovered later. The first, seen in October 1905, was a young Irishman, in the service of a medical friend, who had been seized with acute epigastric pain while waiting at table. Conspicuous absence of abdominal movement led to the supposition that he had a perforated gastric ulcer, and I was asked to take him into hospital for operation. The observation and inference had been made by an independent local practitioner, and was quite disinterested as regards pericarditis, which was not thought of at the time.

Next morning the pain had subsided, he had slept fairly, and was obviously better, clamouring for food, and impatient of restraint. There was no evidence of free gas in the peritoneum or of local irritation. A routine examination revealed nothing. Next day he got up and went out of his own accord, but experienced a recurrence of his pain. When re-examined on the fourth day pericardial friction was quite obvious. There was then dyspnœa and præcordial pain, the abdomen remaining immobile. Pericardial murmur was audible four days, temperature 101.4, pulse 96. On getting up a week later temperature rose to 103 and pulse 104, but no further development occurred, and he was able to leave the hospital after a stay of three weeks.

The second case, seen in November, 1909, was a man, æt. 40, admitted with complaint of pain in the abdomen extending to the thighs—headache, anorexia, vomiting and parched mouth of two days' standing; temperature 102.6, pulse 92. He lay on his back with his legs drawn up. The right rectus abdominis was tense and there was some tenderness in the right iliac region. Abdominal respiratory movement was scarcely discernible. The only thoracic sign present was a reduplicated second sound. No local indication of pericarditis then existed. Five weeks after the original attack an operation for appendicectomy was performed, but careful examination revealed no morbid condition, and there were no adhesions. The incision healed rapidly, but after five days there was a rise of temperature with recurrence of symptoms and pericardial friction was recognised. The diaphragm was not contracting at all, the abdomen actually sinking in with each inspiration. Pulse 90 to 100. The stomach was dilated, and its resonance could be traced as high as the fourth intercostal space in the axilla. Breath sounds were absent at both bases, but there was no complete dulness on percussion. Under the X-ray screen a large shadow could be seen in the heart region, suggesting pericardial effusion. The diaphragm was motionless in the position of expiration. Ten days later movement of the diaphragm was returning, though friction could still be heard over the heart. Breathing became audible at both bases, and the patient was discharged a month after the first appearance of the pericardial friction.

Both these cases illustrate the independent observation of loss of abdominal movement as a precursor of pericarditis, and likewise the temporary remission of symptoms attending rest in bed. They also suggest that inflammation of the pericardium, possibly commencing on the diaphragmatic surface, caused reflex inhibition of movement some days before the appearance of the ordinary clinical signs over the præcordia.

Ten other cases were subjoined in which loss of abdominal movement had been conspicuous, some with screen examinations demonstrating the stasis of the diaphragm, and three showing evidence of pericardial effusion. In one case the contents of the upper abdomen, such as the kidneys and opaque masses in the intestines, could be seen to participate in the upward inspiratory movement, for in this the diaphragm actually rose with inspiration instead of descending, following the aspiration of the upper chest.

Associated phenomena are dilatation of the hollow abdominal viscera, especially the stomach, and collapse with loss of function of the lower lobes of the lungs, with slight upward displacement of the heart.

Loss of abdominal movement, as a sign of pericarditis, is the more valuable in that it may precede and outlast the other indications, and so afford grounds for anticipatory or retrospective diagnosis. The condition of diaphragm paresis affords a reasonable explanation of the cyanosis and dyspnœa so usual in the complaint and of the upright position so commonly assumed by the patient: the former expressing the effect of respiration restricted to the function of the upper lobes of the lungs, and the latter pointing to an unconscious effort on the part of the patient to utilise the weight of the abdominal viscera in depressing the passive diaphragm and enlarge the thoracic area.

(*a*) Delivered at the London Polyclinic, May 13, 1913.

Restriction of abdominal movement was apparently more marked with a fibrinous exudate than with effusion, in this respect being parallel to similar affections of the pleura or peritoneum.

The detection of a limited amount of effusion in some of the cases by X-ray examination was a new discovery, though it can readily be understood that two or three ounces of serum gravitating to the back or bottom of the pericardial sac would give no evidence of its existence by the ordinary method of percussion over the præcordia.

The conclusion in regard to these cases was, that where loss of abdominal respiratory movement was well marked, in the absence of more obvious thoracic and abdominal lesions, pericarditis should be closely looked for, and when this sign was wanting, dubious indications of pericarditis might be discounted.

Since formulating this statement rather more than two years ago I have met with thirty cases in my hospital wards, containing fifty beds, in which the loss of abdominal respiratory movement has led to the detection of pericarditis—a number so much in excess of those usually noted that it at once demonstrates the value of such a sign in assisting to recognise a very obscure condition, and strongly suggests that numbers of instances of pericarditis have hitherto been overlooked. This is not altogether incredible in view of the favourable course usually followed by the commonest form, rheumatic pericarditis, without excess of effusion, and is entirely in accord with the dictum of pathologists that affections of the pericardium of all kinds are recognised far more frequently in the *post-mortem* room than in the wards, which is tantamount to saying that even the most severe cases are commonly overlooked during life.

But it is not merely to redress the discrepancy between the clinical and pathological aspects of pericarditis that this sign is of value.

There are many instances of primary illness otherwise unexplained, as well as exacerbations in the course of other complaints, and terminal phases proving fatal in chronic maladies, where the timely recognition of pericarditis, which is the dominant factor, would dispel a great deal of mystery and uncertainty, and might relieve much suffering and even prolong life.

Terminal cases are represented by the only ones, four in number, that proved fatal. None were rheumatic.

A young woman of 21 was admitted with pueperal sepsis, which proved fatal on the third day after admission.

Abdominal movement was absent.—There was evidence of effusion in the right pleura and friction could be heard over the pulmonary cartilage. Pericarditis was diagnosed. At the autopsy the pericarditis was demonstrated and O.i. fluid in right pleura, containing streptococci.

On the first of the present month of May a young woman of 18 was admitted in a state of orthopnœa. The temperature was subnormal. The urine 1015, free from albumen (30 oz.). There was much restricted abdominal movement, and friction could be heard to right and left of sternum, both pericarditis and left pleurisy being present. She died May 4th, and at a *post-mortem* examination the lesions of the pericardium and pleura were verified. They were secondary to small white kidney and uræmia, the heart weighing 14 oz.

Two other cases proved fatal in children of 5. One complicated with purpura and parotitis, but presenting well-marked friction and cantering rhythm over the præcordia. This was septic. The other displayed not only to-and-fro friction over the heart, but effusion was recognised by the aid of the X-ray screen. Unfortunately she developed acute œdema of the lungs and died very rapidly. Both cases exhibited marked restriction of movement in the abdomen.

As no *post-mortem* examinations were permitted there was no ocular demonstration of the pericarditis, though no reasonable doubt existed.

In four cases the pericarditis was associated with chorea in children. Two were admitted with this complaint, and evidence of pericarditis either in to-and-fro friction or cantering rhythm with loss of abdominal movement.

Another, admitted with rheumatism and mitral regurgitation, developed chorea, and at the same time loss of abdominal movement was noted and pericarditis recognised by well-marked friction at the base of the heart. When re-admitted for recurrence of chorea three months later the pericardium was found to be adherent. The fourth case, admitted with chorea, later developed pericarditis and effusion.

Abdominal respiration was abolished and the X-ray screen demonstrated the stasis of the diaphragm and a non-pulsating shadow surrounding the heart, representing effusion. All these were discharged convalescent.

Next to *post-mortem* evidence of pericarditis comes that of paracentesis of the paricardium, very infrequently called for, and still more infrequently performed.

H. M., a boy, æt. 13, was admitted for rheumatism and mitral regurgitation on November 1st, 1911.

There was restriction of abdominal movement and præcordial pain. Temperature 100, pulse 108. Friction was discovered at the base of the heart. On November 3rd an extensive non-pulsating shadow was seen by the X-ray screen in the cardiac area. In spite of local and general treatment by salicylates, the area of dulness over the pericardium increased, and the patient became much distressed.

On November 13th paracentesis was performed. Under a general anæsthetic, given with great caution, the aspirating needle, 4 ins. long, was introduced ½ in. outside the sternum in the fourth right inter-chondral space, being directed horizontally backwards and inwards so as to graze the back of the sternum. By this path, as you may see by looking at this specimen from the front of the chest, the needle passes internal to the mammary vessels, and entering the pericardium about the middle line, avoids either pleura. The needle was inserted about 2 in., and without any difficulty some 2½ oz. of blood-stained fluid were withdrawn. Immediate relief followed, and the boy was subsequently discharged convalescent.

This and the remaining cases were all rheumatic. These run usually a favourable course, and in most instances being included in the general treatment by salicylates would not greatly suffer if the pericarditis were overlooked, as commonly happens. In a fair number of cases, however, the pericarditis develops late in the attack, not infrequently while the patient is regarded as convalescent, and sometimes is the cause of delayed convalescence or apparent relapse.

For instance, a man, æt. 27, was admitted on December 28th, 1912, having been laid up with rheumatism six weeks. Getting alarmingly worse he was brought to the hospital, and it was at once noted that abdominal respiration was absent. There was an apex systolic and a double aortic murmur, which made the detection of pericardial friction increasingly difficult. The screen, however, confirmed the diagnosis of diaphragm stasis and excluded effusion in the pericardium. His recovery took six weeks.

One case, a young woman, æt. 23, was reclaimed from a surgical ward where she was admitted on account of loss of movement and rigidity in the upper abdomen, suggesting peritonitis. No physical signs were detected in the chest, but next day there was a well-marked pericardial rub in the second left interspace. This was at first to and fro, but persisted as a crackling systolic bruit. I had the confirmation of Sir James Kingston Fowler that this was produced over the auricular appendix.

In six cases pericarditis developed some days or weeks after the patient had been admitted with rheumatism. The routine examination on admission satisfactorily excluding this condition, which, moreover, supervened with rise of temperature, sometimes to 104, and increased rapidity of pulse.

In two cases pericarditis was diagnosed, and local remedies applied on the strength of these signs, with loss of abdominal movement, and in both friction developed in 24 to 48 hours.

One case of double basic pneumonia with left-sided empyema developed pericarditis, indicated by loss of abdominal movement and præcordial friction, which subsided on draining the pleura, showing that, as in the pleura, an effusion of pneumococcic origin need not necessarily be purulent.

Perhaps the most signal instance of the value of this sign occurred in a young domestic servant who has only just left the hospital.

She had been laid up for three weeks with fever, dyspnœa and dulness at both bases posteriorly, and was considered to have had double basic pneumonia. On the fifteenth day, as the temperature had not fallen, and she was still very ill, it was thought she must either have an obscure, possibly interlobar, empyema or acute pneumonic phthisis. There was, however, loss of abdominal movement, and in spite of the long and severe illness, she was able to sit up to be examined. Moreover, there had been frequent sweating, the temperature had only once reached 103, and she was not as prostrate as would be expected after double pneumonia. An immediate screen examination disclosed stasis of the diaphragm, a pericardial rub having previously been detected. Local remedies were applied, and she made a rapid recovery. I have little doubt that this was an instance of pericarditis, probably rheumatic, associated with stasis of the diaphragm and collapse, not pneumonia of the lower lobes.

This altered aspect of the case, based on the abdominal symptoms, made all the difference in the prognosis as well as the treatment of the case, with the happiest result.

I have picked out these cases to illustrate special points. The bulk of those included in the survey of 30 in two years were ordinary rheumatic cases in children and young adults in whom pericarditis occurred as a complication, and was first suspected on account of loss of abdominal movement or where this sign was noted after finding the pericarditis. But I think they help to prove how constant this sign is and how very much commoner pericarditis is than was formerly believed.

In conclusion a few words may be added about the treatment of the common form of rheumatic pericarditis. Of course salicylates are the potent remedies, but I have long been convinced by the frequency with which pericarditis develops in patients already taking salicylates in the course of rheumatism that the internal administration is not sufficient. In all cases I apply an ointment of ʒii. salicylate of methyl in ℥i. lanoline to the præcordia, renewing it daily for four or five days till the temperature and other signs subside. It may be even necessary to omit the internal administration of salicylates if symptoms of over-dosage have appeared, but sufficient is absorbed through the skin to keep up the general effect besides concentrating its maximum influence locally. This remedy is effective in effusion as well as in cases exhibiting only friction, though the screen examinations show that in these, fluid, in small quantities, is often present when quite unsuspected.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Prof. Dr. O. Kukula, in Prag. Subject: "The Surgical Treatment of Epilepsy."*

ORIGINAL PAPERS.

INTESTINAL ANGULATIONS AND KINKS ASSOCIATED WITH STASIS. (a)

By W. I. de C. Wheeler, F.R.C.S.I.;
Surgeon to Mercer's Hospital, Dublin.

The profusion of recent literature on the subject of intestinal stasis produced by non-inflammatory intestinal adhesions and kinks, with all the varying and contradictory expert opinions put forward, renders it difficult to compile a communication in any sense complete.

In this paper, for the sake of brevity, it will be necessary to confine my remarks to personal experiences with twenty recent abdominal cases which illustrated conditions associated with the term intestinal stasis. Some or all of the pathological conditions which I mention later in the paper were present in my series of cases.

It is not so long since we were taught that intestinal kinks and adhesions other than inflammatory were a product of the imagination—" A dagger of the mind, a false creation." Those who were first to discount the possibility of the presence of kinks and adhesions have now taken refuge in the statement that every individual has adhesions and kinks, and they do no harm. These two contentions are obviously impossible to adjust or harmonise.

It may be now taken as an axiom that in a large percentage of abdominal cases, cases of gastric or duodenal ulcer, appendicitis, gall-stones, and allied conditions, including cystic ovary, there is present a varying degree of intestinal stasis associated with the presence of certain pathological angulations and kinks to be mentioned later.

(a) A paper read before the Section of Surgery, Royal Academy of Medicine in Ireland, May 9, 1913.

In a certain proportion of the cases these conditions, *per se*, give rise to no symptoms whatever, in others the symptoms are slight or masked; in the remainder they are so marked that a novice could not be deceived as to their cause.

The connection between, say, duodenal ulcer and intestinal kinks and other pelvic lesions is in dispute; that there is a close connection is beyond doubt, and it has led Moynihan to remove the appendix in most cases of duodenal ulcer, and Lane to abandon the operation of gastro-enterostomy except for the relief of pyloric obstruction. From the admitted association of various intra-abdominal lesions there is one practical lesson to be learnt—the fallacy of performing very rapid operations for the removal of a non-suppurating appendix. If the appendix is in an anatomical position, free from pathological adhesions, and lends itself to rapid removal, either the operation is not justified or, more likely, the symptoms which called for the operation were due equally to other associated abnormal conditions. Surgery has been discredited by the persistence of symptoms after removal of an appendix by surgeons ignorant of the existence, say, of a Jackson's membrane or other abnormality. The presence of a surprisingly normal appendix in a patient who suffered from symptoms sufficiently severe to warrant operation should call for pause, and a careful search be made for abnormalities at the terminal part of the ileum, the ascending colon, and hepatic flexure, and if need be in all "four corners" of the abdominal cavity. The removal of an appendix in four or five minutes is easy of accomplishment, but does not savour of scientific surgery, and the diagnosis of "Appendix Dyspepsia" in the light of recent advances in abdominal surgery can seldom be justified.

The following lesions were well marked in my series of cases, some in one, others in another; the presence of one abnormality did not necessarily mean the presence of another, although in several cases all the lesions to be mentioned were well marked and distinct in the same case. Thus, in some, appendicitis would be accompanied by a well-marked Jackson's membrane, a Lane's kink near the ileocæcal junction, and a mega-duodenum. In almost every case the terminal mesocolic kink (pelvic colon) was present, in some causing undoubted abdominal symptoms, in others doing no harm whatever.

Lane's terminal ileal kink was described as caused by a band first forming part of the under surface of the mesentery and afterwards a distinct ligament which attached itself progressively to the ileum more and more distant from the mesenteric border. The band is shorter than the mesentery, thus causing a pucker or kink of the ileum, which is, in addition, often rotated on its long axis owing to the attachment of the band to the anti-mesenteric border.

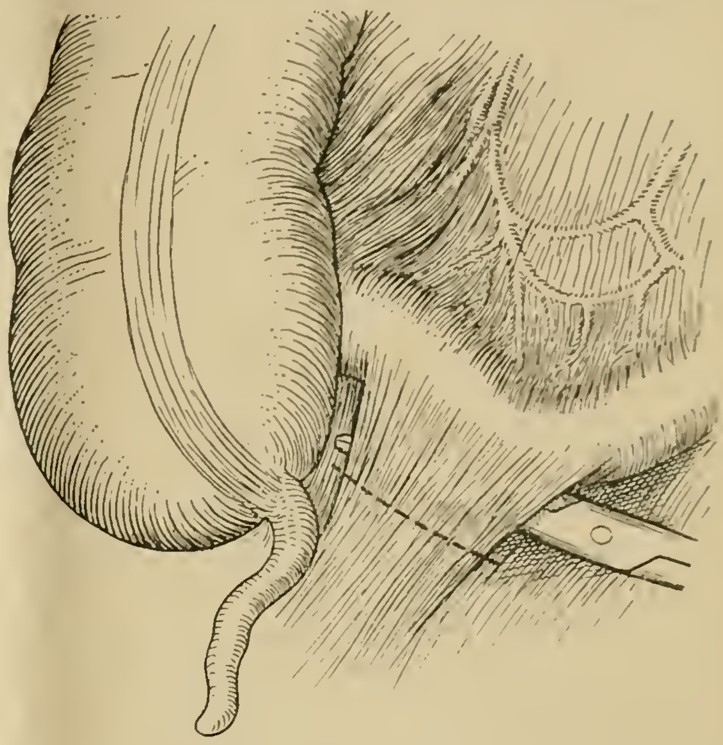

Fig. 1.—Diagram of Lane's Terminal Ileal Kink.

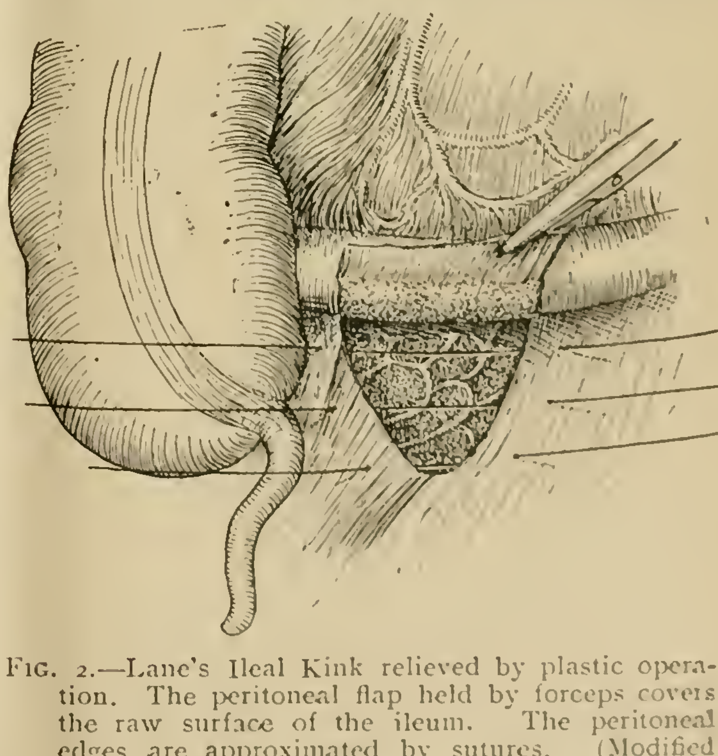

Fig. 2.—Lane's Ileal Kink relieved by plastic operation. The peritoneal flap held by forceps covers the raw surface of the ileum. The peritoneal edges are approximated by sutures. (Modified from Gray and Anderson.)

According to Lane, this and other intestinal kinks are due to "the crystallisation of lines of force" to prevent prolapse of the viscera in cases of chronic constipation. Gray and Anderson do not accept the explanation, and point out that in both the lower ileal and lower sigmoid kinks the mesentery and mesosigmoid show no evidence of "the crystallisation of lines of strain" in the upper layers where most strain would be expected, and that in a number of cases of ileal kink there was no tendency whatever to a dropped cæcum, which, on the contrary, was well fixed. In my cases of ileal kink, which were comparatively few, I could not satisfy myself that the small intestine was much, if at all, dilated above the lesion as described by Lane, but in two there was distinct evidence of mega-duodenum. This latter condition is produced not in any direct manner from the ileal kink, but by a similar adventitious formation at the duodeno-jejunal flexure, or to a band running across the duodenum just to the right of the superior mesenteric artery, as described by Murphy. Jackson's membrane has attracted considerable surgical attention during the past twelve months. It is a very obvious lesion found regularly in patients suffering from right-sided pain or discomfort with a loose, splashing cæcum, constipation, and some visceroptosis. It is present in other cases, but one soon gets familiar with a type of case where its presence can be foretold almost with certainty before operation. It is a thin, vascular veil, in which long, straight blood-vessels run a parallel course, compared by Jackson to an œdematous arachnoid. It is like a cobweb bag which is too small to hold the ascending colon without puckering it. It extends from the hepatic flexure to the cæcum, and may surround the colon on both sides of the anterior longitudinal band, merging below into the mesoappendix and pelvic peritoneum. At the hepatic flexure the membrane when lifted up on the finger often forms a formidable band binding and obstructing the colon.

The better developed the Jackson's membrane, the more prolapsed and distended is the cæcum. This is an observation of importance, for it teaches that it does not assist in fixing a mobile cæcum, but, on the contrary, by sometimes producing a very acute kink at the hepatic flexure of the colon causes dilatation and ptosis of the cæcum and ascending colon. It is noteworthy in these cases that the transverse and descending colon are collapsed in marked contrast to the cæcum and ascending colon. It is, therefore, more likely that Jackson's membrane is a cause, and not an effect, of intestinal stasis.

It is almost certain that Jackson's membrane is not inflammatory in origin. A study of the direction of the lymphatics proves it could not be a pericolic inflammation which had extended along the lymphatics of the subperitoneal coats. Furthermore, the blood-vessels run in a linear fashion, unlike those in inflammatory tissue, and no bleeding results from the general separation of the membrane, but, on the other hand, a sufficiently raw surface is sometimes left to necessitate the application of an omental graft to prevent subsequent adhesions. In young children Jackson's membrane is often well marked.

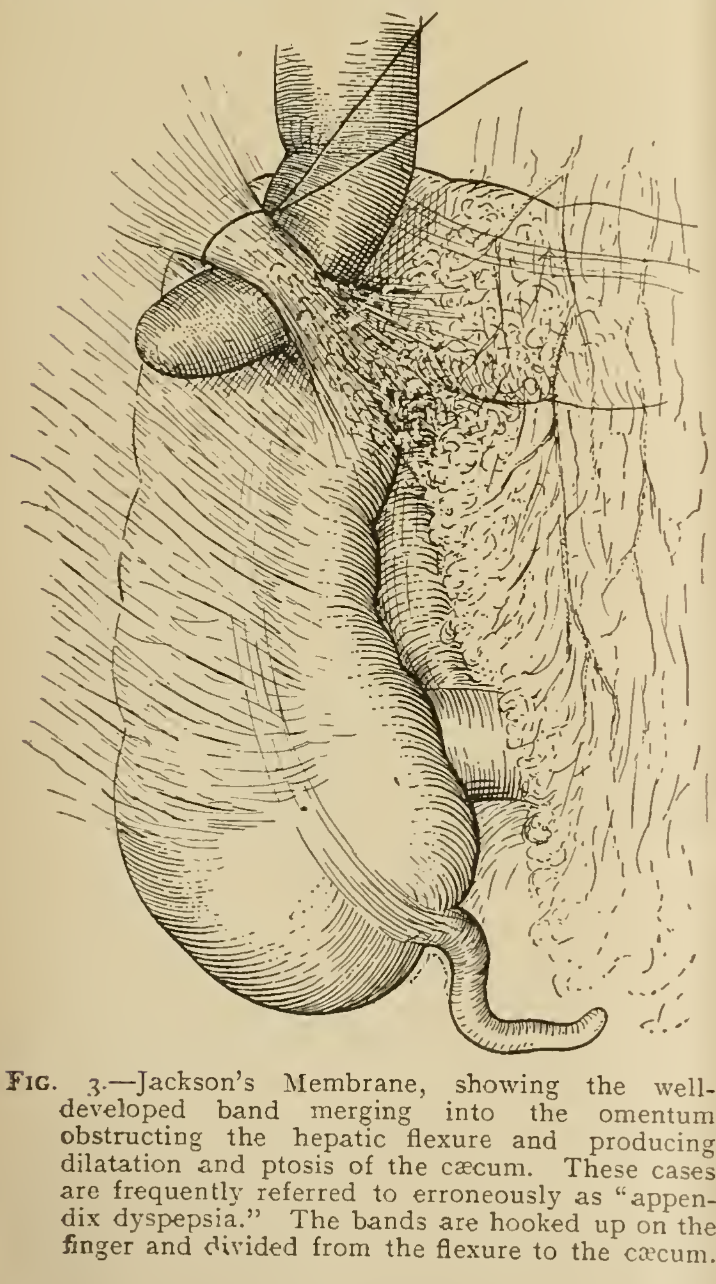

Fig. 3.—Jackson's Membrane, showing the well-developed band merging into the omentum obstructing the hepatic flexure and producing dilatation and ptosis of the cæcum. These cases are frequently referred to erroneously as "appendix dyspepsia." The bands are hooked up on the finger and divided from the flexure to the cæcum.

Mayo's theory of abnormal burrowing of the cæcum and lower end of the ileum during their descent from the liver under the parietal posterior peritoneum has been dismissed owing to the absence of such a process in the examination of a very large number of fœtuses.

Gray and Anderson's is the most fascinating explanation, and appeals to the imagination of those who have studied the structures at operations. They say the membrane is really the right margin of the great omentum. The omentum crosses the hepatic flexure and blends by physiological fusion with the posterior parietal peritoneum to the outer side of the colon. This fusion also takes place between the omentum and anterior wall of the colon near the longitudinal muscular band in the same way as the omentum finds attachment to the transverse colon in a corresponding position. During the descent of the cæcum the omentum crossing the flexure and becoming adherent to the parietal peritoneum externally gets pulled out, and is found in later life as the membrane already described. This theory is strengthened by the presence of fat, the linear arrangements of the vessels, and the site of attachment of the membrane to the colon. In several of my cases I could trace a direct and uninterrupted connection between the membrane and the omentum. This was specially noticeable above at the hepatic flexure, where Jackson's membrane often takes the form of powerful bands intermingled with fat, obstructing the onflow of the contents of the colon. (Fig. 3.)

In addition to the ileal kink, the hepatic kink produced by Jackson's membrane, the dilated duodenum already referred to, I have had one case of Payr's disease, where there was a well-marked kink of the splenic flexure, with dilatation and ptosis of the transverse and ascending colon, and collapse of the descending colon. It is, I believe, a comparatively common condition, but I have only seen it twice before, once in a case operated upon by a colleague before its significance was understood, and once with Mr. Gray, of Aberdeen. The kink is probably due to a shortened phrenocolic ligament.

In two-thirds of my cases the lower sigmoid kink was present. So frequently is this condition seen that it is looked upon as almost normal by some authorities. All are agreed, however, that in certain cases it produces very marked constipation and left-sided pain with dilatation of the colon above. In many cases, on the other hand, it interferes with the bowel little, if at all. Here we can see a beautiful example of a kink produced by the excess of physiological fusion as described by Toldt. (Fig. 4.)

Gray attributes the formation of all kinks to excess of physiological fusion, and it has been shown that the formation of Jackson's membrane can be attributed to a like cause. While Gray believes enteroptosis is produced by the presence of obstructive kinks, yet the congenital theory can be made clear by another interpretation.

When man assumes the erect position, in order to prevent a drop of all the viscera into the pelvis, nature, by physiological fusion of the visceral and parietal peritoneum, produces the splenic and hepatic flexures, the mesentery and mesocolon, and all ligaments intended to suspend the viscera.

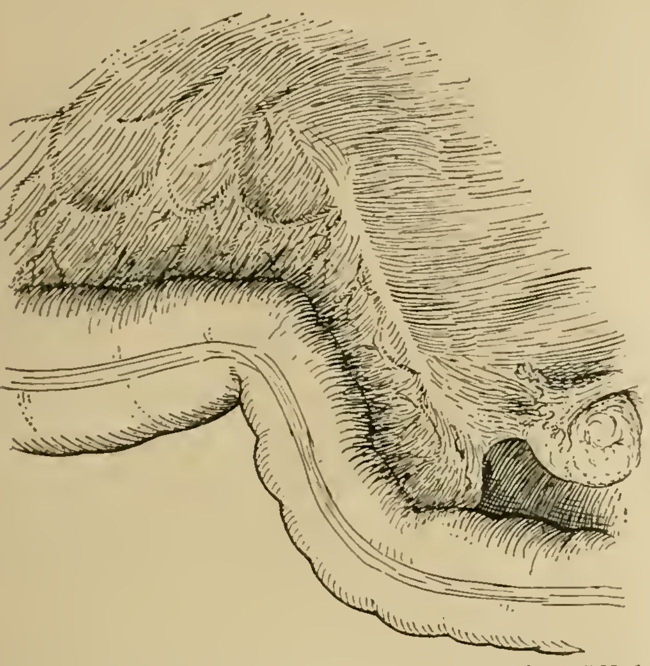

Fig. 4.—Kink of the Pelvic Colon, showing "Toldt's Line" and implication of the left ovary. Obscure left-sided pain and constipation is frequently produced by this condition and relieved by operation. (Modified from Gray and Anderson.)

Assume we approach at birth towards our ancestral condition, and suffer from slight congenital ptosis, or assume that later in life ptosis is produced from similar causes, then there may be peritoneal fusions in unusual places to ensure fixation as a provision of nature against further prolapse.

To revert to the terminal kink of the pelvic colon, which is such a common condition, if we pull on the colon we can see the line of fusion between the outer side of the mesocolon and the peritoneum of the left iliac fossa. This line is known as Toldt's white line.

In cases of chronic constipation, in the absence of other causes, the "undoing" of this kink, especially in enteroptosis cases, will have the effect of producing a regular daily motion, and a consequent great improvement in the condition of this miserable class of patient.

I have operated upon several cases for my colleagues, Drs. Lumsden and Holmes, with the result stated.

Left-sided abdominal pain with constipation may often be completely relieved by a plastic operation on this kink, and it should be remembered that the pain is often rendered more severe by implication of the left ovary and broad ligament in the line of fusion. (Fig. 5.)

The congenital theory is not upset by the contention that symptoms do not arise until adult life. We have only to think of such conditions as cervical rib and congenital hernia to see where the fallacy of such a contention lies. The nature of the operation required in each case is shown in the illustrations and requires no further description.

In two of my cases there were so many developmental adhesions and kinks that I short-circuited the ileum into the lower sigmoid—the operation recommended by Lane. (It is not possible for anatomical reasons to anastomose the ileum with the rectum as frequently stated.)

If the permanent results of the plastic work are as good as the immediate results the short-circuiting operation will become unnecessary, but in any event the operation, as often attributed to Lane, is not performed in the manner he recommends, and gives correspondingly bad results. The ileum must be completely divided and anastomosed low down below the sigmoid kink.

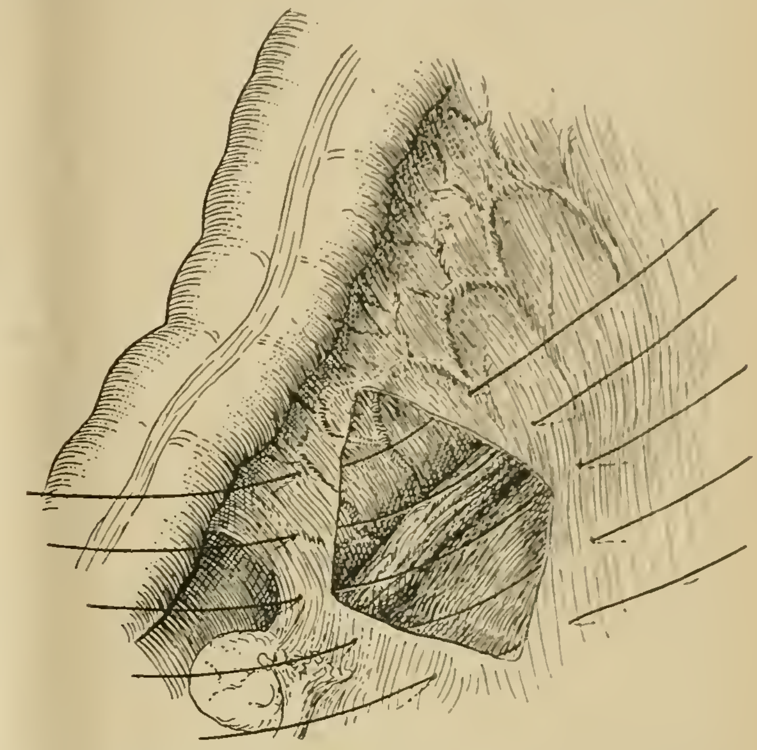

Fig. 5.—Kink of the Pelvic Colon relieved by plastic operation. (Modified from Gray and Anderson.)

If the kink is not well marked it should be artificially produced to prevent reverse peristalsis—a complication which, in early days, rendered necessary a subsequent colectomy in a fairly large proportion of cases.

In my series of cases the symptoms were very varied. Left-sided pain and discomfort by a process of elimination was diagnosed in several cases as being due to a well-developed mesosigmoid kink. These patients, usually females, were cured by operation.

Diffuse right-sided pain, tenderness, and discomfort in patients with a mobile splashing cæcum and distended ascending colon, were found usually to present a well-marked Jackson's membrane and hepatic kink; the appendix often showed little or no signs of disease. The ileal kink was present in some of these cases, but absent in at least an equal number. One case diagnosed as duodenal ulcer proved to be a megaduodenum accompanied by Jackson's membrane and ileal kink. The patient was a medical man, and presented all the signs and symptoms of duodenal ulcer. X-ray photographs supported this view, but on operation only the conditions mentioned were found. The patient was completely and immediately relieved by a plastic operation.

Two cases only were typical of auto-intoxication—there was staining and wrinkling of the skin, sweating in the axillæ and groins, enfeebled circulation with cold extremities, dulling of the mental faculties, etc. The complete short-circuit operation was performed. These patients are tolerably well. One was done two years ago, the other has just left hospital, but still complains of abdominal distress. The number of ailments directly caused by intestinal stasis are probably legion, but of the remote lesions, such as chronic rheumatoid arthritis, cystic breasts, and hypothyroidism I have no personal knowledge, and therefore I only mention them to dismiss the subject.

I am convinced, however, that many cases of rheumatoid arthritis in the early stages can be cured or relieved by the correction of intestinal lesions causing stasis, in a more certain manner than by the administration of intestinal antiseptics and other drugs.

X-ray photographs were taken of a number of the cases by Dr. Hayes to assist localisation of the lesion before operation.

I must acknowledge my great indebtedness to Mr. Gray and Sir Arbuthnot Lane for allowing me to see their operations and results in connection with this subject.

A GUIDING PRINCIPLE IN THERAPEUTICS.

By J. SNOWMAN, M.D., M.R.C.P.LOND.

IN a recent communication (*a*), Dr. William Bain refers to the treatment of gall-stone disease in the following words :—" At the risk of unduly emphasising the point, I would reiterate my belief that the primary and essential factor in the treatment of this affection is the rectification of the digestive functions. By correcting dietetic errors, and stimulating the digestive powers, the nutrition and vitality of the individual are enhanced ; the resistance of the tissues is increased, and as a corollary, the affected organ shares in the general improvement."

This dictum has such wide application in every sphere of medical treatment, and its neglect is responsible for so many therapeutic failures, that it is worth while studying it a little more closely. The exhibition of a drug, without an examination of the general metabolic functions of the body in order to ascertain the prospects of its absorption, is an irrational proceeding and the neglect of the first condition of success. It is only necessary to mention the abundant failures in the treatment of anæmia which follow the orthodox administration of iron—failures which are converted into successes when the powers of assimilation are taken into account, and improved. Or, again, we may refer to the occasional impotence of quinine sulphate to exert its specific effect on malaria, solely because this salt fails to become absorbed. When, however, the easily soluble hydrochloride is substituted for it, the specific action of the quinine takes place without delay.

Unfortunately, there are not many diseases, like malaria, which possess a specific remedy. We are justified in saying that quinine cures malaria, mercury cures syphilis, thyroid extract cures myxœdema. It has been truly said that the greater the abundance of drugs in vogue for any special disease, the greater are the difficulties of treatment. It is notorious that failures most frequently occur in the very cases where the choice of drugs is particularly extensive. For example, rheumatoid arthritis enjoys a little pharmacopœia all of its own, ranging from salicylates and their new derivatives, arsenic, guaiacol, cod-liver oil, iron, iodide of potassium, to all varieties of physical therapeutics. Nevertheless, the disease is characterised by great obstinacy, and often constitutes the despair of the practitioner.

The diseases wherein the greatest successes are scored are, undoubtedly, the specific fevers. But it must be confessed that recovery from pneumonia, typhoid fever, or scarlet fever cannot usually be put to the credit of the drugs which have been employed. The recovery, in these circumstances, is a natural process effected by the normal physiological defences of the body against the invasion of pathogenic organisms. The drugs can do no more than relieve symptoms. The real victory over the disease is achieved by the immunising processes which take place. Rational treatment consists in encouraging and developing these processes. A whole system of therapeutics, which is based upon the production of active immunity is now in the making, and although considerable time must elapse before its precise value in medicine can be determined, it has already become abundantly clear that the first and foremost condition of success in treatment is the efficient working of all the physiological processes within the organism.

Some of the physiological processes are active in a state of health, but others are not evoked until the organism is attacked by disease. These latter, are, however, seriously handicapped and thwarted in their action unless the former are up to the normal standard. If the ordinary physiological processes of the body are defective, the reaction to disease will be indifferent. Drugs will refuse to act, and symptomatic treatment will prove a failure, until it is recognised that it is useless to deal with detailed damage to the structure unless the foundations are made secure.

The foundations of good health are based upon a normal metabolism, and the cardinal principle of success in treatment revolves around this as the central pivot. It is not too much to say that the failure of a curable condition to yield to treatment means a derangement of metabolism, and the practitioner would do well in all such obstinate cases to devote himself to the improvement of metabolism, rather than to ringing the changes upon drugs, or to despairing of effecting a cure.

It is hardly necessary to say that the term " metabolism " conceals no mysteries. Its meaning is simple, its connection with disease is quite definite, and its influence on treatment is beyond all doubt. Briefly put, *metabolism* is the name given to the series of changes which (*a*) begin with the food taken as nourishment and end with its conversion into a tissue cell, and also to the series of changes which (*b*) the cell undergoes during its vital activity, its processes of combustion and its disintegration into normal excretory products. The changes comprised under (*a*) are sometimes called *Anabolism*, those comprised under (*b*), *Katabolism*. Together they constitute Metabolism.

Errors in the process of the building up of cells (Anabolism) or in the process of their breaking down (Katabolism) are among the most fertile causes and consequences of disease. The persistence of these errors, and the neglect to remedy them, are likewise *the great causes of failure in*

(*a*) *The Practitioner*, May, 1913.

treatment. When the fault is along the path which leads to the building up of a tissue cell, we are confronted with some form of indigestion, in its protean varieties, or with a disease of malnutrition, *e.g.*, anæmia, neurasthenia, &c. When the fault is along the path by which normal combustion should proceed, and its products become abnormal, the diseases which result are mainly gout and diabetes. It is not, however, possible to separate all, or even most diseases into an anabolic and katabolic group in this way, because the toxins of so many diseases produce derangements both in the constructive and in the disintegrative processes of metabolism. Thus, tuberculosis, rheumatoid arthritis, the acute specific fevers interfere with assimilation on the one hand, and on the other hand give rise to toxic products of combustion instead of the normal excretory substances. These diseases cause wasting, owing to the inadequate cell formation and the too hurried cell destruction, and in these, convalescence or recovery is marked by an increase in weight.

It is obvious from the foregoing remarks that the restoration of healthy metabolism must be one of the guiding principles in the treatment of disease, and it follows that therapeutic failures must, as a rule, be put to the credit of the neglect of this principle.

Is this principle sufficiently emphasised in orthodox systems of treatment, and does the profession, as a whole, recognise its paramount importance in daily work?

It must be confessed that the general practitioner is only vaguely concerned with the problems of metabolism in his routine work, and that text-books of therapeutics hardly proceed in this direction much beyond a general recommendation, in most diseases of "good food, fresh air and sunlight." It is often pointed out that recovery from disease is encouraged by such improved conditions. A tardy convalescence is hastened by residence at the seaside, and obstinate anæmia begins to improve in the surroundings of a country life, and chronic indigestion will often refuse to yield until the patient has a "thorough change." The true reason that success attends these measures is, that they exercise an effect on metabolism and tend to restore it to the normal, and then the opportunity is afforded, either to nature or to art, to bring about a complete recovery. This endeavour to influence metabolism should therefore accompany the therapeutic measures which may be adopted in any case, and there can be no doubt that if attention to this physiological need became a routine principle in treatment, drugs would achieve more than they do at present.

BREAST FEEDING OF INFANTS. (*a*)

By ELLA G. A. WEBB, M.D.

It appears to be acknowledged in all discussions that the problem of infantile mortality is to a great extent identical with the problem of infant feeding; in other words, that the mortality from gastro-intestinal diseases is so high that if we could discover a universally suitable food substance there would be no infantile mortality problem to discuss. Writers on the subject of feeding generally preface their remarks by emphasising the necessity and importance of breast feeding whenever possible, but after a few general statements on this point, proceed to the discussion of the various kinds of artificial food, their chemical and physical composition, their drawbacks, their modes of preparation and so forth. In fact, we are too ready to say, "This woman cannot nurse her infant, let us seek to discover the best possible substitute on which to feed it"; instead of saying, "This woman cannot nurse her infant, let us seek to discover why, and remedy *that* defect." I am fully aware of the excellent work done on this subject by many members of the American school of pædiatrics, and in England by Vincent and others, but we still remain very ignorant of the forces governing the function of lactation. Why, of two sisters, one can nurse her children and the other cannot? What is the nature of the toxic products let loose in the milk by an ebullition of nervous emotion on the part of the mother? These and many other problems of this kind remain still unanswered; there is not even, so far as I am aware, a comprehensive list of the drugs that are excreted in the mammary secretion, thereby influencing the child.

With a view to gaining some information on the subject, I have for the last three or four years endeavoured to ascertain, in each case of a bottle-fed infant brought to me for treatment, what was the reason that the mother did not nurse it. I propose here, if you will allow me, to submit to you an analysis of 200 such cases. I am fully aware that this number is too small to be of very great value, but I venture to put the cases before you with a brief *résumé* of the measures I have found to be most useful in each class, in the hope that I may learn something from those of wider experience as to fresh lines along which to pursue further investigation.

The analysis of the reasons for giving up nursing in the 200 cases are as follows:—

1.—Insufficient milk	93
2.—Illness of the mother	35
3.—Milk disagreed with child	22
4.—Sore breasts	16
5.—Mother having to go to work ..	13
6.—Advised to wean by nurse or friend ..	8
7.—Child refusing to take breast ..	5
8.—Death of the mother	6
9.—Child having a hare lip	1
10.—Accidental illness of child causing great fatigue to the mother through wakeful nights, etc. ..	1
Total	200

The last three groups require no comment, though it may be said that in the case of the child with the hare lip an endeavour was made for some time to pump off the breast milk and feed it, but the supply gradually diminished.

Classes 6 & 7.—With regard to the refusal of the child to take the breast and the advice of the nurse and friends, I should like to point out that all nursing, particularly in primiparæ, is difficult at the beginning. The recumbent position of the mother, her inexperience and possible awkwardness, the small and undeveloped condition of the nipples, all tend to put difficulties in the way of the already reluctant and worried infant, and we are all familiar with the spectacle of an anxious and perspiring mother clasping to her breast a bawling infant that cannot be persuaded to cease from its protestations sufficiently to close its widely open mouth on the nipple!

I bracket this class of case along with those in which the nurse advises bottle feeding, because there is no doubt that here nothing but great determination and still greater patience on the part of both nurse and mother can win the day, and if either fail, the result is that the baby conquers, and resorts to the easier method of a bottle with a rubber teat containing a large hole! I am sorry to say in most maternity nurses there lurks a desire to bottle-feed the infants in their care. I know it is contrary to all their teaching, and I can give no reason for it. It is often not shown to the doctor, but the desire is there, nevertheless, and until it can be thoroughly uprooted, many babies will be handicapped in the race of life. As far as I can

---

(*a*) A paper read before the Section of Obstetrics, Royal Academy of Medicine in Ireland, May 23rd, 1913.

make out, the reason that some officious friends advise weaning is that the bluish, somewhat translucent appearance which human milk naturally possesses, gives rise to the idea that it is "poor" and of no nutritive value. The best remedy for these errors, I think, is wider instruction of nurses on the nature and normal appearance of human milk and also on the intelligent and more frequent use of the nipple shield to assist the child in its early efforts.

With regard to class 5, viz., industrial occupation of the mother, it strikes one at once how very low the percentage of cases in Dublin is (viz., 6.5 per cent.) compared to manufacturing towns, but even here the establishment of well-managed crêches, in various parts of the city, open from 6 a.m., would greatly facilitate the mother returning to nurse her child at different times in the day.

Class 2—"Illness of mother" may be passed over without comment except to note that about one-sixth of the total cases were of pulmonary tuberculosis.

Class 4—"Sore breasts" (8 per cent.).—Under this heading I include both breast abscesses and also minor troubles such as cracked nipples, etc., which by the pain they cause deter the mother from nursing. Measures to avoid weaning fall under three headings, viz. :—

(1) Preparation of the breasts.
(2) Prevention of infection during lactation.
(3) Intelligent use of the breast pump and nipple shield in cases where the breast has already become sore.

Very few women of the poorer class make any effort during pregnancy to prepare their breasts for nursing, and among those that do, the method employed is inadequate, consisting simply of occasionally rubbing the nipple with some form of alcohol and pulling it slightly with the fingers. The result of this treatment is frequently to cause the cracks and abrasions the women are trying to avoid. I have found that the constant use of alcohol alone renders the skin much too dry. To prevent this, after the alcohol has evaporated some boracic ointment should be used while the drawing out of the nipple is performed. I should like also to point out that manipulation with the fingers is not—and never can be, sufficient preparation for the virgin nipple. The pain in early lactation is caused by the forcible *eversion* of the partially *inverted* tip of the nipple, and pulling it with the fingers cannot help. It is best effected by gentle suction when the part is pliable with ointment. This suction can be effected either by a breast pump, a tetarelle, or by a cheaper instrument, namely, an ordinary new clean clay pipe which after being boiled and smeared with boracic ointment is used with the bowl over the nipple and the stem in the woman's mouth.

The prevention of infection, when lactation is established, is the next problem. It may take place along the tubules without any visible crack or abrasion, and I have found that washing after each feed even if dutifully performed is of little use, as some milk always oozes on to the surface and clothes immediately afterwards. The most efficacious plan I know of is to instruct the mother always to wear a small pad of boracic wool over the nipple, protecting it from the clothes, and I have never known any infection to occur when this was constantly done, even in cases formerly much troubled with incipient abscesses.

If pain and redness do appear, fomentations are of great service, but I have found far better results from the use of large pads of wool, soaked in pure glycerine applied hot, or in the more elegant form of the same drug, known as "antiphlogistine." This if applied in time nearly always averts the dreaded suppuration. In any painful condition of the nipple a shield should be used, and nursing can often successfully be performed by its help under most unfavourable conditions.

Classes 1 and 3 (*i.e.*, insufficient milk and milk disagreeing with the child) may be taken together as cases where the child does not thrive on the milk, but for purposes of scientific investigation they may be divided, not according to the statement of the mother but into 4 groups, viz. :—

(*a*) Insufficiency in the quantity of milk.
(*b*) Insufficiency of some particular element.
(*c*) Undue preponderance of some element causing disagreement with the child.
(*d*) Presence of toxic substances.

It is on the correct diagnosis of the reason why the milk disagrees that the only hope of remedy depends.

At the beginning of my investigations I naturally tried to find what substances were supposed to lead to increased milk production in cows. Knowing the great difference in percentage composition of human milk that may be caused by change of diet, I was greatly surprised to find that apparently most authorities agree that change of "rations" makes very little change in quantity or quality of cows' milk, compared with the value of breeding and favourable nervous conditions. There seems to be no doubt, however, that in the case of human beings, variations can easily be caused in total quantity, in proteids, and in fats. Lactose seems to remain fairly constant in amount.

With regard to quantity—some women seem to have suitable milk ; only that, in the case of a big hungry child, or with twins, there is not enough of it. These cases are undoubtedly helped by the ingestion of large quantities of fluid. Soup, gruel and even plain water should be taken in large quantities. Most women, as a rule, take too little fluid, and this point should be emphasised. The urine is, of course, thereby increased, but that does not alter the fact that the milk is increased also. Violent exercise, causing much perspiration, should be avoided, as well as nervous fatigue. Gentle and careful massage of the breasts is of use, and the child should be given both breasts at each nursing in order to stimulate them.

Alcohol undoubtedly increases the quantity of milk, but is unadvisable for many reasons. The chief one that concerns us at present is that it frequently upsets the child's digestion. Malt increases the quantity of milk as well as the fat present. If ordinary malt extract is disliked, malt can be given in a variety of other ways, such as malted cocoa, malted milk, and by means of preparations such as Mellin's Food, Ovaltine, etc.

I must also mention a preparation which, although I was familiar with it abroad some time ago, has only recently been introduced into this country. It is called "Lactagol," and its manufacturers state that it is a preparation of cotton seed, its galactogenic properties being due to a substance named "Edestin" which it contains. The constitution and action of "Edestin" have been investigated by Beckman of Hamburg, who states that in his opinion, the *quantity* of proteid in various foods cannot have a decisive influence on the galactogenic action, but, on the other hand, the *composition of the proteid body* seems to play a *rôle*, for we see that the amides, the splitting up products of the proteids in malt grains, have a similar action to that of the edesten of the cotton seed meal.

He adds : "Edestin received its name from Osborne, who studied it closely. It has also been put to practical use by Zadik and Hausmann. It contains 42.3 per cent. of the total nitrogen of the cotton seed meal, and is constituted as follows :—

Carbon	51.71
Hydrogen	6.86
Nitrogen	18.64
Sulphur	0.62
Oxygen	22.17

"The phytovitellines to which edestin belongs are characterised by a high nitrogen value and a low oxygen value. On splitting up they produce a large quantity of diamin acids, that is to say, products such as arise in the changing of the proteins in growing plants.

"If the galactogenic action of the malt grains is to be referred, as suggested by Maercker, to the amides then the galactogenic action of lactagol is explained, for the tryptic digestion of edestin furnishes the same bodies as are brought into existence in malt grains through enzymes, which act in the plant cells."

The results of the quantitative hydrolyses of "Edestin" recently published, which were carried out by Aberhalden under the direction of Emil Fischer, give an indication of the cause of the specific action—namely, a very large proportion of argenin over the other two products of splitting the proteins, *i.e.*, lysin and histidine.

Beckman used "lactagol" as the substance with which to conduct his experiments, and got favourable results both in cows and women. With the former he got a rise in the fats of from 3 to 3.9. In the proteins of from 3.2 to 3.7, and in the total amount of milk a rise of from 13 to 17 litres per day. I cannot quite reconcile these results with the statements of Kelner and Jordan, but with regard to human milk secretion I can heartily endorse them. I have always found a rise of at least two or three points in both fats and proteids, as well as a great increase in the total quantity of milk. I also used the preparation in twenty cases in which the infants' weights were stationary or diminishing, chiefly through malnutrition from extreme poverty in the mother, and got a rise in weight of from 3 to 6 oz. per week in all but one case. (I may add that I consider this a better test than any rise in percentage composition.) The only disadvantage I have found from the use of this substance is that it occasionally causes indigestion in the baby by raising the proteids too high. For this reason I usually give less than the prescribed amount, and watch the cases carefully at first.

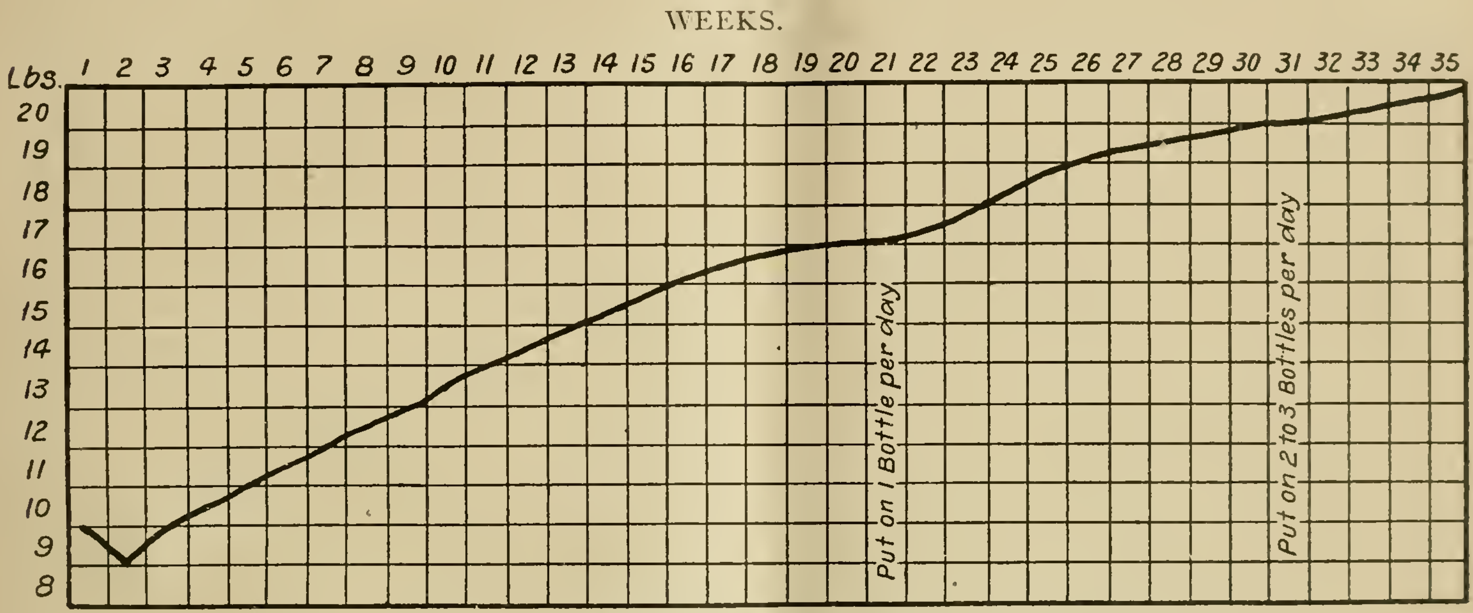

Fig. 1.—Showing rise in weight on the addition of one bottle each day.

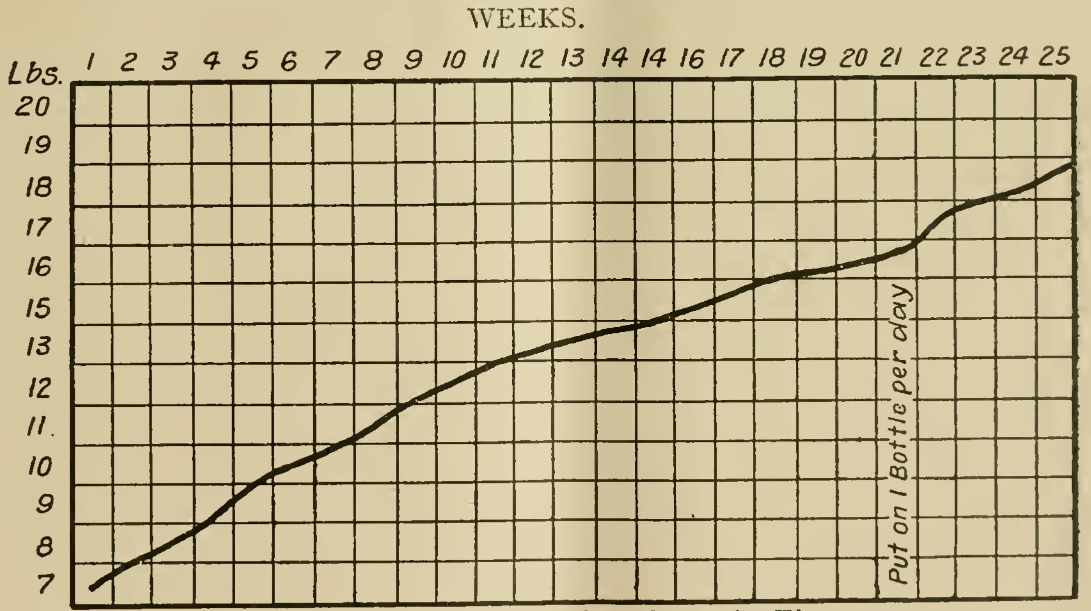

Fig. 2.—A similar case to that shown in Fig. 1.

If it is found to be impossible to obtain a sufficient quantity of milk for the requirements of the child, I strongly advocate mixed feeding (that is to say, the giving of one or more bottles in the day) rather than weaning. I know, in giving this opinion, I am going against that of so great an authority as Vincent, but I do so for the following reasons:—

(1st) The extremely good results I have always obtained by it. The accompanying charts are two taken from many indicating the success of this method. (Figs 1 and 2.)

(2nd) That weaning is thereby rendered much easier on both mother and child, because it is gradual.

(3rd) Because in cases of long journeys, accidents to milk supply, illness, etc., there is always the breast to fall back upon temporarily.

The difficulty of knowing the strength of milk to give from the bottle can be overcome by an occasional analysis of the breast milk.

Next, with regard to lack of some particular element. The average composition of human milk is :—

Proteins	1.5 per cent.
Fats	4 ,,
Lactose	7 ,,

The element which most frequently falls below the standard is fat. It can be increased, however, by a good nourishing dietary—particularly one that is rich in protein—by the administration of malt extract (according to Holt this last can raise the fat percentage from 1.74 per cent. to 3.83 per cent.) and by the aforementioned lactagol.

Also, if the supply of milk is abundant, but the fat low, the child can be fed on the latter part of the milk from each breast, the "fore milk," which is high in proteins and low in fat, being drawn off with a breast pump.

The proteins generally give trouble by being too high rather than too low. They are generally supposed to be increased by over-feeding and lack of exercise, and can be diminished by regulating the diet and getting the mother to take long walks, to scrub her floor, or take some other form of active exertion. Vincent quotes two cases, however, in which the proteins were raised over 3 per cent. by reason of the mothers leading *too* active lives, going too much into society and being over-excited. The infants, who were both upset, recovered when a quiet life was again enforced.

Undue amount of protein is generally recognised by indigestion and the passage of undigested curds in the motions. It must be remembered, however, that all that a mother calls curds are not necessarily protein. Fat " curds " are very common, but are easily distinguished by the ether test.

Cases where the fat is too great in amount are usually recognised by undue looseness of the bowels on the part of the infant. This may be regulated by giving less protein in the mother's diet and by not letting the infant empty the breast, as the last part is particularly rich in fat.

Infants seem to vary very much as to their tolerance of extraneous substances excreted in the milk. The diet of the mother as regards fruit and vegetables should, at first, however, always be tentative. Three articles of food I have found nearly always to be injurious, viz. :—Cabbage, onions, and rhubarb. They are therefore better left alone. It is nearly always the case when the mother eats much vegetables or fruit that the infant's motion become green. Too much importance need not be laid on this, however, if it is unaccompanied by any symptom of discomfort and if the increase in weight is constant.

A difficulty frequently arises when the mother requires laxative medicine and the infant does not; the only purgative I know that does not affect the milk is castor oil, and its continual administration is generally objected to by even the most self-sacrificing of mothers! A good deal may be done, however, to stimulate the mother's peristalsis by substances containing some indigestible residue, *i.e.*, porridge, Frame food, etc., by petroleum emulsion in some form, and by massage.

Much more serious are the toxic products which appear in the milk as the result of mental excitement and worry. In this particular the resemblance to cows is much greater than as regards food. Kelner and Jordan both agree in ranking " the feeling of comfort and well being " as foremost in importance from the point of milk supply, while " anything that upsets a cow " is considered to have a worse effect than bad feeding. Vincent quotes the case of a cow whose fats dropped from 3.6 to 1.8 in the show yard. It should be noted that it is *worry* and not *work* that causes these bad results. I know many women who do an extremely hard day's work—either mental or physical—who still nurse with ease and success. Holt says: " It is the nervous condition of the mother more than anything else which determines her success or failure as a nurse," and I am sure all who have had experience of cases of this kind must agree with him. It is here that the physician feels most helpless, for although it might seem natural that a mother would consider her child's health of greater importance than the polish of her brasses or the deportment of her servant, such is not always the case, and in spite of warnings, constant worry over unimportant trifles defeats all the doctor's efforts, and at last necessitates the substitution of artificial food.

One reason for abandoning nursing I have not put on my list because it was never given me in so many words—that is, unwillingness on the part of the mother. I do not doubt, however, that it was the true cause in a few cases, and as such we ought to bear it in mind. I do not think that any good mother who had experienced the comfort, convenience, and economy of nursing, as compared to bottle-feeding, would willingly depart from it, but young primiparæ are sometimes unwilling to undertake the task. Here the medical and nursing professions can do much in the way of instruction and preparation, by showing the young mother that nursing is healthy for her as well as her child, and is very far from being the strain and the bondage that her friends would have her believe.

This brings me to the most important part of the whole question. So far I have only suggested remedial measures to be undertaken at the time. In reality we should begin to prepare our ideal nursing mother long before she herself is born! We are still much in the dark as to what promotes or hinders the possibility of lactation, but it is generally acknowledged that it is artificiality and civilisation rather than poverty or starvation that render the numbers of nursing mothers so low. Crookshank, in a recent article in the *British Journal of Children's Diseases* lays stress on what he calls the biological value of food. He says: " The wife of a cottager is better fed biologically on wholemeal bread, even though black; on fresh milk, even if skimmed; on home-made cheese, even though sour, and on oatmeal, even if savoured with salt only; than is her town-dwelling sister on frozen mutton, tinned tomatoes, condensed milk, and packet tea."

How much the diet may affect the possibilities of the child that is to be born, has, of course, still to be investigated, but we may fairly consider that the eugenist's plea for more simplicity and less artificiality of life may be put forward also by the doctor interested only in the problem of the nutrition of the child.

Another question which has not yet been answered is how far the mother's diet during pregnancy affects her powers of lactation subsequently. So far as I can ascertain, most women who have been on a carbohydrate diet for fear of eclamptic complications have been unable to nurse their infants, but I should like very much to hear the experience of others on this point. The theory is rather contradicted on the other hand by the fact that the poor woman whose diet is often nothing more than bread and tea makes an excellent nurse. In fact, it is often to me a matter for wonder how well the very poor do nurse their infants. It certainly tends to show that a careless happy-go-lucky frame of mind (for I have never seen a tenement house dweller give her infant indigestion by fretting over the dirt of the stairs) may achieve a result which hard work and lack of food cannot counteract.

In conclusion, I may, perhaps, be permitted to add a few hints as to the clinical examination of milk. While there is no doubt that a complete chemical estimation is best, and is frequently necessary, still there are various rough methods of gaining some knowledge of its composition.

(1) Colour.—To those who accustom themselves to looking at samples of human milk, the rich cream colour due to high fats or colostrum is at once apparent.

(2) In ordinary cases the first half-ounce or so that flows it almost clear. If this is white and milky, the fat is usually high.

(3) By means of Holt's cream gauge the gravity cream can be read off after standing for 24 hours. The percentage of fats can thence be calculated, as it is in proportion to the cream as 3 to 5.

(4) A rough guide to the proteins may be obtained by knowing the fats and the specific gravity. The normal specific gravity is 1030, and if the specific gravity is high, while the fats are normal, the proteins are probably high also, as, of course, proteins raise the specific gravity while fat lowers it.

The milk for analysis should always be taken from a mixture of the whole contents of the breast.

The quantity of milk obtainable can best be ascertained by weighing the infant before and after feeding.

Finally, I should like to add that I am fully aware of the shortcomings of these investigations, and can only say that I have mentioned nothing that I have not ascertained by careful personal observation and experiment, and only because of this can this paper claim any merit. It is written in the hope that others may be led to make further investigations on their own cases, which will lead to more extensive results, and bring about the improvement in this matter which is so badly needed at the present day.

OPERATING THEATRES.

LONDON HOSPITAL.

Gastro-jejunostomy.—Mr. James Sherren performed posterior gastro-jejunostomy on a patient 15 months ago. She then had a large saddle-shaped ulcer situated on the middle of the lesser curvature, the posterior portion of the ulcer involving the pancreas. A portion was removed for microscopical examination; it showed no evidence whatever of malignancy. She had been suffering off and on from "indigestion" for four years, having had typical attacks of severe pain after food, accompanied by occasional vomiting, which relieved it. During the last two attacks she had hæmatemesis. After the operation she remained perfectly well for twelve months; her old symptoms then returned.

Mr. Sherren remarked: What we have to consider is the condition underlying the return of symptoms. Chronic gastric ulcer, wherever situated, heals after gastro-jejunostomy, and the patient remains perfectly well in over 80 per cent. of the cases, almost well in another 16 per cent., relapse in about 3 per cent. There are two possible explanations—(1) that the ulcer has not healed; (2) that a jejunal ulcer has formed. We shall probably find the former; the position and character of the pain is unlike that in jejunal ulcer following gastro-jejunostomy. This patient has most of her pain at night, and it is situated in the epigastric region. In chronic jejunal ulcer pain comes on regularly after a meal, is usually felt in the region of the umbilicus or just to the left of it, and is often relieved by taking food. Another point telling against jejunal ulcer is the fact that acidity, both free and total, remains low as the result of her operation.

The abdomen was opened through the right rectus muscle; the abdominal cavity was found free from adhesions; the gastro-jejunostomy was perfect. The anterior part of the ulcer and that on the lesser curvature had completely healed, but the posterior portion of the ulcer remained eroding the pancreas.

Mr. Sherren proceeded to do a partial gastrectomy, dividing the stomach at its pyloric end between clamps, and closing the pyloric end with a through-and-through continuous stitch of chromic catgut, buried by a similar one of 00 silk. The stomach was then separated from the pancreas, and it was found that the floor of the ulcer was formed entirely of this viscus. The ulcer and the neighbouring portion of the stomach were removed, and the wound in the stomach sutured in a similar manner to that at the pyloric end. A gauze drain was carried down to the bare area on the pancreas and the abdominal wound closed in layers The gauze was removed at the end of 48 hours. Microscopical section showed the condition to be a simple ulcer, and the patient left hospital for a convalescent home 17 days after her operation.

Mr. Sherren remarked that this patient bore out his recent experience that posterior gastric ulcers adherent to the pancreas, particularly those in which perforation had taken place and the floor was formed of pancreas, rarely healed as the result of gastro-jejunostomy. This case was particularly instructive in that a large portion of the ulcer situated on the anterior surface of the stomach and on the lesser curvature had healed completely, leaving only that portion which was adherent behind.

The surgical treatment of chronic gastric ulcer consists in gastro-jejunostomy combined with infolding or excision of the ulcer if this is situated on the lesser curvature, although Mr. Sherren does not look upon this as essential; he does it as an additional safeguard. When the ulcer is posterior and adherent it should always be excised. In many cases this can only be satisfactorily done by the trans-gastric method, in these gastro-jejunostomy is not always carried out; but in every case other abdominal lesions, such as gall-stones and chronic disease of the appendix, should be looked for.

It may have been noticed that the present patient has a scar in her right iliac fossa. Mr. Sherren removed her appendix through a separate incision, as has been his custom for several years. It was, as usual, of the fibrotic type, and was kinked into C-shape by an adhesion running from its tip to the cæcum.

Treated on these lines, Mr. Sherren is of opinion that even better results than those he has given will be obtained in the surgical treatment of chronic gastric ulcer.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Obstetrics.

Meeting held Friday, May 23rd, 1913.

The President, Dr. A. J. Horne, F.R.C.P.I., in the Chair.

SOME SEQUELÆ OF LABOUR.

Dr. Bethel Solomons read a paper on the above, in which he submitted the results of examining 543 primiparæ on the sixteenth day of the puerperium.

The President said the paper opened up a new field, and obstetricians should insist on the thorough examination of their patients before discharging them. He was astonished at the very high percentage—*i.e.*, 48—of lacerations of the cervix uteri which were found to have occurred in primiparæ, but, of course, the lacerations varied from one-third to an inch. He considered that if that large number of lacerations of the cervix occurred one would expect severe *post partum* hæmorrhage, and it should cause the obstetrician to try to find the origin of the hæmorrhage, and he would deem it a duty to stitch the cervix immediately. He thought that most of the backward displacements he frequently found were congenital and unimportant, and no matter what treatment might be carried out, at the end of two months, if the patient was again examined, the displacement would be found to have recurred. He suggested that if the patient was examined two months after confinement it could be ascertained if there was any real displacement, and an opinion could then be formed as to the treatment necessary. He looked on it as a duty to suture a ruptured perineum at once. Catgut sutures very often became absorbed too soon, and in his practice he invariably used the ordinary silk-worm gut, and found it successful. He had not yet adopted early rising, and from what he had heard he would be chary in doing so.

Dr. Hastings Tweedy said that Dr. Solomons' statistics of lacerated cervices would come as a surprise to many. It had been asserted by an eminent Fellow of the Academy that such tears did not occur in normal delivery. This view was in the main true, but was subject to exceptions, for he (Dr. Tweedy) had reported tears after perfectly normal child-birth. Posture had no effect in bringing about a condition of retro-displacement, which owed its origin to the presence of a full bladder or to congenital defect in the majority of cases. An improperly applied binder was another direct cause, and one that was seldom appreciated. Before the application of a binder the uterus should be sharply anteflexed, and the third pin should be placed so as to groove the binder above the uterus and fix the latter in a condition of anteflexion. Pulmonary embolus was a septic condition, and did not arise in consequence of getting the patient up too soon. It was, moreover, associated, in his experience, with a quick pulse. He had no faith in the power of calcium lactate to stay the progress of a septic clot.

Prof. Thompson said that he did not consider that calcium salts administered by the mouth or hypodermically had the effect of hastening coagulation.

Dr. Spencer Sheill said he had seen many backward displacements of the uterus produced by tight lacing of the corset before complete involution had taken place. The maximum coagulation resulted from calcium salts if administered at broken periods.

Dr. Allan said he had never found calcium salts of much use in helping coagulation. He had found that in suturing the perineum catgut alone did not give as good results as silk-worm gut, or a combination of both. He inquired if the time at which the suturing was done had not an effect on the morbidity. While one did not like putting forceps on the undilated os, he pointed out that Dr. Johnston stated that he had proved that he could do so without any evil effect.

Dr. Solomons, in reply, said that his experience of the calcium salts only extended to cases of threatened abortion, miscarriage, or premature labour, in which he had found them of very little influence. He was unable to say whether perineums united better when stitched immediately or some hours after labour. He was convinced that when forceps were applied to a cervix which was not fully dilated a tear always resulted. He agreed that 48 per cent. of tears in his series was greater than the ultimate results would have shown, but the paper was based on examinations made sixteen days after confinement, and he felt sure that a great number of the tears then apparent would afterwards heal. He considered that a capable nurse could apply a binder better than a doctor, who got much less practice. He thought that although the constant dorsal decubitus was the most common cause of *post partum* retroversion, he did not exclude insufficient emptying of the bladder and other conditions as possible predisponents.

BREAST-FEEDING OF INFANTS.

Dr. Webb read a paper on "Breast-feeding of Infants," which will be found under the heading of "Original Papers," on page 13.

Prof. Thompson said the consideration of the physiological aspect of the question was difficult as so little was known about the physiological stimuli that promoted the secretion of milk. He referred to a paper by Dr. Janet Lane-Claypon, recently reviewed in the *British Medical Journal*, on "The Investigation of the Question of Milk and Lactation." No one had yet succeeded in discovering a nerve, the cutting or excitation of which interfered in the slightest with the secretion of milk. The general opinion was that if the mother was getting sufficient ordinary food she produced as much milk as she would on any special food. He was not a very strong believer in the influence of proteins in increasing the constituents of milk. The only constituent of milk that could with certainty be influenced by the diet was the fat. It was quite possible that milk as regards proteins might become undesirable from an alteration in the relative amount of caseinogen. The practical points brought out in the paper struck him as very useful.

Dr. Hastings Tweedy said mothers and nurses were very fearful of starving the infant. He had observed that breast milk became, as a rule, very scanty on or about the sixth or seventh day, and it was at this time bottles were usually begun. The introduction of bottle-feeding forty-five years ago constituted the most disastrous experiment that the human race ever embarked on. Its condemnation did not entirely rest on the high rate of infantile mortality; more serious still were the ill consequences in after-life inflicted on the infant who worried through a succession of stomachic disorders, or other debilitating illnesses. He could declare, from observations made in his own practice, that bad teeth in the adult seldom occurred in those whose infancy and young childhood had been free from disease. It was evident, too, that permanent defect could not be limited to the teeth. Bones, muscles, brain, skin, etc., must also suffer. Children could deal with excess of some particular constituent in food; this was shown by the splendid results obtained in the whole-milk method of feeding. He did not think that infants should be placed on measured amounts of food. Let them be given what they could digest, at intervals not shorter than three hours. If they threw up, regurgitated, or got diarrhœa of the kind which immediately followed on ingestion of food, urgent indications were thereby afforded that a smaller quantity should be given. More infants were injured by excess than by deficiency.

The President said it was the experience in maternity hospitals that a very large majority of women did nurse, and he believed the mothers amongst the poor were able to nurse for a very long time. Food, undoubtedly, seemed to militate against the secretion of milk or the reverse. He recalled his experience when wet nursing was in vogue—*i.e.*, that over-feeding was one of the chief means of insufficiency of milk. He agreed with Dr. Webb with regard to the application of alcohol to the nipples in preparation for nursing, and also as regarded the pulling out with the fingers instead of with a breast-pump or other such instrument.

THE NEW LONDON DERMATOLOGICAL SOCIETY.

Meeting held Thursday, June 12th, 1913.

The President, Dr. David Walsh, in the Chair.

Dr. H. Samuel showed (1) a young man with granuloma annulare. The lesions were irregularly nodular and circinate, and were distributed upon the dorsum of the hands and neighbourhood of the knuckles. One had been excised and examined microscopically, and this had given the appearances usually seen in granuloma annulare.

Dr. Alfred Eddowes inquired as to the real origin of the condition, whether around the vessels or in vicinity of the follicles.

Dr. Norman Meachen referred to the exhaustive monograph by Dr. Graham Little upon the disease (*Brit. Journ. Derm.*, vol. xx., p. 213). He was struck by the multiplicity of the lesions, as the cases he had previously seen were unilateral.

Dr. P. S. Abraham thought that some of the lesions were umbilicated. He was not at all sure of the diagnosis at the present stage, and he suggested a careful examination of a scraping.

(2) A young woman with erythema multiforme. The lesions would last about six weeks, and at the time of the meeting a raised patch was present upon the ulnar side of the left wrist. The dentition was very bad.

(3) A case of pityriasis rosea in a little girl, æt. 11, showing the typical herald patch upon the trunk. The exhibitor wished especially to call attention to the association of seborrhœa capitis with pityriasis rosea which existed in the present case. He thought that the majority of cases of this affection presented a pityriasis capitis at the same time.

The President thought that the disease was definitely self-limited, and that it was not necessarily accompanied by pityriasis capitis.

Dr. Meachen remarked that the two affections were absolutely independent. He considered that in pityriasis rosea of Gibert we possessed a valuable factor in diagnosis which was not always a true guide in skin diseases—namely, colour, which was quite characteristic of the condition.

Dr. Eddowes thought that it would be a good thing to determine the presence or otherwise of the bottle bacillus of seborrhœa in the lesions.

The President showed a vertical section of the skin from a case of alopecia areata in a woman, showing micrococci lying in the lymph spaces, thus confirming Robinson's observations. The patient also had a slight degree of exophthalmic goitre.

Dr. Dennis Vinrace showed (1) a case of multiple sarcoma of the skin ("tomato growths") in a man, æt. 65, a clerk. His mother was said to have had a similar lump over her collar bone, and she lived to be 82. His father died six years ago at the age of 84. The patient stated that the first lump, about the size of a hen's egg, appeared about twenty years ago upon the left clavicular region. This was painless, but other similar tumours appeared about five years ago, and the last one was the largest and most painful. The tumours were reddish, fleshy and sessile. He had had no treatment. A coloured drawing of a similar condition was also shown from *Nosologie*

Naturelle, Tome I., 1817, Paris, p. 548, by Alibert, under the description of "Cancer globuleux."

Dr. G. W. Sequeira agreed with the diagnosis of sarcoma. He considered that the history corresponded to the cases described, and he referred to a case under his own care in which the growths were upon the abdomen. He thought that radical treatment often did more harm than good, whereas the injection of arsenic hypodermically was sometimes beneficial.

Dr. C. G. Mack referred to a case of sarcoma of the skin occurring in an elderly female, commencing behind the ear. Other growths rapidly appeared in various parts of the body. Some were excised. After the last excision it was noticed that the remainder did not grow more rapidly—in fact, the patient died of another disease.

Dr. Samuel did not see why surgical means should not prove successful if the growth were primary.

The President thought that the growth was free, not involving the deeper structures He suggested the use of Coley's fluid and free excision.

Dr. Abraham felt inclined to try an injection of salvarsan to begin with, also to make a clean sweep of the growth, and then he would commence a course of X-rays.

(2) A woman, æt. 45, with lupus erythematosus of the scalp of eight years' duration. The hair had fallen rapidly since last December. Liquid paraffin had been used in the treatment. A little atrophy was also seen along the margins of the ears.

Dr. Meachen said that were it not for the fact that in the present case there were evidences of slight disease affecting other parts, it would be almost unique, for ulerythema of the scalp alone was very rare. It was by no means uncommon to find the disease associated with tuberculosis, and he instanced a case shown by him some years ago at the Dermatological Section of the Royal Society of Medicine of a woman who had lost eight children with varying manifestations of tuberculosis, she herself suffering from ulerythema of the scalp.

The President remarked that a good many cases of lupus erythematosus gave a positive von Pirquet reaction. He would be inclined to give tuberculin, or at any rate a test injection.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, June 28th, 1913.

At the Fifteenth Meeting of the German Society for Gynæcology one of the principal themes of the Congress was the

Relation between Diseases of the Heart and Kidneys and Pregnancy, Labour and Childbed.

The subject was introduced by Hrn. Fromme, Berlin. The doctrine of hypertrophy of the heart during pregnancy could not be maintained, but there was a strengthening of it during that period. There were cardiac complications in about 20 per cent. of the cases in pregnancy. Of 300 women with disease of the heart during pregnancy 3 died during the pregnancy, or the labour, or the puerperium. Eighty per cent. of the cases had no heart trouble—*i.e.*, no symptoms—during these periods. In from 5 to 9 per cent. there was premature labour, in from 4 to 8 per cent. abortion. The condition of the muscles of the heart was the decisive factor. Women with myocarditis were especially in danger. Women who showed no symptoms on the part of the heart at these periods were not in need of any treatment; dietetic measures were all that was needed. In cases of slight disturbance, medicinal treatment was called for in every case in the first instance, also in greater disturbances in primiparæ, who suffered with heart disease, before the pregnancy set in, and there had been no compensation and in multiparæ in whom the previous labours had been normal, and there was no higher degree of disease of the heart muscles. If medicinal treatment was not responded to at once, interruption of the pregnancy was proper at any time, and also when symptoms of decompensation came on at intervals. Termination of the pregnancy should not be delayed too long in cases where, before the pregnancy, there were compensatory disturbances, or where there had been serious cardiac troubles in the previous confinement. Where compensatory disturbances appeared during the labour it should be terminated manually by operative extraction of the child. Young girls who before marriage showed serious compensatory disturbances should be very earnestly advised not to marry.

Hr. Heu discussed the treatment in the cases alluded to by the first speaker. In any case of the complication of pregnancy plus cardiac disease that required treatment at all, such treatment should be adequate. It consisted in a suitable digitalisation of the heart. For the treatment of all serious cases of decompensation the endovenous treatment by strophanthus of Fraenkel was for the present the best. Interruption of the pregnancy under any circumstances should be deprecated until a trial had been made of the treatment mentioned; and under the condition that the patient should submit to be made sterile. Women with plain indications of a tendency to failure of compensation should not be allowed to marry. With signs of insufficiency in the early stages of pregnancy the uterus should be emptied with as little disturbance as possible. The surgical means of inducing labour should be made use of as little as possible, as the sudden shutting off of a circulation was a dangerous proceeding. Narcosis by inhalation in heart cases was a grave matter.

Hr. Jaschke treated of kidney disease in diseases of the heart in women who were pregnant. Normal pregnancy as well as all diseases of the kidneys called for extra efforts on the power of the heart. But the quickly changing calls during labour were of the greatest importance. Although simple valvular disease in pregnancy was not of grave prognosis and irreparable failure was met with in only from one-half to one per cent., the prospects were much more clouded when to this was added a hypertonic disease of the kidneys. When these complications were met with in any case delays must be avoided, the uterus should be emptied at once.

Hr. Kreiss, Dresden, discussed disease of the heart in pregnancy. In 23,577 labours, including abortions in the Dresden Klinik between the years 1903 and 1912, the pregnancy was brought to an end manually 26 times on account of excessive decompensation in disease of the heart. Amongst these there were 16 cases of mitral disease, three affections of the aorta, seven of disease of the cardiac muscle. Of these 26 patients four only died, taking away two that died of sepsis, or only 7.5 per cent. As regarded the question of the interruption of the pregnancy they took the following conservative position:—First, attempts were made to correct the decomposition by medicinal measures. If these failed recourse was at once had to artificial termination of the pregnancy. On the ground of their own experience manual measures were taken in hand without a previous trial of medicines in congenital stenosis, in pericarditis with exudations, in recent endocarditis with pronounced insufficiency, in kyphoscoliosis as well as in cases in which the heart mischief was associated with tuberculosis, nephritis, pernicious anæmia, and enlarged thyroid. Such complications were met with in 50 per cent. of all the cases, nephritis in 34.6 per cent. If the child was believed to be viable either the vaginal or the classical Cæsarean section was resorted to; the first, however, they declined when the symptoms of stagnation of the circulation were prominent, recourse was then had to the classical operation, and if possible under lumbar anæsthesia. In a few serious cases they employed metreurysis (14 time in the 26 cases); atonic flooding was met with in three cases. As regarded the 16 viable infants four died, equal to a mortality of 30 per cent.

AUSTRIA.

Vienna, June 28th, 1913.

SPLENECTOMY FOR PERNICIOUS ANÆMIA.

AT the recent meeting of the K.K. Gesellschaft, Dr. A. von Decastello exhibited a patient, æt. 52, on whom the operation of splenectomy had been performed for pernicious anæmia. In October of 1912 a sudden attack of fever set in, which was accompanied by acute cervical pains and great lassitude. After a few days the skin became markedly tinged with a golden yellow. In December following the patient presented a typical picture of advanced anæmia, accompanied by distinct icteric tinging of the skin and sclerotic. There was also œdema of both legs, and retro-ocular hæmorrhages had taken place. The spleen extended beyond the costal margin to the extent of two fingers' breadth, in the form of a solid tumour. The liver was also easily felt and dense, with a sharply defined margin. The urine was dark in colour; it presented no biliary colouring matter, although there was a great deal of urobilin. The alvine evacuations were deeply stained. Examination of the blood gave:—Erythrocytes, 1,236,000; hæmoglobin, 29 per cent.; colour index, 1.2; leucocytes, 2,600; with 43 per cent. lymphocytes. Among the erythrocytes were abundant macrocytes and gigantocytes, with intensely basophile coloured cells; Jolly's corpuscles and Schleip's rings, and spot formation were also observable throughout. Among the leucocytes, the pronounced polymorphism of the neutrophiles was conspicuous. Blutplättchen were few in proportion. Gastric achylia completed the typical picture of pernicious anæmia. The usual therapeutic procedures were adopted, without any favourable result; the general condition grew worse, with extreme œdema of the legs, and ascites, somnolence, and a fall of the erythrocyte count to 750,000. In this state of apparently hopeless prognostic outlook Finsterer carried out the splenectomy on March 20th. The operaton was followed by rapid improvement of all the symptoms. The icterus had completely disappeared within ten days, the urine became pale and copious, the œdematous fluid was reabsorbed, and at the end of five weeks after the operation the patient was able to go about again. There was a profusion of supply of new normoblasts, displaying an active erythropoiesis; and this progress continued with but slight oscillations, till at the end of eleven weeks the condition of the blood had nearly reached the normal standard. It was, on May 29th: Erythrocytes, 4,052,000; hæmoglobin, 83 per cent.; colour index, 1. At the same time the number of abnormally large erythrocytes had conspicuously diminished; while the cells presenting a granulo-filamentous structure are only found singly here and there. The leucocyte-forming function of the bone marrow received a stimulating stroke, as it were, by the removal of the spleen, which seemed to arouse it from a torpor, with the result that the persistent leucopenia which had previously existed was transmuted, under the influence of bronchitis and decubitus, into a hyperleucocytosis (15,000 leucocytes). The proportion of blutplättchen has simultaneously risen to a standard far above the normal. The gastric achylia has remained unchanged up to the present; nevertheless the nutritive processes are unimpaired, the increase of weight has already reached several kilogrammes, and the general prospect of the convalescent seems to exclude the idea of pernicious anæmia. The extirpated spleen was found to weigh 500 grammes. There was no perisplenetic capsular thickening, and no marked increase of connective tissue was shown on histological examination. The most striking feature of the organ was the extreme hyperæmia. The lymph follicles were normal: myeloid cell elements abounded in the pulp, of which a very large number were eosinophile. The abundance of pigment is also specially notable, in form of coarse granules and rods, which are found almost exclusively within the cells, and bears full testimony to the previous intensity of the blood destruction. Satisfactory proof of the iron reaction has not hitherto proved demonstrable as regards those cells. Whether the case is to be regarded as one of actual cure, or an instance of remission of symptoms due to splenectomy, is a question which can be decided by the sequel only.

The same physician also showed a patient, æt. 18, who was affected with

SPLENOMEGALY AND ICTERUS.

His father had died of progressive paralysis; there was a brother who was healthy; there was no family record of icterus. Ever since he was two years old this youth had had enlargement of the spleen; there had been recurring attacks of icterus, of which the first was in his twelfth year, and lasted two months. There had been no marked general disturbance of the system with it, excepting pronounced cutaneous irritation. About a year later there was another attack, which lasted three months. Some years later again there was some slight jaundice, which had but a brief duration. The present attack had lasted five months. Of subjective symptoms, there were but a slight cutaneous irritation and hemeralopia. Independently of the attacks of jaundice, the patient had for the past six years suffered from, approximately, annual attacks of acute pain in the neighbourhood of the right kidney, which did not radiate from its focus; it lasted for about eight days, and ended with alvine evacuations of fæces and gas. The urine was unaffected. In his ninth year he had two attacks of hæmatemesis, without any pronounced symptoms. A year ago he had passed blood-stained urine after severe walking exercise. There had been no fever with any of these attacks. At present the patient, who displays indications of a hypoplastic constitution, is deeply affected. The lungs and heart are unaffected. The spleen is greatly enlarged (18 by 14 c.m.), easily movable, and the liver reaches two fingers' breadth below the right costal margin. There is no ascites and no alimentary galactosuria. The urine is very dark in colour and contains a great deal of biliary pigment, in addition to urobilin and bilinogen; no hæmoglobin. The alvine evacuations are normal in colour and rich in bilinogen. Optic disc is normal. Röntgen-ray examination gave no evidence of nephrolithiasis. Wassermann negative. Examination of the blood showed: Erythrocytes, 3,800,000; hæmoglobin, 80 per cent.; colour index, 1; leucocytes, 2,300. Many granulo-filamentous erythrocytes, which showed sub-vital coloration. The disc resisted normal salt solution. Donath-Landsteiner test gave negative result. Neither autolysin nor isolysin was found in the serum. The sera of six different patients were tried, but only two produced marked solution of his erythrocytes. The case probably should be described as one of splenomegaly with hæmolytic anæmia—but not referable to any of the typical categories (morbus Banti, icterus hæmolyticus congenitus oder acquisitus, hæmolysinicterus, splenomegalia hæmolytica Banti, anæmia perniciosa, etc.) in all its features.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

EDINBURGH CORPORATION TUBERCULOSIS SCHEME.

THE scheme of the Public Health and Local Insurance Committee, outlined in this column last week, was considered at a special meeting of the Town Council on June 24th. In moving its adoption, Mr. Macpherson alluded to the arrangement which it was proposed to make with the directors of the Royal Victoria Dispensary, and stated that the Corporation could not consent to the whole care of insured and uninsured persons being taken from the Tuberculosis Officer and handed over to the Dispensary. If the negotiations fell through it might become the duty of the Corporation to create a dispensary of its own. In the discussion which followed a number of the Councillors criticised the scheme, indicating that the Medical Officer of Health ought to be the chief tuberculosis officer, and that the Victoria Dispensary should be taken over by the town. Eventually, however, the report, except that part dealing with the appointment of a consultant, was carried by 37 votes to 3. On the question of appointing Sir Robert Philip as consultant at £500 a year further discussion ensued. The Public Health Committee held that Sir Robert Philip's appointment was essential to the smooth working of the scheme, but the minority argued that, seeing that the Victoria Dispensary authorities had not so far agreed to fall in with the Council's plan, it was a mistake to appoint Sir Robert Philip, the medical chief of the Victoria Dispensary. Eventually, however, the report was adopted by 35 votes to 5 for recommittal. At present, therefore, the position of matters in relation to the treatment of tuberculosis is rather confused. On the one hand there is the fact that in Edinburgh there already exists as a voluntary agency an unrivalled institution and apparatus for the treatment of tuberculosis, which has served as the type of what such should be in all civilised countries. The position of the managers of the Victoria Institution, if we understand it aright, and also the position of the medical men who petitioned a week ago against the appointment of an assistant to the Medical Officer of Health, is that the whole clinical part of the tuberculosis scheme should remain in the hands of the Victoria Hospital authorities, with the exception, possibly, of the segregation of advanced cases at Colinton, and that the duties of the public health authorities should be limited to the sanitary aspects of the question—housing and the like. On the other hand, there is the minority in the Council, who wish to place the whole administration, clinical as well as sanitary, under the Medical Officer of Health. The report of the Public Health Committee is an attempt at a *via media*. The underlying principle is to place the general administration under the Medical Officer of Health, through the new Tuberculosis Officer, who presumably will be a clinician, and to arrange that he shall be allowed to utilise the services of the Victoria Dispensary. To facilitate co-operation, Sir Robert Philip is made consultant, so that, we presume, the new Tuberculosis Officer will have the benefit of his advice. From a letter in *The Scotsman* of June 26th, from Sir Robert Christison, Chairman of the Victoria Hospital, it would appear that the main grounds of difference between the authorities and the Corporation concern the scope of the work allotted to the Victoria Dispensary. The Council proposal is that the Directors undertake to give dispensary treatment to all sent by the Insurance Committee and the public health authorities. The Directors apparently object to such limitations as this proposal would imply, and offer to place their whole machinery at the disposal of the town, and indicate that, in view of this the appointment of a special tuberculosis officer is superfluous. The Directors also regret that the Town Council propose to discontinue utilising the Victoria Hospital as in previous years. It is hardly conceivable, we think, but that some workable arrangement will be arrived at. The Council apparently, at last thoroughly awake to the magnitude of the undertaking, wish to erect machinery of their own, and to utilise such parts of the existing machinery as may be convenient, and they wish to have everything under their own control. The Victoria Hospital authorities, however, say in effect: "We have all this worked out from the clinical side. In following the recommendations of the Astor Report, you are merely adopting a plan modelled on the scheme which already exists in the city, and which has been evolved in Edinburgh. We do not see why you should pick and choose what we are to do, taking some parts of our machinery and superseding others by your own institutions. Let us go on doing the clinical work, you looking after the administrative and sanitary parts of the problem. On these terms we shall be pleased to co-operate."

Complimentary Dinner to Dr. Alice Hutchison.

On the occasion of her return from serving with the Bulgarian Army in the recent war, Dr. Alice Hutchison was entertained to dinner by a number of her friends, including many of the medical women practising in Edinburgh and the neighbourhood. Dr. Hutchison, who has been in practice in Edinburgh for several years, and is attached to the staffs of several medical institutions, left this country in November last as one of three medical women serving with the Women's Sick and Wounded Convoy Corps. From Sofia the corps proceeded in bullock carts to Kirk Kilisse, where their headquarters was established, Dr. Hutchison acting as Principal Medical Officer. When the convoy corps returned to London in January, the three medical women remained in the service of the Bulgarian Red Cross, and had charge of half of the 4th Base Hospital. There the English women were visited by H.M. the Empress of Bulgaria. In April Dr. Hutchison and colleagues were transferred to the field hospital at Ouzoun Keupren, whence they returned to this country. This is the first occasion on which a medical woman has had full charge of a hospital in time of war. Dr. Elsie Inglis occupied the chair at the dinner.

Suffragist Outrage at St. Andrews University.

The east wing of St. Andrews University Marine Laboratory was burned by Suffragists on Saturday, June 21st, and damage to the extent of about £500 was done. As is usual in this variety of arson, the results were less effectual than might have been expected had the fire-raisers gone about their work more skilfully, and a number of valuable original drawings, representing the work of a lifetime, escaped injury. A good deal of apparatus was damaged, some original painting were burned, while the preparations actually being worked out were, of course, ruined. The usual paraphernalia of the militants was found—soft soap on windows, tins of combustible materials, and placards bearing legends. One of the latter was rather cryptic: "We need to be goaded, like oxen as we are, into a trot." Dear, muddle-headed agitators, is it you that wish the vote, or we that deny it you, who, ox-like, require the goad?

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

MR. McKENNA, SIR VICTOR HORSLEY, AND THE R.S.C.Eng.

To the Editor of The Medical Press and Circular.

Sir,—I am obliged by your accurate statements in your "Notes and Comments" respecting Mr. McKenna's untrue and secret accusations against Mr. Mansell Moullin and myself made to the College of Surgeons seven weeks ago, and the facts of which I have only just succeeded in dragging into the light.

We made no complaints against any medical practitioner, as the Home Secretary informed the House of Commons, and we demand that he shall publicly state to whom we made such complaints, and when.

As regards the College and its disciplinary functions, it must not be forgotten that these archaic corporations rest their claim for continued existence and authority on these functions, and that they alleged to the Privy Council that the petition of the British Medical Association for a Charter would annul their powers if granted. Yet the answer of the College to Mr. McKenna surrenders the whole position.

It is quite clear that our medical corporations can, by the connivance of their officials, be made the vehicle of secret attacks on members of our profession, and it is for the Fellows and Members of the College of Surgeons to put this matter in such shape as to render such injustice impossible in the future.

I am, Sir yours, truly,
Victor Horsley.

June 24th, 1913.

THE ABUSE OF MERCURY.

To the Editor of The Medical Press and Circular.

Sir,—As an illustration of the extraordinary popularity of treatment by mercury in the early part of the last century referred to in Prof. Sandwith's lecture (Medical Press and Circular, June 25th, 1913). I remember that Sir Robert Christison used to say that somewhere about 1820, when he was a young man visiting St. Bartholomew's Hospital in London with a view to enlarging his professional knowledge, he and some other young men were in the House Surgeons' room discussing this very point, and he offered to bet that four out of five of the patients in the hospital were taking mercury in some shape or form, but his bet was not taken!

I am, Sir, yours truly,
ROBERT SAUNDBY.

140b Great Charles Street,
Birmingham.
June 25th, 1913.

INFANTILE MORTALITY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—As there were several comments in your paper regarding my letter on this matter, I wish to say that I thank your correspondents for expressing their views. I still hold to my opinion that the principal cause of the high death-rate is maladministration of food. To feed a child requires a good deal of judgment (and this requires a very long experience), as nearly every child's digestive power has a law of its own, whether in a healthy state or suffering from some disease.

I am, Sir, yours truly,
THOMAS P. CODD.

78 Lr. Drumcondra Road, Dublin.
June 22nd, 1913.

A GOOD HOLIDAY FIELD.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—The problem of the best place to go for a holiday visit has often to be settled almost at the last moment by the medical man. In casting about for a desirable spot my attention has been drawn to an extremely cheap excursion organised by the Paris, Lyon and Mediterranean Railway from London to Savoy, Dauphiny and Auvergne. Tickets are issued for July 12th, August 2nd and 30th at reduced fares, which work out roughly at £4 first class and £2 10s. to £3 second for 25 days. The headquarters are: To the Savoy, Chamonix; to the Dauphiny, Grenoble; and to the Auvergne, Clermont-Ferrand. There are several routes, and the journey can be broken at the Channel ports and at Paris, at Amiens on the S.E. and C. Railway route, and at Rouen on the L.B. and S.C. route. The return journey can be made any day. Full details can be obtained from the P.L.M. Office, 170 Piccadilly, London, W.

In my own case, the chance of a visit to either one of these delightful centres, situated as they all are in the centre of most beautiful scenery and of historic associations, has helped me to solve the holiday problem out of hand. The fares are moderate, and living is inexpensive to those who know how to choose the right hotels. Enthusiasm at the prospect thus opened up is my only excuse for asking you to insert this letter.

I am, Sir, yours truly,
AN OVERWORKED PRACTITIONER.

London, N.W.
June 28th, 1913.

OBITUARY.

SIR JONATHAN HUTCHINSON.

WE deeply regret to record the death, briefly announced in our last issue, of Sir Jonathan Hutchinson, F.R.S., LL.D., F.R.C.S., which took place at his residence, The Library, Inval, Haslemere, on June 23rd, in his 85th year. The deceased, who was well termed the "grand old man of surgery," was born at Selby, Yorkshire, on July 23, 1828, the second son in the large family of Jonathan and Elizabeth Hutchinson (*neé* Massey), both originally from Lincolnshire, and members of the Society of Friends. Jonathan was educated at home, or at a day school in his native town, and was conspicuous from childhood for his studious habits; light literature of every kind was withheld from him by the wishes of his father. At 16 he left school to be apprenticed, as the custom then was, to Mr. Caleb Williams, a leading surgeon in the city of York, under whose direction he attended lectures and hospital practice at the medical school there, which was then a very small one and has long ceased to exist. In 1850, at the close of his apprenticeship, he came to London and entered as a student at St. Bartholomew's Hospital, whence he qualified as M.R.C.S. and L.S.A. in 1850. Six years later he married Miss Jane Pynsent West, a daughter of William West, F.R.S., of Leeds, after he commenced surgical practice in London, being first appointed to the Metropolitan Free Hospital. A few years later he was elected upon the staffs of the London Hospital, the Royal London Ophthalmic Hospital, and the Hospital for Diseases of the Skin, Blackfriars. Early in his professional life he took an interest in leprosy, and in 1869 he visited Norway in order to observe and study the disease in one of the places of its chief prevalence, and, having early arrived at the conviction that it was associated with the use of badly cured fish, he spared neither trouble nor expense in the endeavour to obtain conclusive evidence upon the question. His conviction on the matter was very generally received with incredulity, and, although as years went on this incredulity underwent marked diminution, Hutchinson never ceased to regret the opposition which his views had encountered, with the consequence, as he believed, that an easily attained reduction in the prevalence of the malady was delayed, and that what he regarded as the gross cruelty and injustice of the compulsory segregation of lepers was still, although only in a few places, continued. During 1899 and 1900 he visited South Africa on leprosy work, and in the following year made a tour for the same purpose in Ceylon and India, and lectured upon the subject in several medical schools. In 1906 he visited Switzerland to inquire into an outbreak of leprosy in the Rhone Valley, and in August, 1909, when already in his 82nd year, he paid a second visit to Norway in order to attend a conference upon leprosy at Bergen. In 1865 Hutchinson obtained the Astley-Cooper triennial prize of 300 guineas for his essay on "Injuries to the Head," and some years later he was elected a Fellow of the Royal Society, although he seldom took part in its proceedings. At various times he was president of nearly every medical society in London, and he presided over the third International Triennial Congress of Dermatology. At the age of 80 he was the recipient of a special vote of congratulation from the Royal College of Surgeons of England, of which he was a former President. His untiring zeal and devotion in the cause of science was preserved until a comparatively short time ago. Those who were fortunate enough to hear him deliver a discourse at the Dermatological Section at the annual meeting of the British Medical Association, held in London in 1910, will remember the zest and energy which he threw into his highly original remarks upon "Paleogenesis as illustrated in certain affections of the skin," though he was obviously far from well at the time. Perhaps the greatest monument to Sir Jonathan consists in the Polyclinic, or Medical Graduates' College, to which he gave its name and support. He was always a strong advocate of pictorial illustration as an aid to teaching, and at the Polyclinic there is a collection of pathological drawings, made and collected entirely at his own expense, which has no rival in any medical centre of the world. He has founded at Selby, in Yorkshire, where he was born, and at Haslemere, in Surrey, two museums, chiefly, but not entirely, devoted to natural history. These museums are well known and have proved most valuable. The Haslemere Museum was built, stocked, and is maintained at his sole expense, and contains some novel features. In it are stored specimens of natural history, maps, charts and historical portraits, which are so remarkable that it is felt that such an institution is worthy of a wider field.

In his published writings Sir Jonathan showed the same acumen that characterised his clinical teaching, and his "Archives of Surgery," "Illustrations of Clinical Surgery," "Clinical Lectures on Rare Diseases of the Skin," are standing monuments to his skilful insight and investigation into disease. He received the honour of knighthood in 1908, but his door-plate was never altered from "Mr. Hutchinson." So has passed a great and noble man, famous alike as surgeon, syphilologist, neurologist, dermatologist, and ophthalmalogist, and the whole medical profession will indeed mourn his loss.

MEDICAL NEWS IN BRIEF.

West London Medico-Chirurgical Society

The annual general meeting of this Society will be held on Friday, July 11th, in the College Class-room, under Devonshire Ward, West London Hospital. The chair will be taken by the President, Mr. G. P. Shuter, at 5 p.m. The general meeting will be preceded at 4.55 p.m. by a special meeting for the election of new members. After the presentation of the annual report, the financial statement, etc., the ballot for officers for next session will take place, Dr. F. S. Palmer, Physician to the West End Hospital for Diseases of the Nervous System, being nominated as President.

Medical Sickness and Accident Society.

At the usual monthly meeting of the Executive Committee of this Society, held a few days since, Dr. J. F. Allan in the chair, the accounts presented showed that the sickness claims were decreasing with the advent of the warmer weather. The number of claims through motor cycle and car accidents is increasing, and the severity of some of these is shown by the fact that one member at least has been on for two years, and many others of varying durations from two months downwards. Fractured arms from back fires when starting are the most frequent cause of accident.

The new business has been well up to the average, and there is a growing desire among the profession to get covered against sickness and accidents, and, as is so often the case, many members come to the Society from other companies when they find out that the Society's rates are so much lower than the others.

Taking at random three examples of claims by members it was found that although they had only paid £521 in premiums they had received over £4,790 in sickness pay during their membership.

Epsom College.

The annual general meeting of the Governors of Epsom College was held the other day at the office in Soho Square, the Treasurer, Sir Henry Morris, presiding. He was supported by Sir Francis H. Champneys, Sir William S. Church, Sir James Reid, Surg.-General Sir Lionel D. Spencer, and other Governors. The annual report stated that since the last annual general meeting H. W. Hodges had gained a classical exhibition at Hertford College, Oxford, and A. J. M. Lander had taken a similar exhibition at Sidney Sussex College, Cambridge. Last year there were over 150 members in the Officers Training Corps, of whom five passed the examination for certificate "A." At the conclusion of the meeting a vote of thanks to Sir Henry Morris for the great services which he renders to the College as Treasurer, was moved by Sir William Church, seconded by Sir James Reid, and carried.

Proposed Memorial to the late Sir Henry R. Swanzy.

A meeting will be held in the Royal College of Surgeons, Dublin, on Thursday, July 3rd, at 4 p.m., to consider what would be the most appropriate form of a memorial to the above-named eminent ophthalmic surgeon, to whose unfailing energy and public spirit Ireland mainly owes the magnificent Royal Victoria Eye and Ear Hospital which is now established in Dublin. The meeting is summoned by the Right Honourable Lorcan G. Sherlock (Lord Mayor of Dublin), the Lord Chancellor of Ireland, the Earl of Pembroke, the Earl of Meath, Lord Monck (President Royal Victoria Eye and Ear Hospital), Lord Ardilaun, Mr. W. D. Andrews, Mr. W. M. Murphy (President Chamber of Commerce), Mr. James Henry (President Incorporated Law Society), the President Royal College of Physicians, and the President Royal College of Surgeons.

Honorary degree for Sir Robert Woods.

The following is a translation of the Latin oration made by the Public Orator of Dublin University (Dr. A. C. Purser), in presenting Sir Robert Woods for the honorary degree of M.Ch. last Thursday:—

Our list closes with the name of a man known to all, admired by all, loved by us all, Sir Robert Henry Woods, who a year ago held with eminent distinction the Presidency of the Royal College of Surgeons in Ireland, and has lately received from the King the well-deserved honour of knighthood. Educated in our halls, where he graduated with first-class honours in Physics and Chemistry, he is able to use these sciences very often in the practice of his profession, and, always thinking from what I may call a physical basis, he often disdains to adopt a treatment "of common mintage, hackneyed, worn and bad," but applies new and original and most effectual methods of cure, whereby in perfectly marvellous wise are the patients made whole. Your nose is deformed, either by Nature or disease: Woods will make it quite shapely. You are deaf: Woods will restore your hearing. It may be that you are not averse from hearing your own voice, and yet your throat suffers from some malignant affection so that, poor soul, you cannot utter even a word: Woods better than anyone else will cure that tragic condition. As lately into the throat of a patient whose vocal cords had been cut out he inserted new cords—cords of brass—made by himself—you must admire his mechanical ingenuity and skill—with the result that the dumb man as by miracle spoke clearly and distinctly. Virgil alludes to such a voice as absolutely impossible when he says—

> "Nor could I, though I had a hundred tongues,
> Utterance a hundred-fold and iron voice";

but that was before Woods lived. Nowadays he might have got such a voice (which Lucretius, too, desired might have been granted him), and have

> "The types of guilt in their full number traced,
> And run through all the forms of penal woe";

and so the sixth book of the Æneid would have (good gracious!) increased a hundredfold, which consummation, however, the Fates have properly denied.

In Great Britain Woods is highly esteemed: he has been President of the Laryngological Society and Vice-President of the Laryngological Section of the British Medical Association.

> "So thus from fame to fame his glory grows."

But we here owe him a special debt of gratitude, as he has not forgotten his University, but in lectures to our medical post-graduate classes pours out to them the wealth of his learning, and inspires them with his own enthusiasm. To a man, then, of such high character, eminent distinction, ingenious originality, and gracious kindliness, our attached friend, now give your applause, and again I say give your most resounding applause.

Dublin University.

The following medical degrees were conferred by Dublin University last Thursday:—

Baccalaurei in Medicina, in Chirurgia, et in Arte Obstetricia.—Edgar Noel Bateman (antea Lic.), Hedley Boyers, Henricus Bryan Frost Dixon, Mabel Alice Dobbin, Henricus Launcelottus D'Olier Duckworth, Robertus Andreas Georgius Elliott, Guilelmus Franciscus Evans, Carolus Douglas Goodenough, David Hamilton Hadden, Ricardus Stopford, Gilbertus Halpin, Benjamin Johnson (antea Lic.), Thomas Jacobus Kelly, Radulphus Johannes Ricardus Mecredy, Guilelmus Jeremias Merrick (B.Ch. stip. cond.), Carolus Joseph O'Reilly, Johannes Thomas Simpson, Jacobus Alexander Small.

Magister in Arte Obstetricia.—Samuel Georgius Steele Haughton.

Doctores in Medicina.—Gualterus Eustace Adam, Ricardus Johannes Attridge, Eduardus Jacobus Hamilton Garstin, Johannes Franciscus Nicholson, Jacobus Noel Greene Nolan, Johannes Alfredus Guilelmus Ponton, Jacobus Harloe Christophorus Thompson, Reginaldus Tate Vaughan.

In Absentia.

Licentiatus in Medicina, in Chirurgia et in Arte Obstetricia.—David Ludovicus M'Cullough.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Contributors are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

Reprints.—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Dr. A. S. G. (Aix-les-Bains).—MS. duly to hand.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

The annual meeting of the above Association will take place on July 16th and 17th at the rooms of the Medical Society of London, when a presentation will be made to Dr. H. Hayes Newington, a member for forty years, President in 1889, and Treasurer since 1894. The Presidential Address will be delivered by Dr. James Chambers. Several interesting and important papers are to be read and the report of a special committee on the status of assistant medical officers and the position of psychiatry will be discussed. The proceedings will terminate with a garden party, given by the President and Mrs. Chambers, at the Priory, Roehampton.

Mr. D. Spores (Worthing).—We can hardly credit the legend that chronic bronchitis may be "completely cured by the eating of pineapple." The fruit is of considerable value as a food, and it is said to contain a digestive ferment.

THE CURABILITY OF DIABETES.

In reference to the Clinical Lecture by Prof. Robt. Saundby, published in our last week's issue, we are asked to state that the Brusson Jeune Bread, recommended by the author, is obtainable of the Therapeutic Foods Co., Bedford Chambers, Covent Garden, London.

"Hopeful" (London, E.).—The researches of Dr. W. Gordon, of Exeter, have shown abundantly the influence of rain-bearing winds upon the incidence of phthisis. We should prefer a place of a higher latitude for permanent residence than the one you mention, though with suitable drainage of the subsoil it might be tenanted for a while with safety.

AS OTHERS SEE US.

The Refereé the other day published the following:—"Panel doctoring is not all rose-leaves, neither is being panel doctored. The other day in a country district a gardener employed by a friend of mine was taken ill and could not come to work. In the afternoon my friend went to the cottage to see how the man was. He arrived just as the panel doctor was laying down the law to the sick man's mother. 'Look here,' said the doctor, 'your son's got pneumonia. He's strong and healthy, and if you feed him properly and as I say, he'll get all right. But remember another time if you want me you must send word the night before I've done this district once to-day.'

"One can quite understand the doctor's view, but's it's a little rough on the invalid. It is not everybody who can send word to the panel doctor on Thursday evening that he is going to be taken seriously ill on Friday afternoon."

Dr. S. R. (Yorks).—One of the greatest objections to the diagnosis of lymphatism or status lymphaticus is that it may become a diagnostic refuge for the destitute. Dyspnœa, stridor, inspiratory retraction of the chest, and increased dulness on percussion over the thymic region suggest the presence of the disease. In the majority of cases the thymus will be found at the autopsy regardless of the age of the subject.

Mr. H. Redding (London, E.C.).—According to the *Financial News*, a further substantial advance was made last year in the business of Virol, Limited The establishment of research laboratories and their extension to the service of the medical profession for the investigation of clinical material has met with widespread approval, and both medical men and public bodies all over the country are even now availing themselves of the service of these laboratories.

Meetings of the Societies Lectures, &c.

Thursday, July 3rd

Royal Society of Medicine (Section of Obstetrics and Gynæcology) (1 Wimpole Street, W.).—8 p.m.: Dr. H. S. Souttar: Calcified Fibroma of Ovary Obstructing Labour. Paper: Mr. Charles P. Childe: Suggestions for the Technique and Performance of Wertheim's Abdominal Panhysterectomy. 9 p.m.: Presidential Address: Dr. Amand Routh: Observations on the Toxæmias of Pregnancy and on Eugenics from the Obstetrical Standpoint.

Appointments.

Barlet, Jehan M., M.D.Brux., L.R.C.P.Lond., M.R.C.S., Anæsthetist to the French Hospital, London.

Biddle, H. G., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Acts for the Hoxne District of the county of Suffolk.

Craig, J. A., F.R.C.S.Eng., Lecturer on Ophthalmology in the Queen's University of Belfast.

Dearnley, Gertrude, M.B., B.S.Lond., Clinical Assistant at the Royal Free Hospital.

Gazdar, Gertrude, M.B., B.S.Lond., Curator of the Museum at the Royal Free Hospital.

Hattersley, S. M., M.R.C.S., L.R.C.P.Lond., House Physician at the Manchester Royal Infirmary.

Magill, R., jun., M.B., B.S.Dub., Certifying Surgeon under the Factory and Workshop Acts for the Newcastle District of the county of Down.

McCartan, P., L.R.C.P. and S.Irel., Certifying Surgeon under the Factory and Workshop Acts for the Gortin District of the county of Tyrone.

Messenger-Pearson, Mrs., M.D., C.M.Canada, Clinical Assistant at the Royal Free Hospital.

Raper, H. S., M.B., Ch.B.Leeds, Lecturer in Chemical Physiology at the University of Leeds.

Seligmann, C. C., M.D.Lond., F.R.C.P.Lond., to the part-time Chair of Ethnology at the London School of Economics.

Stewart, A. G., M.D.Aberd., Medical Superintendent of the Paddington Infirmary, W.

Vacancies.

Free Eye Hospital, Southampton.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry. Applications to E. Burton, Hon. Secretary.

Three Counties Asylum, near Hitchin.—Junior Assistant Medical Officer. Salary £200 per annum, with board, furnished apartments, washing, and attendance. Applications to the Medical Superintendent.

The University of Liverpool.—Faculty of Medicine.—Walter Myers Chair of Parasitology. Salary £600 per annum. Applications to P. Hebblethwaite, M.A., Registrar.

Durham County Asylum.—Third Assistant Medical Officer. Salary £180 per annum, with board, lodging, and washing. Applications to the Medical Superintendent, Winterton, Ferryhill.

Durham County Asylum.—Fourth Assistant Medical Officer. Salary £180 per annum, with board, lodging, and washing. Applications to the Medical Superintendent, Winterton, Ferryhill.

Kent County Asylum, Chartham, near Canterbury.—Junior Assistant Medical Officer. Salary £220 per annum, with furnished apartments, lighting, heating, attendance, laundry, milk, and garden produce. Applications to Medical Superintendent.

Hampstead General and North-West London Hospital.—Resident Casualty Officer. Salary £140 per annum, with board, residence, and laundry. Applications to A. E. Thomas, Secretary, Haverstock Hill, N.W.

Horton Infirmary, Banbury.—House Surgeon. Salary £100 per annum, with board, and residence in the Infirmary. Applications to E. Lamley Fisher, Hon. Secretary, Horton Infirmary, Banbury.

Births.

Butler.—On June 24th, at 269 Goldhawk Road, London, W., the wife of J. A. Butler, M.D., of a daughter.

Derham-Reid.—On June 29th, at Auchinellan, St. Helen's Road, Bolton-le-Moors, the wife of James Derham-Reid, M.R.C.S.Eng., L.R.C.P.Lond., of a son.

Grisewood.—On June 24th, at Egremont, Cheshire, to Captain and Mrs. A. E. Grisewood, I.M.S., a son.

Verdon.—On June 24th, at Shamrock, St. Michael's Road, Dovercourt, Essex, the wife of Staff Surgeon J. Verdon, Royal Navy, of a daughter.

Marriages.

Linton—Asquith.—On June 24th, at St. James's, Piccadilly, Stanley Fox Linton, M.B., B.Sc., of Scarborough, to Mary Pemberton Asquith, younger daughter of the late T. W. Asquith, of Harperley Hall, County Durham.

Deaths.

Booth.—On June 23rd, at 30 Swan Street, Manchester, William Grounds Booth, L.R.C.P.I. and L.M.

Willett.—On June 30th, at Wyndham Croft, Turners Hill, Sussex, Alfred Willett, F.R.C.S., Consulting Surgeon to St. Bartholomew's Hospital, aged 76.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, JULY 9, 1913. No. 2.

NOTES AND COMMENTS.

Measurement in Medical Science.

AMONG the statesmen of the present generation, Mr. Arthur Balfour stands in the front rank as a philosophic thinker. At the recent opening of the new buildings of the National Physical Laboratory at Bushey, he urged that an enterprise of that kind should not be left to private benefaction. Measurement he held to be the very life-blood of all the physical sciences, in spite of the large number of things that could not be measured. Life cannot be measured, beauty cannot be measured. happiness cannot be measured. The air-waves of a great symphony can be gauged, even their energy can be estimated to the highest overtone, but we cannot measure the symphony itself. If we had a standard of happiness, politics would become a more exact science than it is at present, or than it is ever likely to become. So far as medical science is concerned the application of Mr. Balfour's views is of interest. Progress has travelled hand-in-hand with accuracy of measurement. Take the case of the microscope which has contributed so greatly to medical discovery. From the simple magnifying lens it has developed into the modern instrument which brings well-nigh inconceivably minute micro-organisms within the range of human vision. The best modern microtome, moreover, is capable of cutting with undeviating accuracy sections of tissue down to 1 μ in thickness. Instances of a similar nature abound in medicine and its cognate sciences. It may be said broadly, indeed, that ignorance of a given medical subject depends on the absence or defectiveness of methods of measurement with regard to it.

Of National Importance.

THE tissues of the human body have been investigated with ever increasing accuracy of measurement by the anatomist, the physiologist and the pathologist. An enormous mass of knowledge has accumulated regarding the physical basis of life, but for all that life itself remains elusive from our grasp. As in the case of a symphony, while it is possible to analyse and measure the forces and agencies whereby it is created, yet the abstract product we call the symphony lies beyond the compass of our human standards. Nor does it seem likely that the ultimate mystery of life will ever be within the grasp of science. On the other hand, it is unsafe to assume that anything will remain permanently outside the range of that science which has already established so vast a command over the material facts of existence. A great impulse has been given to the study of the problem of life by the fact that tissues can be grown in the laboratory apart from the living body. It is obvious that progress of this kind may have an important economic value to the community, to say nothing of their direct and indirect bearing upon the happiness of mankind. From that point of view every argument advanced by Mr. Balfour as to the desirability of national endowment applies a hundredfold to the wisdom of State aid for medical research. Much of the work now achieved by private enterprise is crippled and hampered by the need of costly apparatus and of costly upkeep and administration.

The Cure of Whooping Cough.

WHOOPING cough, in spite of the terrible havoc it plays with our juvenile population, is not—so to speak—one of the romantic diseases. The popular imagination is not readily stirred up against this prosaic malady as it is, say, against cancer, tuberculosis, small-pox, or spotted fever. For all that, whooping cough probably destroys more lives than the four diseases in question taken together. Why should not Government endow a research committee to investigate whooping cough? £57,000 has been found for a similar purpose as regards tuberculosis. To put the matter bluntly, lives saved to the State represent much the same value whether they are rescued from death by tuberculosis or any other preventable malady. There can be little reasonable doubt that some specific pathogenic organism constitutes the *fons et origo* of whooping cough, although its identity has not been so far established. News has recently come from Paris to the effect that Dr. Nicolle, one of Metchnikoff's principal collaborateurs at the Pasteur Institute, has succeeded in obtaining a curative vaccine for whooping cough. For a long time past he has been engaged in a laborious investigation on the virus of that disease. It is said that his vaccine when administered to children suffering from whooping cough leads in some cases to speedy cure, and in others to a marked mitigation of symptoms. If this be the case his discovery will be hailed with acclamation by the medical profession throughout the world. Whether this be the much wished for remedy or not it seems a simple truism to say that we in the United Kingdom should possess an official laboratory and skilled staff ready instantly to investigate a remedy which if effectual would save a vast number of lives and prove of incalculable economic value to the community.

Seaside Medical Benefit.

THE question of medical benefit of insured persons at the seaside does not seem to be advancing much nearer towards a satisfactory arrangement. It seems fairly obvious that the per caput payment is so small that it would be unfair to deprive the regular panel attendant of any portion of the amount, while it would, on the other hand, be impossible to provide the temporary seaside attendant with any adequate fee from the same source. The problem bears heavily on Southport in view of the large summer population of immigrant visitors. The medical men of that town have taken a firm stand in the matter and the Medical Committee has sent a communication to the local Insurance Committee saying that they cannot consent to the method proposed by the Commissioners for the payment of medical attendance on temporary residents out of a central pooled fund formed by deductions from the amount due to the medical practitioners on whose lists the names of these temporary residents normally appeared. The Medical Committee urge that the only fair method of dealing with this problem was by the provision of a central fund financed entirely apart from the sum now set apart for medical benefit. There the matter stands for the present.

A Princely Gift. The exact site of the London University has not yet been determined. The London County Council is anxious to have it pitched on the south side of the Thames next to the palatial building now being erected for its own municipal home. The suggested location near the British Museum was negatived because it was not large enough for the purpose. There is a fine central position available on the large plot of ground owned by the Foundling Hospital, which is to be removed into the country, but the cost of the property would probably be about half a million, and it is doubtful whether the University could pay so large a sum. The necessary funds may, of course, be forthcoming, for the springs of benevolence seem inexhaustible among wealthy philanthropists of the United Kingdom. Some six years ago some of our readers will remember an anonymous donation of £50,000 was presented to the Royal College of Surgeons of England to enable it to be incorporated with the University of London. A few days since Professor P. G. D. Thane, Dean of the Faculty of Medical Science, announced the name of their benefactor—Sir W. Gwynne Evans, who has recently had a baronetcy conferred upon him. Prince Arthur of Connaught has become President of the Fund. Professor Thane also announced that the whole of the money required for the purchase of the Flinders Petrie Egyptian collection had been raised.

LEADING ARTICLES.

THE FUTURE OF THE VOLUNTARY HOSPITAL SYSTEM.

Everyone recognises the vast importance of the part played by the voluntary hospital system in the complex social life of the United Kingdom. It is the outcome of philanthropy aided by accumulated and increasing prosperity, and from one point of view it may be regarded as a sort of acknowledgment that the division of wealth is not irreproachably just among the various classes of society. In its economic and socio-political aspects, indeed, the underlying principles of our voluntary system may be regarded from widely differing standpoints. Some advanced thinkers, for instance, do not hesitate to assert that what the philanthropic do in this way from their private benevolence should be provided by the State at the cost of the community. That contention, crude as it may seen at the first glance, has in reality been long accepted as a guiding factor in British legislation. The Poor Law of Queen Elizabeth formally acknowledged the responsibility of the State for the bodily welfare of the poorer citizens. Later developments have ended in the formation of an elaborate system of medical relief, both institutional and outdoor, with an elaborate classification and with the nucleus and, in some instances, the full fruition of applied modern medical science. Last of all has come the National Insurance Act, which has taken over the medical care of the working classes with a comprehensive thoroughness never previously attempted by the State. Altogether, it looks as if the voluntary hospital system must sooner or later be superseded by a national organisation. Professor Sir William Osler, who is always outspoken, entertains no doubt upon the subject. As President of the British Hospitals Association, he recently suggested that the days of the voluntary system were numbered. That somewhat melancholy conclusion, however, appears to have been based not so much on the effects of the Insurance Act as on the inefficiency of the hospitals themselves. The pathological arrangements of those institutions were, he affirmed, not "out-of-date" simply because they had never been in date. Defining "pathological arrangements" widely enough to include the work of a first-rate clinical laboratory, there is much to be said in support of his contention. Without such aids to modern scientific diagnosis and treatment, a voluntary hospital would find it not altogether easy to justify its claim upon the public. On the other hand, it is to be presumed that a properly organised State system would take care to provide all necessary scientific equipment. Failing such provision a State hospital system would be a snare and a delusion, and the last state of the working-class populace would be worse than the first. It is not clear whether Sir William Osler proposes to sweep away at one stroke the whole of our magnificent voluntary system. Presumably he would make an exception in the case of some of the more ancient and more efficient hospitals, such as those attached to the great medical schools and other centres of learning. It would be interesting to have his views as to the possibility of effecting some sort of compromise whereby the State would come to the aid of the voluntary medical charities and enable them to render themselves up-to-date as regards modern science. This kind of advance is merely a question of money, and it may be taken for granted that the members of the honorary medical staffs of those institutions have in a vast number of instances been woefully handicapped by the poverty of the hospitals to which they are attached. However the voluntary problem is approached it is found to end ultimately in the dominating factor of finance. Year by year medical relief grows more costly as it grows more complex and, as we believe and hope, at the same time more efficient. It is difficult to contemplate calmly the possibility of the loss of our magnificent voluntary system. One would fain hope that British statesmanship will bring about some satisfactory compromise whereby a solid and lasting union will be effected between State and voluntary efforts for the medical guardianship of the poorer population of the United Kingdom.

THE IRISH INSURANCE COMMISSION AND THE INTERIM REPORT.

The terms of reference of the Departmental Committee on Tuberculosis were "to report at an early date upon the consideration of general policy in respect of the problem of tuberculosis in the United Kingdom, in its preventive, curative, and other aspects, which should guide the Government and local bodies in making or aiding provision for the treatment of tuberculosis in sanatoria or other institutions or otherwise." The Committee performed its duties with so much ability and comprehension of the subject that its recommendations have been accepted by the official authorities as laying down the lines along which the campaign against tuberculosis was to be conducted. The Irish Insurance Commission very properly circulated the interim report to the various insurance committees in Ireland, with the suggestion that, as far as possible, its recommendations should be followed. This advice was in many areas accepted and followed with great success during the past twelve months. Within the past few weeks, however, the Irish Commissioners have changed their minds, and have declared to the Dublin County Borough Insurance Committee that it will not be permitted to carry out the recommendations of the interim report in one particular, declared in that report to be "of primary importance." The point is that dealing with the relation of general practitioners to tuberculosis schemes. The interim report declares (par. 28) "that it is of primary importance to the lasting success of any scheme for dealing with tuberculosis that it should enlist the hearty co-operation and stimulate the interest of the general practitioners of the country. Their intimate personal relations with patients and their influence in the homes of the people are forces which should be actively enlisted in the campaign against the disease as aids to securing its early recognition and methodical treatment." Again, in the "Summary of Principal Recommendations" (par. 42), it is urged "that special regard should be given to securing the co-operation of medical practitioners in the working of the schemes, *particularly in relation to the early recognition of the disease.*" In discussing the relation of insurance committees to the scheme, the Departmental report declares that among the "duties" of insurance committees will be:—"(*a*) That of securing prompt official notice wherever suspicion arises that an insured person (or possibly a dependant) is suffering from tuberculosis; (*b*) that of obtaining proper evidence as to whether such person is in fact suffering from tuberculosis." And it is further stated that these duties "must be discharged by making suitable arrangements with medical practitioners for reporting cases to the Committee, and for making the confirmatory diagnosis when required." This duty was loyally discharged by the Dublin Insurance Committee, who, acting on the advice of the Commissioners, were in the habit of paying a fee of five shillings for a preliminary report on a case of tuberculosis from the applicant's own medical attendant. This plan has worked with great success, and the Insurance Committee has dealt with a very large number of cases of tuberculosis, probably more in proportion than any committee in the Kingdom. The Commissioners, however, in a recent letter to the Insurance Committee, have declared that after July 1st, the Committee cannot pay these fees out of its funds, but that they must be paid, if at all, by the applicants themselves. We do not wish to suggest the motives which have led the Irish Commissioners to treat with contempt the interim report which one of them had signed. We view with the deepest regret the injury to the administration of the sanatorium benefit which is bound to follow. Up to the present, the working of the benefit has had the cordial co-operation of the medical profession of Dublin, general practitioners and hospital physicians and surgeons. The seed of dissension has been deliberately and wantonly sown by the Commissioners.

CURRENT TOPICS.

The Annual Election at the Royal College of Surgeons, England.

The annual election of members of the council of the Royal College of Surgeons, England, took place on Thursday last, July 3rd. It was an eventful contest, owing to the unusual number of vacancies to be filled, namely, four. These were due to the retirement in rotation of Mr. Edmund Owen and Mr. Golding Bird, who did not seek re-election—to the resignation of Mr. Bruce Clarke, who has left London, and to the death last year of Mr. Clinton Dent. For these vacancies there were seven candidates, namely, Mr. Ernest Lane (St. Mary's), Mr. J. H. Waring (St. Bartholomew's), Mr. L. A. Dunn (Guy's), Mr. Jonathan Hutchinson (London), Mr. W. G. Spencer (Westminster), and Mr. H. B. Robinson (St. Thomas'). Save for the fact that Sir R. T. Godlee occupies the presidential chair, there would have been a fifth vacancy, inasmuch as his term of office expired in the current year. At the close of the poll the President declared the first four named above to have been duly elected members of the council, the first two for the full term of eight years, the two latter as substitute members for the vacancies created by the resignation of Mr. Bruce Clarke, and the death of Mr. Dent. The substitute member for Mr. Bruce Clarke will be required by the rules to retire in 1915.

while Mr. Dent having been re-elected in 1911, his term would not have expired until 1919. It is interesting to note the strenuous rally of the large Metropolitan medical schools in favour of their representatives. Mr. Lane takes the place of his colleague, Mr. Owen, at St. Mary's Hospital, Mr. Waring, of Mr. Bruce Clarke, at St. Bartholomew's, Mr. Dunn, of Mr. Golding Bird, at Guy's. Thus the proportional representation of these schools on the council is still maintained. Furthermore, it is noticeable that no provincial fellow competed at this election, the reason probably being that the contest did not involve a change in the provincial representation—limited enough as this is. Out of the whole number of twenty-four members, of which the council is composed, only three members represent the medical schools of the provinces.

Antidote Slips.

Some of the large drug houses put little labels on the containers of their poisonous goods which suggest a suitable antidote in cases of accidental consumption of the contents. The idea is worthy of extension, as most people's ideas of first aid in such circumstances are rather vague. Care should be taken that the antidote is easily obtainable in the average home and is called by its own familiar name. Some idea of the quantity of the antidote should be given or we shall find about a pint of lime water administered in the hope of neutralising anything up to an ounce of, say, oxalic acid, which is absurd. There are not many grounds for opposing these labels. The experimental suicide might be tempted to poison himself more readily if he thought he had an antidote at hand to recall his spirit from the vasty deep in case of an eleventh hour repentance; but that would not often happen. One of the best antidotes for carbolic acid is whiskey—although it is not given in the majority of text books—and there might be an increase in the alleged consumption of the former for the antidote's sake. It happened in a Dublin hospital that after a man had three bottles of "John Jameson" administered free gratis and for nothing, there followed an epidemic of poisoning with imaginary phenol. Apart from such trifles, the labelling of every poisonous product with some simple treatment in case of accident would be well worth the little trouble involved.

Hodie Vacandi.

The warm weather has brought out the mosquitoes—and in obedience to the inexorable laws of supply and demand there now appears in large numbers the mosquitoes' prey—the holiday-maker. Now the holiday-maker is quite different from the man who is taking a holiday. The latter is an uninteresting person who goes where he wants to and does what he likes. The former suffers on principle. He is obeying as a duty the Laws of Health, as his kind understand them. They say—"Go to a place by the silvery sea where the greatest number of human beings is compressed into the smallest area and there do all the things you never have done and leave undone all the things you usually do." It is quite true, nevertheless, that at the ordinary pleasure resort we see many happy faces exuberant with health and *joie de vivre*. Not everyone is taking his pleasures sadly; some seem even glad to be alive—and we may be led to think that the jaded city worker knows what he is doing and is really getting health and strength by the application of his own peculiar principles. But we are wrong. The glad eyes and Thornton-Pickard smiles we see are not the jetsam of the cheap excursion. The visitor indeed is sad and it is the aurivorous native who wears the smile of happy villainy. Holidays are good—for the man who snares the golden tripper.

Experiences and Views of a Panel Doctor.

A recent East London inquest on a journeyman baker, aged 38, suggests some serious reflections. The young man was insured, and the panel doctor in attendance filled in the weekly certificate, giving rheumatism as the cause of the disease. Shortly before the patient's death another medical man was called in, and he stated in evidence that he at once recognised the disease from which the deceased was suffering as acute tuberculosis of the lungs. On the other hand, the medical man in attendance stated that he had notified the Medical Officer that the disease was tubercular, but at the same time he admitted he had taken no steps to get the patient into a sanatorium. The relatives of the deceased declared that the doctor said panel patients were a great nuisance, and he got only three-halfpence a week from the Prudential. It is difficult to believe any responsible medical man would have expressed the views as to the nature of a medical certificate attributed to the doctor in question by the *Daily Express*. "When I first saw the man he spoke of chronic rheumatism. People say anything to get a certificate. The mere fact of something being on the certificate—which, I may remind you, is not a medical report—does not mean that he has got that complaint." The Coroner, himself a medical man with every sympathy for members of his profession, animadverted severely on the conduct of the medical man who after attending deceased for months certified him as suffering from rheumatism. "There can be no doubt," he said, "that if the man had been properly examined and his complaint diagnosed, it would have given him a chance to get better." The jury found a verdict of death from natural causes, and added a rider of censure upon the doctor for the language he used to the wife of deceased. The fact, elicited at the inquiry, that the medical man concerned had some 2,000 patients on his panel affords no excuse for neglect of that work which has been contracted for in precise terms with the Government. Nor is the medical certificate a document that any man can with impunity venture to deal with at random or otherwise mishandle.

International Congress for Diseases of Occupation.

The third International Congress for Diseases of Occupation will take place at Vienna in September, 1914. The first meeting took place at Milan in 1906, and the second at Brussels in 1910. There are a number of sectional subjects, such as, for instance, the physiology and pathology of fatigue; work in hot and damp air; anthrax; pneumoconioses; electrical injuries; industrial poisons; injuries of hearing, and so on. Many papers have been already promised. The member's fee is 25 crowns (25 francs), and full information can be obtained from the General Secretary, Dr. Ludwig Teleky, Vienna, IX., Türkenstrasse 23. The President of the Congress is Professor Francis Von Haberler, Councillor of the Austrian Ministry, Referee for sanitary matters to the Minister of the Interior.

Ferments and the Wash-Tub.

Scientific discoveries are of little practical use unless they can be utilised in the small affairs of everyday life. The scientist seldom shines in his domestic circle, if, indeed, he be ever found within its circumference, and he is certainly no hero to his laundrywoman. Chemical stains, dyes, and organic substances of every description have to be extracted by hook or by crook from his handkerchiefs in the weekly wash. He may think to sterilise them first before sending them to the laundry, or direct this precaution to be taken, so that the mild imprecations of our lady lavatrix mingle harmlessly with the steam and go unrecorded. Many medical textbooks give lists of the various morbid affections to which washerwomen are particularly prone, such as varicose veins, bronchitis, eczema, etc. Anything, therefore, that will lighten their labours is to be hailed with satisfaction. Those soaps which need comparatively little friction are used in preference to older varieties, while the use of diastase has resulted in the easy extraction of the old starch from soiled linen. So ecstatic lavage follows diastatic action in the wash-tub.

The Etherington Smith Memorial.

Sir Anthony A. Bowlby, on behalf of the Memorial Committee, has written to say that the subscriptions which have been received and promised for the Etherington Smith Memorial, including the sum collected by the Leander Club, amount to a little over £1,200. This sum will probably be sufficient to carry out the structural alterations required to provide the memorial, which is to take the form of special sick quarters for the medical and resident staff, but will not supply any permanent endowment. The signatories desire to thank those of our readers who have already subscribed and to make an earnest appeal to all who knew Etherington Smith, and have not yet done so, to subscribe as liberally as they can to this fund. Subscriptions may be sent to the Hon. Treasurer, Dr. T. W. Shore, Dean's Office, St. Bartholomew's Hospital, E.C.

PERSONAL.

H.M. the King has given Capt. R. G. Anderson, R.A.M.C., permission to accept and wear the decoration of the Fourth Class of the Imperial Ottoman Order of the Medjidieh, which has been conferred upon him by the Khedive of Egypt in recognition of valuable services rendered by him.

Dr. H. Leith Murray has been appointed Hon. Assistant Surgeon to the Hospital for Women, Liverpool.

Mr. Bertram A. Lloyd, M.B., B.S.Lond., F.R.C.S., has been appointed Surgeon to Out-Patients at the Queen's Hospital, Birmingham.

Dr. B. T. Edye, M.B., C.M.Sydney, has been appointed Demonstrator in Pathology in the Medical School of the University of Sydney.

Dr. John Lumb, Assistant Medical Officer and Bacteriologist at the Eastern Hospital, London, has been appointed Assistant Medical Officer of Health at Warrington.

Capt. A. J. V. Betts, I.M.S., has been appointed Resident Surgeon to St. George's Hospital, Bombay, and Professor of Materia Medica at the Grant Medical College, Bombay.

Among the recipients of the Honorary Degree of LL.D. of the University of Edinburgh, on July 4th, were Emeritus Professor Greenfield, and Dr. John Stewart, of Nova Scotia.

On Wednesday, July 23, at 12.30 p.m., Professor George R. Murray, M.D., F.R.C.P., will deliver an address on medicine at the Brighton meeting of the British Medical Association.

An oil portrait of Dr. J. Magee Finny, a past-President of the Royal College of Physicians in Ireland, has been presented to the College by his nephew, Dr. W. E. St. Lawrence Finny.

Dr. James Metcalfe, M.D.Brux., L.R.C.P., and S.Edin., has been appointed Physician in Charge of the X-Ray and Electrical Department at the Prince of Wales's General Hospital, Tottenham, N.

Mr. Alfred Lees Halkyard, of Leicester, retired physician and surgeon, who died on May 15th last, aged 57 years, left estate of the gross value of £35,190, of which the net personalty has been sworn at £31,091.

Major T. C. H. Leicester, I.M.S., has been appointed to officiate as Professor of Midwifery and Gynæcology at the Government Medical College, Calcutta, during the absence on leave of Lieut.-Col. C. R. M. Green.

On Thursday, July 24th, at Brighton, at 12.30 p.m., Ainslie Hollis, M.A., M.D., F.R.C.P., will be inducted to the presidential chair of the British Medical Association. While at 8.30 p.m. he will deliver his address in the Brighton Pavilion.

Sir Alfred Pearce Gould has sent £1,000 to the Middlesex Hospital with a request that it should be expended on the purchase of radium, which is to be used for the treatment of patients, especially those who are suffering from malignant disease.

The New Toronto General Hospital, in affiliation with the Provincial University, was officially opened on the 19th ult. by Sir John Gibson, Lieutenant-Governor, and Sir James Whitney, the Premier of Ontario.

The usual breakfast will be given by the National Temperance League at the annual meetings of the British Medical Association at Brighton, under the presidency of Dr. William Ainslie Hollis, in the Banqueting Hall of the Royal Pavilion, on Thursday, July 24th.

The Humane Society has forwarded to Dr. Bark, of Rodney-street, Liverpool, an illuminated resolution of thanks for the services he rendered to the three men asphyxiated by gas on the wrecked Ulstermore. Dr. Bark went in a small boat to the lightship and rendered aid to the three unfortunate men, two of whom recovered.

On Thursday, July 24th, at Brighton, at 12.30 p.m., the address on surgery will be delivered by Sir Berkeley Moynihan, M.S., F.R.C.S., and on Friday, July 25th, at 8 p.m., a popular lecture, entitled "Some Wonders of Animal and Plant Life in Pond and Pool," will be delivered by Edmund Johnson Spitta, L.R.C.P.Lond., and illustrated by a cinematograph.

Sir Alexander Ogston, K.C.V.O., M.D., Consulting Surgeon to the Aberdeen Royal Infirmary, has consented to accept the unanimous nomination of the Aberdeen Branch, which has been accepted by the Council of the British Medical Association, to become President-Elect of the Association for the year 1913-14. Such a choice cannot fail to give profound satisfaction, not only to members of that Branch, but also to the whole medical profession.

CLINICAL LECTURE
ON
THE SURGICAL TREATMENT OF EPILEPSY.

By Prof. Dr. O. KUKULA,

Prague.

[Specially Reported for this Journal.]

Gentlemen,—To-day I am about to call your attention to the surgical treatment of epilepsy, a subject that still retains the same practical interest which it did for us 22 years ago, when we began to approach it more nearly. This field had been backward in cultivation compared with other surgical domains—chiefly from the fact that a solid basis was not available for a surgical claim. There was, therefore, no reason for surprise that the surgeon did not promptly decide thereon, as the approach was beset with danger and the result confessedly insecure. It is only quite recently that, at least in most cases, a pathological substratum has come to be defined as the causal factor in epilepsy, and the surgical procedure could be based scientifically thereon as in other clinical conditions. For such advances we are indebted, on the one hand to the advances of neurology, and on the other to the development of surgery.

According to the explanation generally received at present, epilepsy is a chronic disease of the central nervous system; which is characterised, on one aspect, by convulsive phenomena of toxic origin; and, on the other, by nervous phenomena: prodromal, simultaneous, and subsequent. The most important modification of the nervous system is the conspicuous increase of irritability, the precise cause of which remains still unknown; and we, accordingly, refer to it here as an *epileptic* or *spasmophile* modification of the nervous system. Possibly, we have here to deal with pathological changes on a molecular scale; possibly with functional lesions which are called into existence by pathological products of metabolism (Binswanger).

With regard to the ætiology, neurologists tell us that we must distinguish between the disposition to genesis of epileptic phenomena, the development of epileptic changes, and the original causes which induced the epileptic attack.

By *predisposition* we understand an inclination to epileptic changes in the nerve-tissues. The principal factor in the origin of such predisposition is *heredity;* it produces an inclination to commencement of epileptic changes, which, according to Turner's researches, present themselves in form of various minute anomalies of the nerve-tissues; and, according to Ranke, in the case of syphilitics, manifest their presence by a peculiar flexibility of the vessels transmitted from the parents (alcoholics, luetics) to their offspring. In the case of inherited predisposition, the development of epileptic changes of tissue may be called into activity by various external causes; such as: local injury, infectious disease, psychic affections, anomalies of metabolism; auto-intoxication, &c. Among these, *trauma* is a very important factor. No doubt of the existence of the causative connection between trauma and epileptic change can be admitted at present date. Numerous and reliable observations have made this quite evident. Thus: (*a*) those cases, more especially, in which the epileptic symptoms develop after recent injury. So far as our present evidence goes to show, the epileptic phenomena which follow injury are of two classes: one of these is of the Jacksonian type; the other is that of diffuse or generalised epileptic symptoms. The first of these are due to the local effect of the injury to the cortex cerebri, and are definitely relieved by removal of the depressed fragments, or the extravasated blood; or to the pressure which these had kept up on the brain as a whole; thus also in cases of concussion of the brain, where the symptoms subside on the successful removal of the consequences of such concussion. (*b*) Then we have a group of cases, in which epileptic attacks persist for a shorter or longer period after the date of the injury; as the result either of the local effect of the traumatic lesion on the cerebral cortex, or of the general effect on the brain. In the first of these divisions, we have the occurrence of epileptic seizures of the Jacksonian type; in the second, we have the development of diffuse epilepsy.

The first of these groups is by far the most instructive with regard to the mechanism and mode of development of epileptic changes. We usually have to reckon with a traumatic lesion of the skull; in the course of a number of years, or perhaps much earlier, cramps of certain groups of muscles begin to appear, which in succeeding attacks effect larger groups; and so on, till we have the development of complete epileptic seizures—and, eventually, even some implication of the intellectual powers. So long as the attacks are limited to individual muscle-groups, the intellect is unlikely to become seriously clouded, but the more extended the epileptic phenomena become, the more do psychopathic alterations manifest themselves; and, in the very severe cases, not merely do we meet with typical pareses, and paralyses of the muscle-groups affected, but we find the development of idiocy, which is notably a phenomenon of frequent occurrence in connection with genuine epilepsy.

In a large proportion of cases, the muscle-groups affected in the attacks of Jacksonian epilepsy, or the aura by which these are preceded, are those associated with the cortical centre subjacent to the scar or depression of the skull produced by the original injury; in a good many others, however, the results of the trauma are manifested in areas of the cortex at greater or less distances from the original centre of which the irritation led to the origin of the symptoms.

When we operate in those cases, we find, as a rule, conspicuous pathological alterations at the seat of the trauma; either an impression in the cortex, or sharply projecting fragment of bone; or œdema of the arachnoid which often envelops the cortex completely; or a cyst, or a porencephaly; or, in fine, encephalitic foci of inflammatory or necrotic processes, of which the extirpation is followed by permanent disappearance of the epileptic attacks.

In connection with these observations, three facts are noteworthy—

(*a*) The resulting epilepsy may develop a number of years after the original injury; a fact which significantly indicates that with a congenital predisposition to epileptic alterations a longer interval may be necessary.

(*b*) The gradual extension of epileptic spasm to the neighbouring muscle-groups; this clearly teaches us that the epileptic alterations, after first engaging a limited cortical area, extend circumferentially; till a diffuse epileptic structural change of the nerve-tissues has become established.

(*c*) The almost constant occurrence of anatomico-pathological changes indicate the development of inflammatory processes in the seat of the trauma, and extending to the adjacent bones, meninges, and brain substance; cysts, œdematous swellings of the arachnoid, endostoses, hyperostoses, encephalitic foci, &c.

Tillmann demonstrated the existence of these changes in 19 of 20 cases observed by himself, and I did in six cases out of seven of my own. In 267 cases of traumatic (circumscribed and diffuse, generalised) epilepsy, collected by Tillmann from the literature of the subject, 233 (87 per cent.) presented specimens of those various changes; the revelations of operative procedure were negative in 35 (13 per cent.) cases only. But one cannot help thinking that many of these cases originated at an earlier period, at a time when the sources were not sought so much for in the brain. Accordingly, we do not commit ourselves to a mistaken opinion in stating that in the great majority of cases of traumatic epilepsy there may be found pathological changes, for the most part of chronic inflammatory nature; which stand in causal relationship with the structural alterations promoted by the occurrence of the original injury.

To the demonstration of this causal nexus luminous evidence has been contributed both by experimental research on animals and by the results of operative surgery. In the case of animals, epilepsy supervenes only when operations on the brain are followed by inflammatory processes; it never occurs when the operation wound heals by first intention (Tillmann). Then, with regard to the results of surgical procedure, it is an old experience that the operative procedures in cases of traumatic epilepsy lead to the most successful results in those cases in which pathological changes are found, and their products removed; while, in those in which the findings in the skull and brain are negative, they frequently produce but little improvement.

The clinical experiences of traumatic epilepsy which have hitherto been collected, and, in no less degree, the experimental results, lead to this conclusion; the gradual genesis and expansion of epilepsy, which coincide with the development of the chronic inflammatory changes in the skull and brain, on the one part, and the artificial results of operative procedure and experimental research, on the other, fully support the view that the various pathological findings in traumatic epilepsy stand in cause-and-effect relationship with the post-traumatic epileptic phenomena. Those changes develop in the cortical centres originally, or spread thereunto from a distant seat of injury, by successive steps; and, finally, under conditions still inexplicable, the first seizure takes place, by the occurrence of which the previously latent epileptic changes become manifest.

By this determination of a causal relationship between the pathological findings and the post-traumatic alterations, the surgical treatment of traumatic epilepsy becomes established on a scientific basis. By the same influence, traumatic epilepsy comes to be ranged in the group of so-called *symptomatic*, or secondary, or *organic epilepsy;* in which we had already included, and for corresponding reasons, those cases of epilepsy dependent on various pathological processes: new growths, granulation tumours, cysts, &c. Thus have the clinical symptoms, the pathological substratum, and the artificial results of operative interference, all combined in their respective departments to place the surgical therapy of this disease on a sound basis; and all the more so as the results contrast so forcibly with the disappointing ones obtained by medicinal agents in the treatment of so many forms of genuine epilepsy.

On the other hand, we have also to consider another large class of cases of epilepsy; those which are known as *idiopathic* or *genuine.* In respect to these, the dogma has hitherto held good, that epileptic phenomena are not genetically based upon pathological changes in the nerve-tissues and their environment. Many authorities would, indeed, claim a pathological substratum in cases of genuine epilepsy, but the structural alterations discovered were so insignificant and so variable that no certain conclusion could be drawn regarding their association with epilepsy. Nevertheless, the endeavours have continued to be still further extended, with the object of establishing the association of cause and effect in the alterations found in cases of "genuine" epilepsy. In this direction they are led by the clinical phenomena, which quite significantly indicate the fact that there exists no fundamental distinction between the clinical features of *symptomatic* and of *genuine* epilepsy.

With regard to symptomatic epilepsy, it is characteristic of the Jacksonian type of cortical epilepsy that the various post-epileptic alterations in the sensory and motorial zones tend to assume a more or less chronic character. Those changes, as a rule, are localised in the areas which determine the onset of the attacks in typical cases; and a sensory or motor aura often emanates from the locality. At the beginning of the development of symptomatic epilepsy, the sensorium appears to be unaltered; consciousness, as a rule, comes to be affected only at a later stage; when the convulsions have extended to a greater or less portion of the trunk, or the epileptic attacks have come to be universally diffused throughout the muscular system. Psychopathic post-epileptic alterations are decidedly rare of occurrence in cases of organic epilepsy.

Accordingly, in cases of *genuine* epilepsy we are presented with the following typical picture: after a prodromal aura, or without the occurrence of such, there is loss of consciousness and muscular spasm; which may be universally diffused from the outset, or be localised at first, and then extend, without any regularity of procedure, to other muscle-groups; and rapidly culminate in generalised convulsions. Permanent post-epileptic alterations of the sensory and motor areas do not develop; or at most we find but moderate and very transitory symptoms of exhaustion (*Erschöpfungssymptome* of Binswanger). A solitary exception must be admitted as regards *aphasia,* which appears pretty frequently, and persists a considerable time after the attacks in a good many cases. And not less frequent are various psychopathic symptoms, which successively develop in cases of *genuine* epilepsy. Many authorities, indeed, regard these symptoms, and also aphasia, as important indications of the presence of *genuine* epilepsy, as distinguished from the *symptomatic* variety.

Besides those typical forms of *genuine* and *organic* epilepsy, we have to deal with the very frequent occurrence of transitional varieties, which represent intermediate stages between the two great group divisions. Thus it is by no means rare to find in cases of *symptomatic* epilepsy that the circumscribed convulsions of an attack proceed to become general. In cases of long standing, psychopathic phenomena appear too, and not infrequently, even passing into idiocy; and we find, indeed, that the aphasia which is by many regarded as a typical symptom of *genuine* epilepsy also occurs in cases of the *organic* group; a significant instance of this will be hereafter referred to. On the other hand, we not infrequently observe cases of *genuine* epilepsy which lean strongly towards the Jacksonian type of symptoms; beginning always, as in *organic* cases, with certain muscle-groups, and then proceeding to the neighbouring ones; then again, permanent post-epileptic changes are not infrequent; they are usually, indeed, but slight, and may be easily overlooked when not specially sought for; but it is not rare to meet with significant alterations of hemiplegic nature, such as: muscular atrophy, dissimilar innervation of the two sides of the tongue, imperfect attempt at mimicry, &c.

The typical forms of one variety of epilepsy, and also those of the transitional specimens, give significant indications of the fact that from the symptomatic standpoint no principal dividing line can be drawn between the two great types of epilepsy; and that the distinctions which display themselves in the typical forms are but the expression of the more or less advanced epileptic changes of structure, up to the date of onset of the attack. As regards the *organic* form, the association is with a pathological substratum; accordingly it is but logical, when we grant the existence of a pathological substratum in the *idiopathic* type, to admit that we are not fully acquainted with its limits. This suggestion finds fairly abundant corroboration, not only in the ætiological influences, but also in the anatomico-pathological alterations found in cases of idiopathic epilepsy. Apart from the fact that so many cases of apparently *genuine* epilepsy have proved to be of *organic* origin (tumour, abscess), either in the course of their progress or by the revelations of the autopsy, it is definitely recognised now that a tumour may in many cases be a cause of the "genuine" type of attack. Friedrich found traces of injury on the shaven heads of more than half the cases of epilepsy he met with; and he believes, accordingly, that the trauma is the originating force in the genesis of epileptic alterations much more frequently than has hitherto been believed. It is often a matter of an accidental injury in early life, which is remembered by neither parents nor patient; or an accident of parturition; &c. Other authorities (Pierre-Marie, Freud, Zappert, Krausen, &c.) suggest that another ætiological factor which has often been overlooked is the occurrence of *acute encephalitis* in childhood. Apparently, cases of epilepsy which supervene during childhood after acute infectious diseases (typhus, scarlatina), are the result of abortive attacks of acute encephalitis; which had successfully escaped the notice of the physician as well as of the parents. Further evidence of the connection between encephalitis and epilepsy is afforded by the records of the occurrence of acute encephalitis in children—according to Weil, 75 per cent. of his 35 cases of encephalitis were followed by epilepsy—and, on the other hand, we have the occurrence of slight paresis; and the atrophy of the muscles of the limbs, and of the muscles of mimetic expression, to which I have already referred. According to Weil, too, syphilis, hydrocephalus, and diffuse hyperostosis of the cranial bones are among the ætiological factors accountable for the appearance of epilepsy.

In view of the fact that such factors are to be estimated in the production of epilepsy, we have obviously to recognise an ætiological connection between the *organic* and *idiopathic* types of the affection. But unfortunately the anatomical findings are not yet so numerous as to enable me to establish clearly the identity of the varieties of epilepsy—either from the clinical, ætiological, or pathological standpoint. Numerous writers (*e.g.*, Chaslin, Alzheimer, Rendori, &c.) have sufficiently studied the subject of *genuine* epilepsy. According to their results, structural changes appear in more than half of the cases; some distinctly macroscopic, and others histological only.

Apart from the discovery of cysts in many cases of the Jacksonian type, which unquestionably belonged to the group of *organic* epilepsy, there have been very frequently found in those of the generalised, *genuine* form of epilepsy: œdema; thickening or cicatrisation of the cerebral meninges; overgrowths of the latter; and, in rare cases, porencephaly; while in a good many instances there were developmental anomalies of the skull or brain, or both; asymmetry of the convolutions, and of the base of the skull; or microgyria.

Histologically recognisable have been endarteritic and arteriosclerotic changes, sometimes diffuse, and enveloping sclerotic processes of the grey and white matter of the brain; pachymeningitis; leptomeningitis; encephalitic foci; &c. The sclerotic areas involved appear to have been variously distributed in the grey matter; in many cases, the foci of sclerosis displayed changes of a trophic character; and, in others, of hypertrophic, or tuberose. The observations of Alzheimer are interesting; he found at intervals a distinct gliosis spreading inwards, while outside were alterations of evidently chronic character; and, in a case of *status epilepticus,* he discovered acute regressive changes in the neuroglia cells, destruction of axis-cylinder fibres, &c.

These findings furnish evidence in favour of the view that cases of ordinary, as well as those of *organic* epilepsy have an anatomical basis; and that this disease may, accordingly, be regarded as a chronic disease of the brain, accompanied by anatomical changes of varying quality and extent (Weber). And, although it cannot be said that the conditions found up to the present have been so constant as to dissipate doubts regarding this view, there is good ground for hope that the histological findings of the future will, in combination with clinical experience and pathological observation, explain the various phenomena of genuine epilepsy.

Those acquisitions to our knowledge are undoubtedly of great value to practical surgery, for they give the practitioner a scientific basis for his surgical procedure; the reliability of the leadership cannot yet, however, be regarded as finally established. Accordingly, we must for the present continue to make, from the standpoint of surgical therapeusis, a distinction between the *organic* (*symptomatic*) cases of epilepsy, in which definite, macroscopically visible, structural causes can be demonstrated; and those in which the microscopic anatomical alterations are so minute that they have no determining influence on surgical procedure, and are still referred to as *genuine* (*idiopathic*). In the former class of cases, as already indicated, there exists a scientific foundation for surgical interference; while, in the latter group, surgical procedure must be based, partly on physiological acquisition of new facts, and partly on theoretical hypothesis and assumption.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Sydney Stephenson, S.O. Oxon. Subject: "The Treatment of Glaucoma, with Particular Reference to the Newer Operations."*

ORIGINAL PAPERS.

THE PATHOLOGY AND TREATMENT OF HALLUX VALGUS.

By A. S. BLUNDELL BANKART, M.Ch., F.R.C.S.,
Surgeon to the Royal National Orthopædic Hospital, &c.

HALLUX VALGUS, or outward deviation of the great toe at the metatarso-phalangeal joint is a common deformity the true pathology of which is not generally recognised. It is commonly attributed to the use of narrow or pointed boots and shoes and is supposed to be the direct result of pressure against the inner side of the toe. Such ill-fitting footwear is worn by a great many persons and this explanation appears at first sight so simple and obvious that few have questioned it.

But there are many cases which are difficult or impossible to explain on the "boot theory."

Hallux valgus is said to have occurred in individuals who have never worn boots or shoes, and it certainly does occur frequently in those whose boots are broad and give ample room for the toes. It is easy to see how a narrow pointed boot may push the great toe outwards to a certain extent but why should the deformity increase when the toe has passed the line of the inner border of the boot? How can any boot push the toe right across until it lies almost at right-angles to the long axis of the foot, as it may do in a severe case of the deformity? Again, there are cases in which hallux valgus is present on one side only, the other great toe being in its normal position; and at least one case has been recorded in which there was hallux valgus on one side and hallux varus, or inward deviation of the great toe, on the other. Such cases cannot be explained on the theory of boot-pressure.

Indeed, the part played by boots and shoes in hallux valgus has been much exaggerated. In the vast majority of cases the deformity has little to do directly with the footwear, but is the direct result of flat-foot.

Hallux valgus is almost invariably accompanied by flat-foot. Indeed, most of the cases of slight or moderate deformity apply for treatment of the foot, and not on account of the toe; and where the chief complaint is of the toe, flat-foot, if looked for, can be found in nearly every case—usually it is well-marked. So constant is this association, that hallux valgus is commonly given as one of the causes of flat-foot, whereas the converse is the truth—hallux valgus is the result and not the cause of flat-foot.

It is obvious that when a curve or an arch is straightened out, the distance between its extremities is increased. So in flat-foot, when the arch of the foot is flattened out, the distance between its points of support is increased—in other words, the foot is lengthened on its inner side. One result of this is that a great tension is thrown upon all those muscles whose points of origin and insertion are moved further apart. Pain in the calf and up the front of the leg in many cases bears witness to this tension on the muscles whose tendons pass into the foot on the inner side.

Now, the proximal phalanx of the great toe articulates by a shallow concavity with the large rounded head of the first metatarsal bone. The articular surface of the metatarsal is more extensive in all directions than that of the phalanx, so as to allow free movement of the joint in flexion, extension and from side to side. Over the dorsal and plantar surfaces of the joint, the long extensor and flexor tendons, respectively, pass to the distal phalanx, so that the proximal phalanx is held as it were in a sling upon the head of the first metatarsal bone. Tension on these two tendons, when the toe is straight, pulls the phalanx backwards against the head of the metatarsal, and so long as the pull is straight in the long axis of the bones, it only increases the pressure on their articular surfaces, and does not produce any change in their relative positions. But should there be the slightest deviation of the phalanx to one side or the other, the tension will pull it round still further to that side and a deformity will result.

This is the common mode of development of hallux valgus. Sinking of the arch of the foot, with its accompanying elongation, throws a tremendous strain on the tendons which pass to the great toe. It is rarely that equilibrium is maintained with the toe straight; still more rarely does the toe deviate inwards in response to the pull upon it (though it may do so, as in the case of hallux varus already mentioned); in the vast majority of cases the toe is displaced outwards, and hallux valgus is the result.

But the long tendons are not alone concerned in the production of this deformity. Of the five short muscles attached to the great toe, the flexor brevis is inserted on both sides, and therefore does not cause lateral deviation; tension on the abductor hallucis tends to produce inward deviation unless this is prevented by the boot or by the greater pull of the abductors; the abductor obliquus, abductor transversus (if in action), and the innermost division of the extensor brevis digitorum, all tend to produce outward deviation of the phalanx. Almost invariably the outward pull preponderates over that in the opposite direction at least enough to give a start to the valgus deformity, which is then made good by the tension of the long tendons.

The tendon of the extensor longus hallucis can always be felt tightly contracted and displaced outwards, and it can generally be seen standing out under the skin. The long flexor tendon is too deeply placed to be felt externally, but at operation it also is found to be tightly contracted. Secondary shortening of the external lateral ligament still further fixes the deformity. On the inner side, the uncovered cartilage on the head of the metatarsal in time becomes atrophied, while the overgrowth of bone behind it forms a prominence exposed to friction and pressure, and this, with the bursa over it, is the chief source of annoyance to the patient.

Occasionally, as mentioned above, the great toe remains straight in spite of the tension on it, the factors which make for abduction and adduction being equally balanced. We then have a condition in which the great toe is held stiffly in the straight position with the intra-articular pressure greatly increased. In such cases, on account of the increased pressure, and possibly also on account of increased liability to injury, changes take place in the cartilages of the joint, which become atrophied and irregular at the centre, and irregularly hypertrophied at the periphery—osteoarthritic changes, in fact, which permanently destroy the mobility of the joint and fix it in the straight position. This condition is called Hallux Rigidus, and it also is a direct result of flat-foot, which is invariably present.

Lastly, it sometimes happens that in the development of hallux rigidus in the manner just described, the pull on the plantar aspect of the joint exceeds that on the dorsal side, or *vice versa*. In the one case the toe becomes fixed in a moderately flexed position—Hallux (Rigidus) Flexus; in the other it is extended—Hallux (Rigidus) Erectus.

Treatment.

The treatment of hallux valgus should include that of the accompanying flat-foot. Slight cases do not complain of the toe, but of the foot, and in these cases, cure of the flat-foot removes the condition which gives rise to hallux valgus. When relief is sought for hallux valgus itself, the deformity is always well-marked, and, unless the treatment is to be merely palliative, some operation will be required to correct it.

An operation which is very frequently performed for this condition is excision of the head of the first metatarsal bone. This operation is a bad one, though it often gives great relief. It is bad because it removes one of the chief supports of the arch of the foot, so that the affection of the toe may be cured, but at the expense of the foot. This objection has been met by the argument that while the head of the first metatarsal is an important bony point in the normal foot, it loses its importance as a support of the arch when the foot is flat, and therefore its removal does not matter. But the aim of treatment should be to restore the arch of the foot as well as to straighten the toe. Removal of the whole metatarsal head permanently destroys the arch, it makes the subsequent treatment of the flat-foot impossible, and greatly impairs the usefulness of the foot.

But often, when the patient has suffered much from pressure on the sensitive enlarged metatarsal head, its removal gives immediate relief—a relief which overshadows all his subsequent disability. He has long ago forgotten what it is like to have a normal foot, and the contrast between the fixed pain before, and its absence after operation, is enough to satisfy him. On the other hand, in more recent cases, in those who have not suffered so much, and especially in those who wish to return to some active occupation, the relief is not always so striking, and the patient experiences to the full the disability of a permanently broken-down arch. If enough bone is removed, the toe is movable, but it is a poor stunted thing, very apt to stick up, and of very little use to the patient; if only a part of the head is removed, the joint becomes stiff and painful unless special means are taken to prevent it. This operation should, therefore, be reserved for exceptional cases in which the flat-foot is confirmed and hopeless, and the toe-joint is already stiff and disorganised, and in these cases some form of arthroplasty is the operation of choice.

Another operation which is very commonly done for hallux valgus. consists of excising the bursa, chiselling off the bony prominence on the inner side of the head of the metatarsal, and then forcibly straightening the toe after dividing the contracted ligaments on the outer side of the joint. The fault of this operation is that it is incomplete. The long extensor tendon is often divided, because it is in evidence. but seldom if ever is any attempt made to divide systematically all the contracted tendons. The result is that the toe is brought straight at the time of operation, but the tendency to relapse is very great; constant attention is required afterwards to prevent it; and when this ceases, the deformity returns.

An extension of this operation is clearly indicated by the pathology of hallux valgus. The operation which I have performed in all ordinary cases for some time past is as follows:—A curved incision is made over the enlarged metatarsal head, and a flap is turned down on the inner side, so that by retraction both the dorsal and plantar surfaces of the joint can be exposed. The tendon of the extensor longus hallucis is then divided, after which the innermost tendon of the extensor brevis digitorum is exposed and cut across. Next, the tendon of the flexor longus hallucis is sought in the groove beneath the metatarsal head and being hooked out, it also is cut across; this tendon is always found tightly contracted, and its division effects an obvious relief of tension on the great toe. A flap of bursa and joint-capsule is now turned forwards attached to the inner side of the base of the phalanx. The rest of the bursa is excised, and the prominent overgrowth of bone on the inner side of the metatarsal head is chiselled off, leaving a smooth rounded surface. The toe is now forcibly abducted (inwards), tearing or stretching the soft parts on the outer side of the joint. As a rule this is sufficient to bring about over-correction of the displacement without any tendency for the toe to spring back, but sometimes it is necessary to divide the external ligament or the tendons of the short muscles inserted into the outer side of the phalanx. The former may be divided from within the joint; the latter should be exposed and identified by retracting the flap before they are divided. The toe being now slightly abducted (inwards), the flap of capsule which has been left attached to the inner side of the phalanx is sewn back with stout catgut to the soft parts on the inner aspect of the metatarsal bone—*i.e.*, to the abductor hallucis. Finally, the skin flap is replaced and sutured without drainage. This operation has given excellent results in a number of cases. By systematic division of the contracted soft parts, especially the two extensor and the long flexor tendons, the tendency to outward displacement of the toe is entirely overcome. The metatarso-phalangeal joint is preserved and retains its mobility; and by suturing back the flap of fibrous tissue attached to the inner side of the phalanx an internal lateral ligament is formed which retains the toe in position. In some cases I have inserted the long extensor and flexor tendons into the head of the metatarsal bone in order to preserve their action, but I do not think this step is really necessary; it slightly prolongs the operation and I have not seen any ill-effects from their simple division.

After the operation proper boots must be worn and treatment must be directed to the flat-foot which is invariably present.

FOOT AND MOUTH DISEASE IN MAN—APHTHOUS FEVER. (*a*)

By C. M. O'BRIEN, M.D., L.R.C.P.,

Physician to City Hospital for Diseases of Skin and Cancer, Dublin; Honorary Member of the Dermatological Society of France; Fellow of the Medical Society of London.

Amidst the grey routine of my daily grind it has ever been my wont to bring under notice of the profession things within my purview which appeared to me of interest to it. I am happy in the belief that my humble efforts in this respect have been fully justified by reason of the full, free and unfettered discussion which they invoked on each occasion. Actuated by this spirit, I bring the report of this case before you to-night, in order to place on record notes of a cutaneous affection which falls to the lot of few to meet.

The epidemic of foot and mouth disease in cattle which swept this land from shore to shore in 1912 and which created such financial havoc and black despair amongst a large portion of our population enables me to relate my only experience of this malady as it affects mankind. Although the statement at first sight may seem somewhat paradoxical, it is, nevertheless, true to say that perhaps the most interesting feature associated with foot and mouth disease in man is the paucity of its bacteriological literature, and in search of this literature the point above all others which impressed me most is, that in an age like the present, of modernism and medical research, how little, after all, we are helped towards a positive diagnosis in this as in many other cutaneous affections by other than those senses which are the heritage common to all and which served Æsculapius in such good stead long before the death of Grecian priest-craft and even the dawn of medical history. It would appear that the first reliable record of foot and mouth disease in man was made in 1695, by Valentin, of Hesse. In 1834 three Continental veterinary surgeons named Hertwig, Mann, and Villain, while investigating the disease in cattle, wished to know if it were communicable to human beings, and as an experiment voluntarily drank a quart each of the milk from a cow suffering from the infection. On the second day Hertwig suffered from fever, headache, and itching of the hands and fingers. Five days later vesicles appeared on the fingers, hands, tongue, cheek, and lips. Mann and Villain developed vesicles on the buccal mucosa. In 1896, during an outbreak of foot and mouth disease in Berlin, several instances of its spread to man were reported, and unhesitatingly confirmed by Virchow, after an investigation which for minuteness and completeness of detail could not fail to influence the most sceptical.

A child fed on milk of diseased cows had chill and fever with gastric disturbances and later an eruption of vesicles on lips, tongue, and the clefts between fingers and toes. A shepherd infected himself by holding in his mouth the knife with which he had pared the diseased feet of sheep. In 1883, Sir Charles Cameron, C.B., M.D., Chief Medical Officer of Health for Dublin, during the epidemic in this country of foot and mouth disease in cattle had under his care a man who contracted the disease through direct inoculation. He presented a rash on both feet and hands which developed into vesicles later. The throat, lips, and mucous membranes had also distinct vesicles. About the same time Sir Clifford Allbutt saw the buccal eruption in three children during an epidemic of foot and mouth disease in Yorkshire.

Cases of infection through butter made from infected milk are on record, of which the following is a good illustration:—

On November 18th, 1890, a veterinary student in Berlin had sent to him by his brother-in-law a packet of fresh butter made from the milk of cows suffering from foot and mouth disease. On the following day he ate some of the butter for the first time. During the next night he was feverish, and on the morning of the 20th he found his lower lip red, swollen, and covered with vesicles which were itchy. Later the vesicles spread to the buccal mucosa.

Similarly, Schneider gives cases caused by infected cheese, and Friedberger cases from virulent buttermilk. Instances of infection by inoculation have been observed, of which the following is perhaps the most interesting and instructive, and as it presents many points in its clinical history which resemble the subject of my paper I am induced to give full details as they appear in the *Veterinarian*, 1831:—

The patient was a farmer who had injured one of his fingers in drenching a cow suffering from foot and mouth disease. The wound took on an unhealthy action, and after some days he was taken ill with a cold shivering fit. This occurred in the evening, and by the following morning the cold fit had been succeeded by fever. Twenty-four hours later vesicles formed on the gums and tongue.

Instances of transmission of the virus of foot and mouth disease from lower animals

---

(*a*) A paper read before the Section of Medicine, Royal Academy of Medicine in Ireland, January 31, 1913.

to man both by inoculation and otherwise could be further multiplied if time allowed or necessity demanded, but I feel convinced there are few if any serious thinkers amongst us to-day who entertain much doubt upon this particular point. For myself I candidly own that if at any time in my career I entertained the least doubt as to the transmission of foot and mouth disease from lower animals to man that doubt is dissipated for all time by the undermentioned case, notes of which *tout ensemble* constitute a clinical picture not easily counterfeited.

Case :—G. J. B. consulted me in my study on August 12th, 1912. He now permits me to publish the following :—

Veterinary Inspector, Irish Agricultural Department, M.R.C.V.S., æt. 35, married. Family history—unimportant. Personal history—of temperate habits ; had scarlet fever at the age of ten. Otherwise he always enjoyed very good health. On July 9th, 1912, while in discharge of his duty as Veterinary Inspector to the Irish Agricultural Department, he was bitten by a sheep on the index finger of the left hand while examining the beast for suspected foot and mouth disease on an infected farm at Swords, co. Dublin. Having applied an antiseptic dressing to the wounded finger and used a thin rubber finger-stall as an additional protection, he continued his daily examinations without intermission, not anticipating any serious results. About three weeks later the wound appeared to form an abscess to which the patient applied an abscess knife, with every antiseptic precaution. There was no pus found ; the local pain and tenderness continued and the wound did not heal. As his colleagues of the department were all fully occupied coping with the outbreak, and as his services as a result were badly needed, he declined to lie up. On the morning of August 11th, redness and swelling appeared on both hands and fingers, accompanied by great itching of the parts, with a few small raised white swellings like little lumps under the skin especially round the nails. By night time slight itching of the upper part of both feet, accompanied by a sensation of pin pricks in the soles, which became more pronounced when walking. He also complained of feeling out of sorts for a day or two previously. Bowels were confined ; slight headache was present, with loss of appetite and some colicky pains.

Having received the foregoing particulars I proceeded to examine the patient. A thick, well set up man, about 5 ft. 6 ins. in height, of exceptionally good muscular development. Rather younger in appearance than stated age. The fingers and dorsal aspect of both hands were markedly swollen and covered over with a dull, reddish, raised rash, which stopped short somewhat abruptly an inch above the wrists. Examining closely, immature vesicles were observed here and there over the surface of the rash, more especially in the clefts between the fingers and immediately above and around the finger nails. A sensation of great itching over this region was complained of. On removing the dressing of the injured finger, the edge of the wound gaped, and although no pus exuded on pressure, nevertheless it exhibited few signs of healing. There was no perceptible involvement of the lymphatic glands. Examination of the throat exhibited congestion of the fauces with some vesicles. Vesicles were also observable on the inside of the lips, gums, and side of the tongue. The latter appeared swollen and tender. Mastication, deglutition, and talking were painful. The saliva was increased and the voice less distinct than normal. The temperature registered in the mouth was just 100°, and never exceeded this during the entire illness. The urine was high coloured, of acid reaction, specific gravity 1020, sugar and albumin absent. The heart, lungs, and other organs appeared quite normal. The patient complained of increasing itchiness over the dorsal aspects of both feet, and excepting a slight redness above and inside both knees, no rash was perceptible on lower extremities at this stage. But there was a sensation of sharp pin-pricks over the soles of both feet, rendering locomotion troublesome. Knee-jerks were normal, ankle-clonus present.

Condition of patient on August 13th, 9.30 a.m :—Excepting the slight rash on inside of thighs, which has now entirely disappeared, all the previous symptoms are more pronounced. Vesicles fully formed about the size of peas on lips, tongue, and fauces. Saliva trickles from the mouth. Swallowing and speaking more painful, while in addition the dorsal aspects of both feet present a rash precisely similar to that previously described on hands, the rash extending to ankles and stopping short at this point on both feet. Vesicles in process of formation are also observable between the clefts of the toes and around the toe-nails. Temperature 99.5°.

The same evening the patient was seen by Sir Charles Cameron,. CB., M.D., in consultation with me. Vesicles were present on the throat, the side of the tongue, the fauces, and inside of the lips. The contents of vesicles which in the early stage were clear had now become somewhat turbid. In some instances the vesicles on mucous membranes had coalesced and ruptured, leaving small shallow ulcers with dark red base. Sir Charles Cameron, after a careful examination of the patient, said the case presented symptoms precisely similar to a previous case of foot and mouth disease in man which he met with in the epidemic of 1883. Saliva continued to trickle from the patient, and the painful swallowing permitted now of liquid nourishment only. The progress of the case continued without alteration—the temperature remaining between 99° and 100°.

On August 15th the rash on the hands began to fade, the vesicles ruptured, and further vesication ceased, but the soreness of the throat and free flow of saliva continued for some days. On August 17th Sir Thomas Myles, F.R.C.S., saw the patient in consultation with Sir Charles Cameron and myself. This was the seventh day of the illness. Fresh vesicles had by this time ceased to appear, and only the remains of previous ones were in evidence on the throat, lips, and both feet. These with the copious saliva and difficult deglutition were the only data to guide us now. Sir Thomas Myles examined the patient's feet, throat, and hands very minutely. He also examined the wounded finger. He said that as a result of his examination, from all he had seen, and from the history given by the patient, he believed the case to be one of foot and mouth disease, but seeing it on the seventh day, after the acute attack, it was impossible for him at that stage of the illness positively to confirm the diagnosis.

It is agreed that neither sex nor age, race nor class, affords exemption from foot and mouth disease. It is also agreed, thanks to the research and logical deductions of Loeffler, that the bacillus, virus, or whatever it may be termed, which causes foot and mouth disease, is sufficiently small to allow of its passage through the finest pored porcelain filter and to elude the most powerful microscope. Like the biblical grain of mustard-seed, this virus or bacillus gives rise to results in man which have taught me the lesson derived from personal observation and experience, that apparently slight cases, if neglected, may lead to grave results. Whether these results depend on tissue changes effected by the direct action of the bacillus or its toxins, are questions still in the womb of time.

In conclusion I take this opportunity of expressing my indebtedness to Sir Charles Cameron. From all the literature within my reach (both local and foreign) bearing on this subject I think I am correct in saying that Sir Charles has the unique distinction of being, not only the only medical man in the United Kingdom, but the only medical man alive to-day who can speak from practical personal experience of two separate cases of foot and mouth disease in man due to direct inoculation from the lower animal, one so far back as thirty years ago, during the epidemic of 1883, the other which is the subject of the present paper. I am also indebted to Sir Thomas Myles, M.D., F.R.C.S., whose examination of the patient excludes any ambiguity in diagnosis which might arise from a surgical standpoint. I also thank Mr. T. T. O'Farrell, F.R.C.S., Bacteriologist to the City Skin Hospital and to St. Vincent's Hospital, for his examination of the epithelial *débris* and contents of vesicles, with negative results. My thanks are in an especial manner due to my former patient, Mr. George J. Bell, M.R.C.V.S., who in the cause of veterinary and medical science, permits me to bring before the Royal Academy of Medicine in Ireland, this case which is as far as I know the first published case of its kind in Great Britain.

TUBERCULOUS MENINGITIS IN ADULTS.

By GEO. A. CRACE-CALVERT, M.B.Lond., M.R.C.S., L.R.C.P.
Physician to the Vale of Clwyd Sanatorium.

This paper is based upon 7 cases of tuberculous meningitis occurring, during the past 11 years, in patients who had been, or were actually, at my sanatorium; and though some presented signs of tuberculoma in the early stages, all ultimately died of meningitis.

I have been able to find very little reference to the subject in the recent medical journals, but there is a paper by Dr. Warrington, read before the Association of British Physicians in 1910 and published in the *Lancet* of December 17th of that year, and I am indebted to that for some of my information.

Of all the forms in which tuberculosis manifests itself, tuberculous meningitis is undoubtedly the most fatal, whether in children or adults; and I can find very few records of cases of recovery, and I believe that they were all in children. Martin (a) gives 20 undoubted cases of recovery since 1894.

The disease is practically always secondary to tuberculous infection elsewhere, and perhaps most often to pulmonary tuberculosis, but it may occur as the terminal affection of tuberculous disease anywhere. Cases have been reported—especially in children—in which it was supposed to be primary infection; but in most of these a primary lesion has probably been overlooked, and might have been found in caseating bronchial, or other, glands, and, in fact, it has been asserted that the bronchial glands are always markedly affected.

Again, it may be part of a general miliary tuberculosis, the other evidences of which have been overlooked, because the meningeal symptoms develop so rapidly and at once monopolise the clinical picture. Horder, in his book on "Clinical Pathology," says that tuberculous meningitis inevitably means generalised tuberculosis; but in a more recent article (*a*) I see that he says that it may be more localised.

In the cases of which I have notes it has always been secondary to some lesion elsewhere; and out of 30 cases the primary lesion has been in the lungs in 23, in the lungs and larynx in 2, in the pleura in 2, and the other cases started from a chronic tuberculous cerebral tumour, and subacute tuberculous epididymitis with abscess formation.

In 3 of Dr. Warrington's cases no primary lesion could be detected during life in the lungs or elsewhere, and, as no post-mortem was made, no primary lesion is mentioned. In another there was a history of phthisis of ten years' duration; and in the last there was old apical disease, caseating bronchial glands, and a solitary caseous tubercle of the cerebellum.

Cornet (*b*) says that it may occur after such primary lesions as caries of the wrist, lupus, tuberculosis of the nose or generative organs; and also after trauma or operation. In the majority of cases it is of hæmatogenous origin, bacilli gaining direct access to the brain and meninges by the blood-vessels, owing to the breaking down of a primary focus; and in many cases it is possible to find tubercles directly in the blood-vessels, or nodular tuberculous enlargements may be found upon the smaller arteries, and many of these small tubercles in the perivascular sheath of the small arteries are in varying stages of caseation.

In addition to its origin from blood-vessels, it may also arise from infection along the lymphatics leading from neighbouring structures; and Cornet mentions cases which have followed on enucleation of the eye for tuberculosis of the iris, or directly from the same disease when enucleation was not permitted. And in the same way it may occur after tuberculous disease of the ear-bones or after postpharyngeal abscess.

Beattie (*c*) says that, in cases of meningitis of the spinal cord, the infection has most probably been conveyed from bronchial or mediastinal glands by way of the lymphatics.

Bridge (*d*) says that it does not occur often in cases of pulmonary tuberculosis, and Fowler and Godlee state, out of 531 cases of pulmonary tuberculosis occurring in Brompton Hospital in the three years 1892–94, only 18, or 3.3. per cent., developed meningitis; whilst West found it to occur in 1.5 per cent. of his own fatal cases. In about 520 cases in my own sanatorium during the past 11 years I know of 7 cases—though, of course, there may have been more that have not come to my knowledge—and of these, 4 have occurred in the last 15 months. This works out at about 1.5. per cent. From other sanatoria I have been able to collect 23 cases occurring in the last 13 years.

An interesting point, and one that it is desirable to elucidate as far as possible, is the question of the relationship—if any—between the administration of tuberculin and the incidence of meningitis. Some writers say that the disease may be due to the employment of tuberculin; but Cornet does not consider

that there is any proof of this, and says that amongst 420 patients to whom he has given tuberculin he has not had a case of meningitis. I have now given tuberculin to 106 cases, and 4 of these have developed meningitis. But of these 4, one had not had any tuberculin for over a year; another none for a month; whilst of the other 2 cases, one—a very bad laryngeal case—had only 4 doses, but the throat condition was so bad that the prognosis was hopeless to begin with, though the larynx was undoubtedly improved at first under tuberculin treatment; and the last, with tuberculous pleurisy and a raised temperature, was making great improvement and just beginning to get about when, after about 9 doses, he took much more exercise than he had been ordered, and began with headache.

Of course, one knows that tuberculin produces a focal reaction, and in this way might produce an extension of disease or a breaking down of a primary focus elsewhere, and thus set bacilli free, which might find their way to the meninges; or if solitary quiescent tubercles were already present in the brain, the focal reaction in them might light up meningitis. But, on the whole, even though one occasionally sees a lighting up of plumonary disease after the exhibition of tuberculin, it is nearly always confined to the lungs. And, on the other hand, one frequently sees a lighting up of the pulmonary disease without tuberculin being used. And, further, as in 25 out of 30 cases of which I have notes, tuberculin had not been used, I am inclined to think that it is only coincidence, and that there is no real connection between them.

In connection with the cases in which the primary lesion is in the lungs, there does not seem to be the slightest relation between the duration, extent, or degree of activity of the pulmonary disease and the probable occurrence of meningitis. It does not seem to matter what degree of arrest or apparent healing has taken place, the patient may still develop meningitis. Cases occur whilst the disease in the lungs is quite active though in none of my cases of really acute pulmonary disease did it develop; and here, of course, one cannot be altogether surprised if it did develop, especially if it is correct that tubercle bacilli are always in the blood. But, on the other hand, it occurs in patients who have, to all intents and purposes, quite recovered, and who have led an ordinary, active life for years. In only two of my cases was the disease at all active, and in most of the cases mentioned to me the disease in the lungs was fairly chronic.

With regard to the question of sex, Bonney states that the greater portion of his patients have been females, though he admits that it is more common in males. Of my own cases 6 occurred in males; and of cases from other sanatoria 26 occurred in males and 4 in females.

It is perhaps a little difficult to explain the reason why so many males are affected, but it may possibly be due to the fact that male patients, as a rule, worry much more about their illness, because so much depends upon their quick return to health or actual recovery.

Bonney states that irritable, highly excitable people develop meningitis more frequently than those of a phlegmatic temperament, and he goes on to say that people of a sunny, cheerful disposition are less prone to it; but this is not altogether borne out by my cases, as three at least were of a very cheerful disposition.

The predominance of male patients is not explained by the possible more frequent incidence of pulmonary tuberculosis in males, as if all ages be taken there is practically no difference between the sexes as regards liability to death. After the thirty-fifth year the male rate of death from pulmonary tuberculosis is higher than the female, but this does not altogether account for the disparity.

A history of excessive indulgence in alcohol has also been stated to be frequently associated with the subsequent development of tuberculous meningitis; but in my limited experience this type of case has never developed it, but has died as a result of the pulmonary disease being of a rather malignant type, perhaps before any secondary infection or focus could develop (*a*).

Bonney has never seen it amongst Jews, Negroes, or Swedes.

It is seldom seen at ages over 50. The ages in my cases varied between 29 and 44; whilst Dr. Warrington's cases were between 26 and 45, though he states that Jaquet reported 7 cases in which the ages ranged from 41 to 68. So that it rather seems as if the period between 30 and 45 is that in which a patient may possibly develop the disease; whilst at ages over 50 there may be lessened opportunities of extension of the pulmonary processes, or the primary lesion may be firmly scarred or calcified by this time, or the patient's immunity may be such that no spreading of the disease is possible.

Symptoms and Signs.—The classical symptoms and signs in children may be briefly stated as headache, vomiting, fever, intolerance of light, together with optic neuritis and Kernig's sign; and of these, headache is usually well marked from the beginning. But in adults the symptoms of the onset of the disease are very insidious and diverse, though occasionally it is quite abrupt. In some cases localising symptoms or signs occur, and headache or intolerable pain in the head and neck develop at once; whilst in others subjective symptoms are the first thing noticed, and the objective signs only follow at a later period and leave no doubt as to the diagnosis. The most frequent mode of onset seems to be the non-acute type, where odd subjective symptoms gradually show themselves, and may persist for a few days or even weeks before any definite localising signs of meningitis present themselves. These subjective symptoms may be such things as loss of appetite, irregularity of the bowels, general weakness, sleeplessness, loss of control of the sphincters, change of manner or disposition, mental irresponsibility, vague pains in the head, excitement or mild hysteria or trigeminal neuralgia. A patient who is naturally reserved may become rather foolish and laugh a good deal, whilst another may become quieter than usual. In other cases there may be temporary periods of rambling discourse or wandering delirium, from which the patient can be roused by questioning, though the answers may at first be a little confused. Lastly, there may be tremor or twitching of the extremities, or gradually increasing paralysis of the muscles of a limb or of the eye; but, as a rule ocular and motor signs do not develop until after the subjective symptoms have become fairly well defined.

Thus we see that the onset of tuberculous meningitis may be very insidious and take place in a multitude of ways. But though the onset may be varied or prolonged, sooner or later severe persistent headache develops. This headache is usually frontal, but may be at the back of the head and extend down into the neck, or it may start locally and then radiate over the rest of the head. With the headache there is usually more or less fever—though this is sometimes absent.

Vomiting does not seem to be so constant a symptom as in children, and in only two of my cases was it present to any degree; in one near the beginning of the illness, and in another near the end. It must, of course, be independent of food to be of use as a sign of disease.

Constipation is usually marked, though to a certain extent it may be due to morphia, if this has been given for the relief of pain.

Retention of urine frequently occurs, but both this and constipation are often replaced at a later period by loss of control of the sphincters. One patient lost control of the sphincters quite early.

The abdomen usually becomes retracted. Hiccough may be present, and in one case was intense during the last three days of life.

Respiration is often slow and shallow, but towards the end may become Cheyne-Stokes in character, or

---

(*a*) During the discussion which followed it was stated that tuberculous meningitis did not occur in the insane, though chronic pulmonary tuberculosis was very common, and massive tubercle was not infrequent.

become rapid and irregular without any local pulmonary condition to account for it.

The pulse at first is usually quickened and irregular, and may remain so all through; but sometimes it is slow and of high tension.

Intolerance of light and noise is usually present early, especially when the headache is severe.

Tache cerebrale was only present in one of my cases.

Optic neuritis seems to be a very variable sign, and was absent in at least four of my cases, and in four out of five of Dr. Warrington's cases. Other ocular symptoms are irregularity of the pupils, strabismus, and paralysis of any or all the ocular muscles; but none occurred in my patients. Kernig's sign is usually present, but was absent in three of Dr. Warrington's cases, and also in two of mine, where its presence would have been a great help in diagnosis.

There is often pain or stiffness in the neck muscles, which may lead to a certain degree of retraction of the head; and this pain may also extend to the muscles of the back, especially if the meninges of the cord are affected as well.

In one case intense cyanosis and dyspnœa were present, but were probably due to miliary tuberculosis of the lungs.

Whatever symptoms are present, the headache is usually the most marked, and persists until the patient becomes apathetic and finally comatose, when there can be a certain amount of moaning, or convulsions may develop, and death ensues a few days later. In my experience it has been the usual thing for a patient to become comatose several days before the end, and then, after a day or two, to recover consciousness for a day or longer—and even to appear quite rational, as though actual recovery were going to take place. But after this short recovery, coma comes on again, and death takes place a day or two later. But cases have been recorded where there were actually periods of improvement, during which the temperature returned to normal and pulse and respiration became regular. In one (*a*) there was apparent recovery for a month, during which the fever and subjective symptoms were absent; and then a second attack occurred, and terminated the patient's life in three weeks—four months after the onset of the first symptoms. In another the attack lasted four days, and was followed by a period of well-being and increased strength lasting two months. This was followed by another attack lasting six days, and after an interval of twelve days, by another lasting five days. Finally, after a few more days of freedom from symptoms, the disease ended fatally at the end of five weeks.

These remissions may perhaps be explained as follows. If the rupture of a tuberculous focus has occurred, abundant toxins and comparatively few bacilli may be poured out. Then the toxins may be excreted from the body in a few days, provided that the rupture becomes covered with a fibrin coagulum, and so the symptoms may abate, for any tubercles which are still in an early stage of development cannot manufacture enough toxin to cause symptoms. Next the tubercles increase in size, a fresh supply of toxins or bacilli is formed, and symptoms again appear. Or, again, the presence of toxins may excite the formation of a supply of antitoxin sufficient to neutralise them temporarily, only sooner or later to be flooded by a further development of toxins. This process may perhaps be helped by the pressure on the brain causing a smaller supply of blood to the tubercles.

Diagnosis.—The occurrence of severe persistent headache during the course of pulmonary tuberculosis, or of practically any form of tuberculosis, is always very suggestive of the onset of meningitis, a[illegible] neuritis or Kernig's sign be present in addition, the diagnosis is pretty certain. Again, the presence of odd and unaccountable mental symptoms should raise a suspicion of the disease.

In any case—especially doubtful ones—the fluid obtained by lumbar puncture will nearly always give the correct diagnosis. In these cases the fluid is usually increased in quantity, and so under more or less pressure, slightly turbid, or, as in two of my cases, quite clear, it contains a small amount of albumen—more than in health, and an excess of lymphocytes, and in 80 per cent. tubercle bacilli are found. It often possesses slight reducing power.

As illustrating the difficulty of diagnosis in some cases I may perhaps give details of a few cases.

A man æt. 36 developed pleurisy at the right base somewhat insidiously in August, 1911. No pulmonary disease was detected then. It cleared up, but returned in May of this year (1912), when he was sent to me. Signs of old pleurisy were present and nothing could be heard in the lungs because of the thickened pleura but I found one or two tubercle bacilli in the sputum after a prolonged search. The signs cleared a good deal, but the temperature remained somewhat raised, and at the end of six weeks I began giving him tuberculin. By the middle of August (six weeks later) his temperature had been normal for 10 days, and I gave him short walks; but, unfortunately, he felt so well that on three occasions he did about twice as much as I had intended, and next day, on August 18th, he did not feel so well and stayed in bed. During the next few days his temperature slowly rose, and by the 22nd he had a very severe headache, which was relieved by bromo-chloral. It came on again next day, and was again relieved by bromo-chloral.

The pain was now chiefly supra-orbital on the left side, and Dr. Hill-Abram saw him on August 24th, as I was suspicious of meningitis, and he said that beyond the headache there was no other symptom or sign pointing to meningitis, though lumbar puncture was not done, as we did not wish to give a general anæsthetic, and did not think it wise to do it without, as he was a very highly strung man. We hoped that it would turn out to be neuralgia or possibly sinusitis. Next day he would not take food unless fed, and on the 26th he was seen by a dentist, who could not find any cause for neuralgia. For 3 more days the headache was very severe, and there was intolerance of light and occasionally very slight disturbance of speech, though he was usually quite rational and answered when spoken to. Dr. Horder saw him on August 30th, and said that without lumbar puncture he could only be very suspicious of tuberculoma, as practically no signs were present, though there had been vomiting once or twice, but not clearly independent of food. Lumbar puncture was done, under an anæsthetic, and an increased quantity of fluid was found under only slight pressure, upon which Dr. Horder reported that it showed an increase of cells, a globulin ring, rather more albumen than usual, but no tubercle bacilli, conditions which would be produced by a patch of meningitis or a local deposit of tubercle. The leucocyte count was 13,000, which excluded generalised tuberculosis. He died 10 days later, after convulsions and coma had supervened.

A man with chronic, more or less healed, disease of the lungs had been leading an active life for nearly 3 years when he got a severe cold with neuralgic pains in the head, and only a fortnight later did headache, vomiting, and constipation appear, and he died 17 days later.

In another, 6 months after leaving the sanatorium very severe pains in the back and head came on, and were supposed to be rheumatic; and it was not until nearly a month later that slight disturbance of speech was noted and he become delirious.

Another, who had not been feeling well for some time and had taken more alcohol than was good for him, was suddenly seized with intense headache, and was first supposed to have influenza and then delirium tremens, as he wandered a good deal at night and was violent on some occasions. Coma followed and he died about 9 days after the onset of headache.

Another was up and walking about for nearly a fortnight with bad headache, which was supposed to be due to biliousness.

In another, headache was the first sign, and was continuous but not so severe as to keep the patient awake

---

(*a*) *Nothnagel's Encyclopædia* vol. "Tuberculosis," p. 670.

at night, and often when talking to the doctor the pain nearly disappeared, only to return with more severity afterwards. Temperature varied from 100° up to 102° or 103°, but no other signs developed for nearly two weeks, when there was some vomiting followed by coma.

Prognosis.—In adults the disease seems to be fatal invariably; and though cases of recovery are reported in children, I have failed to find any in adults. The duration is variable, and death may take place in a few days (9 days in one of my cases), or it may be delayed for several weeks (in another case 6 weeks), but probably most cases end within 3 weeks from the onset. Dr. Jane Walker has reported a case to me where an attack began on November 11th with vomiting, headache, and prostration, which stopped after a few days. Some weeks later the symptoms returned, and death took place on January 20th, *i.e.*, 10 weeks after onset.

Treatment.—This up to the present seems to have been mainly symptomatic. Practically nothing in the way of drugs relieves the headache except morphia. At first a mixture of bromide and chloral may do so, and antipyrin may give temporary relief; a dose of calomel often gives temporary relief to the headache. Iodides may be tried with a view to causing absorption of the tubercles. In a child of 6, inunctions of iodoform (grs. 15 to the ounce of vaseline) every 8 hours brought about recovery,(*a*) and in a small boy (*b*) potassium chlorate produced immediate improvement and ultimate recovery, and these methods of treatment might be tried in adults. Wet cupping over the parietal bosses will often restore the patient to consciousness temporarily (MacAlister). Inunctions of mercury may do good.

The removal of cerebro-spinal fluid by lumbar puncture will often give temporary relief, but in neither of my 2 cases in which it was performed was there any change. However, in children several cases of complete recovery have been reported, and one in particular, mentioned by Bonney,(*c*) in a girl of 16 after 2 months' illness. Lumbar puncture was performed daily during the first two weeks, and altogether 24 times, during which a total of 574 c.c. of cerebro-spinal fluid containing tubercle bacilli was removed. On the other hand, Cleveland (*d*) says that in 4 cases in children, in no single instance did lumbar puncture have any effect on the course of the disease, and even intracranial drainage had very little effect; whilst Babinski (*e*) seems to think that cranial puncture with free drainage gives better results, at any rate in the case of intracranial neoplasms with cerebral œdema.

In adults, where the prognosis is so bad, it seems to me that any procedure which may improve the condition of the patient—if only temporarily—is quite worth a trial; and if a single lumbar puncture—perhaps done for diagnostic purposes only—affords any relief, then I think it would be quite worth repeating, frequently if necessary, if only to give time for the trial of other remedies. And this brings me to the question of tuberculin.

Now, tuberculin is not an active rememdy, like, say, potassium iodide in syphilis, and needs as a rule a fair amount of time to develop its full action, which lies in stimulating the production of antibodies to neutralise the toxins, though we must remember also that Beraneck has proved that tuberculin has the power of weakening the virulence of tubercle bacilli.

If the meningitis be but a part of a generalised tuberculosis which may not have had full time to develop before the meningeal part has caused death, it follows that tuberculin can probably do very little good. But if the meningitis is not part of a generalised tuberculosis, and is, so to speak, only a secondary localised infection, then we may possibly be able to do some good by the employment of tuberculin, especially if we can prolong life by ameliorating the effects of the increased cerebro-spinal fluid by performing lumbar puncture. After all, the symptoms and signs which we associate with meningitis seem to be chiefly those due to pressure, though, of course, toxin poisoning must play a part, and, if frequent or continuous drainage will hold these in abeyance, there may be time to develop a certain amount of immunising power by the exhibition of tuberculin.

It has been stated that the increased intracranial pressure is not the immediate cause of death, but that this is probably due to the effects of an inflammatory process in the brain. If this is so, one would have expected it to leave some after effect in, or on, the brain of those children who recover, but so far as I can find most of them seem to have recovered perfectly—one reported by Dr. Martin certainly had slight right monoplegia of the arm. Perhaps in those who recover this inflammatory process is not very marked.

Coma and convulsions may also be due to absorption of toxins from the cerebro-spinal fluid; if so, drainage by lumbar puncture will of necessity reduce the amount available for absorption, and so should help towards improvement and give an opportunity for using tuberculin.

Again, in tuberculous meningitis it is quite common to find scanty tubercles in the fossa of Sylvius, and the initial number of bacilli is probably small and the general phenomena of intoxication are often quite slight, and it therefore seems possible that the development of the disease might be cut short by tuberculin, especially when one remembers that it weakens the virulence of the bacilli, and even to a large extent dissolves the bacillary substance (Sahli); and this action would also extend to the free bacilli in the cerebro-spinal which probably help to spread the disease.

Further, since the free bacilli and small tubercles are in direct contact with the fluid into which antibodies can easily pass, these bacteriolytic and antitoxic actions of tuberculin may be more marked in the case of the small tubercles of tuberculous meningitis than in the case of the large, more compact, foci of disease such as exist in the lungs, where the absence of blood-vessels prevents the development of the full action of the tuberculin.

Theoretically, if this is regarded as localised tuberculosis the method of "immunisation without tolerance" described by Riviere and Morland, should be used. In this method tuberculin is given in small constant (optimum) doses at fairly long intervals of, say, 14 days, so that the tolerance of each dose may disappear before the next is given. But, unfortunately, the usual duration of the disease is very short, and if we are to do any good it seems to me that we must get in more than one dose of tuberculin—which is practically all that time would allow by this method; and I would suggest starting with a very small dose of tuberculin (B.E. or P.T.O.), and then giving small but increasing doses every third or fourth day, as it is necessary to produce an active immunity as soon as possible. A child was treated on these lines, and the meningitis certainly retrogressed though death ultimately resulted from broncho-pneumonia.(*a*) In one of my cases tuberculin was tried, but not until the disease had been going on for over a fortnight, and then it made no difference.

Of course, one of the main difficulties in giving tuberculin in these cases lies in the focal reaction, which will increase the headache, but this might be controlled by morphia. In a case of cerebral tumour—the notes of which have been sent me by Dr. Trubshaw of Mold, and in which the diagnosis was confirmed by Dr. Hill-Abram—tuberculin was used in fairly large doses at intervals of about 14 days, and though it produced very severe headache and some vomiting at first, the girl recovered, and now, 2 years after, feels very well and has no symptoms. But, of course, this differs from meningitis in being a slowly progressing growth and therefore just the class of case in which tuberculin should do good.

But if the cases of meningitis be diagnosed with certainty early enough it would seem quite worth trying tuberculin—even though the reaction increased

the headache—combined with lumbar puncture to relieve pressure and drain off toxins, as otherwise the prognosis is almost absolutely hopeless.

I am indebted for information as to certain cases to the medical superintendents of the following sanatoria: Nordrach-on-Mendip, Linford, Cotswold, Mundesley, Crossley, Delamere, Benenden, and East Anglian.

OPERATING THEATRES.

BOLINGBROKE HOSPITAL.

IRREDUCIBLE FEMORAL HERNIA.—MR. SWAINSON operated on a woman, æt. 52, with an irreducible femoral hernia. There was a five years' history. Up till two weeks ago the patient had received no treatment. The swelling then became irreducible and gave rise to pain. On admission there was a swelling over left femoral ring about the size of a walnut, the principal diameter of which was clearly below Poupart's ligament. The swelling was to the outer side of the pubic spine and fluctuated. A diagnosis of femoral hernia was made and it was decided to operate.

A straight vertical incision was made over the swelling about three inches in length, and commencing about half an inch above Poupart's ligament. The incision was deepened at the upper end to expose the external oblique. The sac was readily separated by blunt dissection with two pairs of forceps, and on opening it with scissors it was found to contain about three drachms of serous fluid. The neck of the sac was then isolated and pulled down a little, clamped, ligatured and allowed to slip back into the abdomen. A mattress suture of iodised catgut was passed through the fascia over the pectineus and the inner end of Poupart's ligament drawing them together and to some extent occluding the femoral ring. No vessels required ligature, four small ones being closed by forcipressure and torsion. The wound was sewn up with silkworm gut.

Mr. Swainson said that this case might be called a hydrocele of a hernial sac. It was essentially a hernia, and the important thing to do was to remove the sac. The method of closing the femoral ring by a mattress suture was satisfactory as regards results. Alternatively, a flap of pectineus muscle and its fascia might be turned up and sutured to Poupart's ligament. Mr. Swainson said he had had no experience of the insertion of a metallic staple fixing the inner end of Poupart's ligament to the pubic bone and thus closing the femoral ring—the method associated with the name of Roux.

IRREDUCIBLE UMBILICAL HERNIA.—Mr. Swainson operated on a woman, æt. 53, who was the subject of a large irreducible umbilical hernia. The coverings over the swelling were much thinned, and it was possible to make out with tolerable accuracy the presence of bowel and omentum. The woman was obese, and in the large transverse fold of integument below the swelling there was some intertrigo; this had been diminished by treatment previously. The parts had been sponged over with a solution of lysol and then with a lotion of biniodide of mercury in methylated spirit.

The swelling, which was about the size of the top of a cottage loaf, was included between two curved incisions, which together formed an ellipse, the major axis of which was ten inches in length and transverse in direction, the minor axis being about five inches. The incisions were gradually deepened through the fat to expose the external oblique, and the neck of the sac gradually approached by careful dissection above and below and at the sides. Partly by tearing and partly by dissection with scissors the sac was isolated and a small opening made into it. The opening was gradually enlarged and adherent bowel and omentum drawn out, adhesions being ligatured from time to time. Large heavy clamp forceps facilitated this process. Before the adhesions could be properly freed it was necessary to draw out more than two feet of colon; there was no small bowel in the sac, and a considerable portion of omentum was removed. After tying all the small vessels and sewing up a hole in the meso-colon, it was possible to return all the bowel into the abdomen and to cut off the neck of the sac flush with the abdominal wall. The aperture into the abdomen, when stretched laterally, presented a transverse slit some four inches long, it having been increased by about one inch by a transverse cut with scissors. It was still further increased transversely for about one inch by another cut with scissors, and it was then found possible to overlap the edges of the incision, the upper edge being drawn under the lower edge. This was fixed by two mattress sutures of stout thread and an overlapping continuous stitch of iodised catgut. The upper and lower edges of the wound, comprising skin and much subcutaneous fat, were now brought together so as to leave, when sewn up, a straight transverse incision ten inches in length.

Mr. Swainson said that he recommended the operation he had performed as giving good results. The parts could, as a rule, be brought together without much tension. It was sometimes possible, by making transverse incisions outwards from the neck of the sac, to split the abdominal wall into layers and overlap them, thus giving additional security. Sometimes, as in this case, the muscular and aponeurotic portions of the abdominal wall were so thin and parchment-like that it was better to merely overlay, and not split them into layers.

TRANSACTIONS OF SOCIETIES.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD JULY 2ND, 1913.

The President, MR. J. M. COTTERILL, F.R.C.S., in the Chair.

DR. SYM and MR. SCOT SKIRVING showed a girl, æt. 24, after

EXCISION OF AN ORBITAL FIBRO-SARCOMA

by Kronlein's method. There was slight impairment of vision, which disappeared after hypermetropia had been corrected. There was proptosis in the axis of the orbit. There was no impairment of movement. It was thus seen that the tumour was not attached and that it lay within the cone of the muscles. The absence of a bruit or thrill favoured the view that the condition was neoplasm. The absence of neuritis indicated that the optic nerve was not involved. The tumour was removed by Kronlein's operation, but the incision was made concave forwards and there was very little scar. The result was otherwise very good except for impairment of the movements of the external rectus.

MR. SCOT SKIRVING showed a girl, æt. 9, treated by ileo-sigmoidostomy for inveterate tuberculosis of left humerus and scapula. There was improvement for about a month after the operation. Since that time the condition has remained *in statu quo*.

MR. G. D. MATHEWSON read a paper on

CONDUCTION DEFECTS IN THE HEART.

The importance of recognising conduction defects was considerable, as they not merely indicated that the auriculo-ventricular bundle was affected but gave evidence of much wider affection of the myocardium. In complete heart block the ventricle usually had a beat of about 30 per minute, while the pulsation of the jugular vein was often twice or three times as rapid. Many of these cases could be recognised without the electrocardiograph. In cases of partial heart block the electrocardiograms gave important help. Vagus stimulation might exaggerate the effect of partial heart block. The organic blocking was not removable by means of atropine. The digitalis group depressed conductivity and were contra-indicated in heart block. The most hopeful cases were the syphilitic where a gummatous change might be affecting the auriculo-ventricular bundle.

DR. RUSSELL said he was greatly impressed with the skill and ingenuity which had led to the introduction and use of this form of research. There was, however, a tendency on the part of those who carried out the work to exaggerate the significance, or rather the importance of the method. It supplemented but did not displace the older methods. The significance of heart block was that some of the branches of the A.-V. bundle were involved in a degenerative process, but there might be extensive degeneration without these bundles being involved.

Dr. W. T. RITCHIE remarked that it was only after the introduction of the string galvanometer that such conditions as auricular fibrillation and paroxysmal tachycardia has been elucidated. The method also gave information regarding the tone of the heart, and enabled the clinician to localise focal lesions.

A DISCUSSION ON INTESTINAL TOXÆMIA

was introduced by Dr. William Russell. A very wide field was included in the title. Two factors had to be recognised. These were the individual or personal factor and the substances dealt with (the extraneous factor). In connection with the personal factor, the great subtlety of the chemical dynamics of the animal body within normal or average limits had to be remembered and, besides, the most extraordinary idiosyncrasy to alimentary toxæmia from food, beverages and drugs might be met with. The substances to be dealt with came into such close relationship with the individual that the two factors could not be separated when the effects or results were looked at clinically. The broad problem before the clinician was based upon the fact of the prevalence of constipation or colon stasis. From the consideration of that problem might be excluded the person who ate in excess, and digested and assimilated what he ate, and became fat and plethoric.

The problems in conspitation were: (1) The effect of constipation on the secondary digestion, including in this the excretory side of the process and the consequent retention of the waste products of cell metabolism; (2) the absorption of bacterial toxins; and (3) the reflex effect of constipation on the vascular system. The absorption of bacterial toxins and their effects was an aspect of the problem which was a natural development of our modern knowledge of bacteriology, and in dealing with it the ordinarily ill-balanced tendency to consider this, the newest aspect of the subject, to the exclusion of others had been seen. The question of the absorption of products of intestinal putrefaction must be regarded from the standpoint of the accompanying constipation, which impeded and greatly hindered the detoxicating function of the liver. The passage of toxic substances into the blood was removed by the removal of the constipation. It was not claimed that we knew the number of these toxins; that we knew the effect on the body of any one of them save some of the most potent of the putrefactive products; and we knew less of the effects of combinations of them. The problem was further complicated by idiosyncrasy to common foodstuffs, and by probable variations in the susceptibility of the ductless glands to such substances. The abdomino-vascular reflex had an important influence in producing phenomena which are erroneously referred to toxæmia. Examples of the effect of the reflex were attacks of angina minor after a meal. The hypertension associated with a bilious attack could be dispelled by a dose of calomel or blue pill. Both as regards the influence of toxins absorbed and of constipation acting the individual susceptibility played an important part. The skill of the clinician lay in his power of giving to each factor its due and correct place in the individual case, realising that no single factor was the whole factor. Excessive protein food was the only demonstrable factor in an ocean of speculation. Attempts to rush the position as if the way had already been paved by science were utterly false.

Professor ALEXIS THOMSON said that the surgeon had great difficulty in connection with this subject because the physicians were not agreed about it, and it was obvious that in connection with several parts of it the surgeon had no *rôle* at all. He did not know where to draw the line between constipation and stasis nor between stasis and colitis. He had great difficulty in believing that stasis was to be accounted for mechanically possibly as a result of the erect posture. Nerve action played a large part, and he was not disposed to place too much reliance on X-rays, at least to the extent that they might indicate his course to the surgeon. Assuming that there occurred a condition of stasis in the colon that required operative measures for its relief, surgeons were not yet in a position to express an opinion, based on experience, as to the method of operation to be selected. The choice ranged from a simple appendicostomy, through various forms of short-circuiting or entero-anastomosis, to resection of a part, or of the whole large intestine. The choice would be mainly influenced by the comparative safety of the operation and by its efficacy in restoring the function of the bowel.

Appendicostomy was so safe and so efficient that it should always be considered before a more serious operation was performed. The results of ileo-sigmoidostomy were as follows. Patients required aperients for a fortnight after the operation. Three days after the operation a green stool was passed. The motions afterwards became more normal in colour and tended to be firmer but did not become formed. Their increased frequency was a drawback, but as a rule appetite increased and symptoms improved. If the physician could establish the existence of stasis and resulting symptoms, then the surgeon could give relief. The whole subject was in a state of transition, and it was impossible at this stage to come to any definite conclusion.

The PRESIDENT said he was in complete agreement with Mr. Thomson regarding appendicostomy. He had seen many cases where good results had followed. The major proceedings should be approached in a much more cautious spirit than some surgeons showed.

Dr. CHALMERS WATSON said that an important factor was the effect of constipation on the mucous membrane. Constipation alone could easily be put right, but if there were changes in the mucous membrane the patient might continue to void septic stools. Repeated examination of the stools might be necessary before an opinion could be formed. The natural stool and the irrigation fluid passed after an enema might be examined. If after ten weeks of drug and dietetic treatment with lavage there was no improvement then there was an indication for surgical interference. The results if intestinal toxæma might be seen as rheumatic or quasi-rheumatic affections, as neuræsthesia or as alimentary manifestations—symptoms simulating appendicitis or latent duodenal ulcer. In these cases he examined the stool and then placed the patient on a restricted diet. The effect on the stools was noted. It was not always possible to say how the treatment was effective, but it was often successful and symptoms disappeared.

Dr. PRICE said that in the course of the last three years he had examined some 150 colons with the X-rays. Physicians did not know how to treat cases of dilatation of the colon either early or late. The X-rays showed stasis and the amount of bowel that was affected by atony. The only operation the surgeon could perform was removal of the affected part. The colon was ballooned and thin and no use for absorption. If the surgeon knew the extent of this he could plant the ileum into a healthy part of the colon. The best operation was the one which saved the largest amount of healthy colon. The radiographer could show the surgeon what operation to do. The lesion was progressive and the surgeon alone could do any good.

Dr. GULLAND said that he thought the difficulties in some of these cases might be exaggerated. If it were ascertained that constipation was present and whether the constipation were due to an affection of the bowel or of some other part, most cases could then be dealt with successfully, though some were hopeless until the surgeon was called in. Much information regarding intestinal toxæmia might be got by an examination of the urine. Bacteriological examination of the fæces was not of much service, as most of the organisms present did little or no harm. Examination of the fæces was an important guide to the state of digestion and might give information regarding the condition of the intestinal wall.

Dr. FLEMING said that many persons showed no signs of intestinal toxæmia as long as they remained constipated, but suffered acutely as soon as they had an attack of diarrhœa. The passage of bismuth through the alimentary canal might be quite rapid, although there was a considerable amount of intestinal stasis.

BRITISH OTO-LARYNGOLOGICAL SOCIETY.

A clinical meeting of the Society will be held at the Medical Society's rooms, 11, Chandos Street, Cavendish Square, on Wednesday next, July 16th, at 5 p.m. Cases at 4.30 p.m.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, July 5th, 1913.

CYSTS OF THE WRIST.

THE treatment of cysts of the back of the wrist, so common in certain professions, is as simple as it is efficacious. The back of the hand is painted with tincture of iodine, and after five minutes the hand is bent so as to stretch the teguments and render prominent the little tumour. The cyst being fixed with two fingers of the left hand, a hypodermic needle is introduced and two or three drops of tincture of iodine are injected and the needle withdrawn. A gentle compressive bandage is applied for four or five days. If after that time the cyst is still apparent, a second injection is made, after which the cure is certain. It may happen, however, that a third injection is necessary, but it is very rare. The injection provokes no pain worth speaking of; a sensation of heat and numbless is all that is complained of.

The advantage of this method of treatment lies in the fact that the patient can continue his or her work as before. The injection of tincture of iodine has never caused any accident, says Dr. Pakowski, who has treated thus several cases.

Communication of the cyst with joint, affirmed by text-books, is in reality very rare, and even otherwise, the cyst being filled with a gelatinous mass, the iodine remains localised and cannot reach the articulation.

BRONCHO-PNEUMONIA OF INFANTS.

It must never be forgotten that infants are very sensitive to cold, and should be sufficiently protected against changes of temperature. Broncho-pneumonia is a very common consequence of more or less prolonged exposure to cold.

Once the malady has set in we have no means, says Dr. Pironneau, of arresting the process which has invaded the pulmonary tract. The child will in any case be placed in a large, ventilated room and isolated, if possible, as the malady is more or less contagious.

Against the congestive phenomena, revulsion by means of mustard is very useful. Eight doubles of thin gauze, impregnated with a warm liquid mixture of brown mustard, are applied as a jacket around the thorax and left on five or ten minutes, after which a warm bath of ten minutes is given. The application is renewed two or three times a day.

The temperature of the room should not be inferior to 84° F., while the apartment will be steamed by the vapour of eucalyptus leaves. An atmosphere saturated with watery vapour is very useful to facilitate the expulsion of the mucous secretions, while it diminishes the cough. Inhalations of oxygen gas render good service in cases of cyanosis; subcutaneous injections of the same gas are also very stimulating.

If the child is depressed, subcutaneous injections of camphorated oil or artificial serum are indicated. As general diffusible stimulants, a little brandy or champagne and water may be given.

Where there exists an element of infection, intramuscular injections of electrargol or frictions beneath the arms of collargol ointment are useful. During convalescence, the child will be protected against cold by flannels and will not be carried out of doors unless the temperature is soft and warm.

TYPHOID FEVER.

Dr. Vernier, of Hyeres, has a method of his own for treating typhoid fever, and if his reports are correct, which we have no reason to doubt, it is very successful.

As soon as the malady is diagnosed, he prescribes for the first day an intestinal disinfectant as follows:—

Calomel, 12 gr.
Salol, 6 gr.
Lactose, 1 dr.

Divide into three powders; one every six hours. (These powders are renewed every fourth or fifth day.) A large cup of milk is ordered every three hours, and during the intervals diuretic drinks and weak beef tea. As principal treatment he gives half-an-hour before each cup of milk half a wineglass of

Tincture of iodine, 80 drops.
Pearson's solution (arsenical), 50 drops.
Iodide of potassium, 2 gr.
Sulphate of strychnine, 1-5th gr.
Boiled water, 1 pint.

This solution is suspended the day calomel is taken.

A large place is given to disinfection of the natural orifices—mouth, nose and pharynx. The teeth are brushed morning and evening with a soft tooth-brush moistened and rubbed with soap. The mouth and throat are rinsed after each cup of milk with a solution of salicylate of soda, to which is added a little glycerine, and also once or twice a day with a little alcohol and water to tonify the mucous membrane. The following ointment is introduced into the narines night and morning:—

Boric acid, 30 gr.
Resorcin, 6 gr.
Menthol, 1 gr.
Vaseline, 6 dr.

During the whole course of the malady a cold enema is given night and morning.

With the iodo-arsenic method and hygienic precautions above mentioned, all his patients (30 cases) got well without having to resort to cold bathing. In some forms of hyperthermia the author applied cold compresses to the abdomen, and sometimes the ice-bag to the heart. In any case, with the therapeutic tripod—iodine, arsenic, strychnine—the temperature fell between the twelfth and the twentieth days.

GERMANY.

Berlin, July 5th, 1913.

AT the Congress für Gynæcology, Hr. Sellheim, Tübingen, discussed

THE RELATIONS OF THE REPRODUCTIVE FUNCTIONS OF WOMEN TO THE HEART.

He showed graphically that the loss of blood of a well-nourished woman during menstruation reached in amount double that of her body weight at eighteen years of age. Then came the period of building up, when the material was furnished for the development of the fœtus and its nourishment after birth. With six children the mother had again twice built up her own corporal structure. From his own physiological examinations he was satisfied that, contrary to what might have been expected, there was no sexual difference between the woman's heart and the man's, and no anatomical basis for such an assumption. On the contrary, compared with the male curve the female heart between the twentieth and the fortieth year showed a falling off. The temporary high requirements of the female heart, corresponding to the efforts of reproduction. showed a retardation as regarded increase of bulk at a time when. from a physiological point of view, an increase might have been expected.

Hr. Krömer discussed

THE DISTURBANCE OF THE RENAL FUNCTION IN ECLAMPSIA.

Excluding, he said, the rare cases in which there was no albumen in the urine, in eclamptic cases, in addition to excess of albumen and cylinders there was oliguria with a high specific gravity, and especially retention of sodium chloride, which never failed in the anasarca cases. Sudden drop of the chloride curve was an indication of threatening eclampsia; it also indicated a return of the fits in the puerperium. The atypical albumen-free urine cases with normal excretion of chlorides were exceptions, they afforded no prognosis and were the most suitable cases for the Stroganoff treatment. The test of the eclamptic kidney by means of pheno-sulpho-phthalein confirmed the serious mischief in the kidneys, as the colouring material was excreted only up to 40 or 50 per cent., and in the first two hours only to 25 per cent. where the kidney was injured, whilst when the kidney was sound, excretion took place up to 60 to 75 per cent.

Hr. Vogt, Dresden, spoke on

PREGNANCY AND ADDISON'S DISEASE.

He said that only one case had been recorded—by Barlow. The cause of the disease was syphilis of the suprarenal capsule. A second case had been observed in the Dresden Klinik years ago; here there was tuberculosis of both bodies. The pregnancies ran a normal course in both instances, also the labours. Patients suffering from morbus Addisonii were in far greater danger in the early part of the puerperium than during pregnancy, or even through the labour itself.

Hr. Novak related the results of experiments on rats made with a view of learning the relation, if any, that existed between the suprarenal bodies and the genital organs. His view was to determine what followed extirpation of the suprarenal bodies as regarded the genital functions. His experiments were made on 146 rats. As these animals had an accessory suprarenal structure, there was by no means total exclusion of the influence of these bodies but only a hypo-function which, in most cases, led to a fatal issue in a shorter or longer time. The rats that had been deprived of their suprarenal bodies showed a distinctly faulty sexual development. This anomaly was the more pronounced the younger the rat was. Both impaired potency and capability to conceive were very pronounced. In two rats that were deprived of the bodies in question during pregnancy this did not undergo any interruption.

Hr. Ad. Schmidt, as a guest, discussed

DISEASES OF THE HEART AND PREGNANCY.

He said that even to-day, auscultation and valvular disease held a higher place in the treatment of cardiac cases than they ought to do. The intensity of the murmur and the accentuation of the impulse did not run parallel with the gravity of the cardiac disease. That was the case in mitral stenosis, although he otherwise recognised its special position. Much more important were the size of the heart, the changes in the pulse, the persisting stasis in the liver, and the lesser circulation, and, above all, the capacity for function in the heart and its reserve of power. It was not every decompensation that had such a grave significance as regarded prognosis. It depended rather on what was the cause of it, what form it showed, and how it reacted to digitalis and rest. If it should be said here that myocarditis in pregnancy demanded interruption of the pregnancy, it would be true of the severe cases only. There were a number of milder cases only characterised by acceleration of the pulse, after bodily exertion, in which there was no indication for this. Between this and the worst forms were all possible degrees. I must be accepted that the milder forms of myocarditis, after anginas and other infections, were of bacterio-toxic origin. There was the question whether cardiac diseases in pregnancy were not more affected by the toxins than by the mechanical factors. It should not be looked on as something that was certain that a myositis in pregnancy, a decompensation in the first half of it a combination of heart disease with nephritis, always called for artificial termination of the pregnancy. Nothing remained but to judge and decide each case for itself.

DR. E. PARRY EDWARDS has been appointed County Medical Officer and School Medical Officer for Carnarvon.

AUSTRIA.

Vienna, July 5th. 1913.

AUTO CÆSAREAN SECTION—WITH RECOVERY!

AT the meeting of the K.K. Gesellschaft der Aerzte which was held in Vienna on June 6th, Dr. R. Patek showed a woman who, four years previously, had, at the conclusion of the full period of pregnancy, cut through the anterior abdominal and uterine walls with a razor—by a single slashing incision! The fœtus was extracted alive; and, as the medico-legal investigation of the case showed, was drowned in the suds contained in a washing-tub into which it had fallen. The woman was brought into hospital, where the edges of the uterine wound were carefully approximated and sutured after complete disinfection. The peritoneal cavity was duly drained, and the opening in the abdominal wall closed by careful approximation of its various layers. The patient soon recovered. And now the supplementary report was forthcoming: she had again become pregnant, after an interval of four years from her former experience; and, on this latter occasion the process of parturition had been normally completed, notwithstanding the fact that an abdominal hernia had formed at the seat of the former self-inflicted incision.

RADIUM-RAYS IN THE TREATMENT OF UTERINE CARCINOMATA.

Dr. E. Wertheim made a communication which described the treatment of two cases of uterine carcinoma with radium-rays. In both cases the alpha and beta-rays were screened by enclosure in a leaden capsule of 2.5 mm. thickness, so as to prevent any deleterious action of the surrounding tissues. This was placed in the vagina, immediately before the portio vaginalis uteri. In one of the cases, which up to the date of the report had been treated to 2,500 mg. periods, the growth had proved completely refractory. The case was one of a hard, fissured growth on the surface of the portio vaginalis, which presented the microscopic characteristics of adeno-carcinoma. In the second case, on the other hand, the influence of the radiations was extraordinarily striking. Before the beginning of the treatment, a soft cauliflower excrescence, of the size of a hen's egg, completely filled the upper third of the vaginal canal, the uterine wall could not be distinguished, and the parametrium on the right side was infiltrated and puckered. Even as early as after the third night a marked deliquescence of the growth was observable, and at the close of the seventh night from the commencement of the treatment the cauliflower growth had completely shrivelled up. Examination now displayed only a shallow ulcer on the anterior lip of the os, which was quite soft to the touch; the posterior lip appeared wholly intact. The infiltration and puckering of the right parametrium had disappeared, and the case, which, before the commencement of the radium-ray treatment, had seemed placed beyond the border-limit of operability, since appears to have become a very eligible one for surgical manipulation, so that a radical procedure may now be adopted without any technical difficulty. The microscopic revelations in this case also demonstrated the effective action of radium. At the various successive stages of the treatment the examination of sections removed from the growth displayed changes precisely identical with those described by Döderlein and Bumm as taking place in the course of their mesothorium treatment. As the procedure is continued there occurs vacuolisation of the carcinoma cells, fragmentation of the nuclei, pycnosis; and, as the treatment still goes on, we have actual solution of the cell masses which had passed into the necrotic state. Thus the fact is established beyond doubt that, in cases of uterine carcinoma, we obtain by the radium treatment results completely similar to those obtained by the use of mesothorium. It is, indeed, very remarkable, too, that in the case just described, this effect was obtained in a relatively very short time—even after 1,500 mg. periods; while the authorities who have recorded corresponding results from the use of mesothorium were obliged to employ it up to 3,000, or

4,000, or 5,000—and sometimes even a greater number—of milligram periods.

But, for a complete cure, that consummation still seems as rare as was noted in the Halle report. The uterus was thoroughly examined after extirpation by Professor Schottländer, and he found numerous cancer cell groups, not only in the cervical canal, above the os uteri, but also on the posterior wall; and, indeed, some of them were placed at specially remote distances from the original surface growth. Whether these deposits could also have been brought to shrivel and disappear under the radium treatment is a question which must, of course, remain open for the present.

CANADA.

Toronto, June 24th, 1913.

Meeting of the Ontario Health Officers' Association.

On May 29th and 30th, the annual meeting of the Ontario Health Officers' Association took place in the Parliament Buildings, Toronto. The meeting was largely attended, and some really excellent papers were read. Among these were papers by Dr. Charles H. Hastings, Medical Officer of Health of Toronto, and Dr. Dickinson, dealing with the "Duties of the Modern Medical Officer of Health in Cities and Towns," while a feature of the meeting was the reading of a paper by Professor Whipple, of Harvard, entitled "The Value of Vital Statistics in Relation to Public Health."

The paper read by Dr. Charles Hodgetts, Medical Adviser to the Canadian Commission of Conservation, Ottawa, aroused a considerable amount of discussion. He argued that medical inspection of schools, being a part of public health work, should be placed under the direction of the health department and not in the hands of the board of education as is the case in Toronto. He contended that the existing system caused duplication of work and a waste of public money. Also he objected to nurses being allowed to make diagnoses of disease in school children. The members of the association present evidently were of the same opinion as Dr. Hodgetts, as a resolution was passed to be sent to the Minister of Education requesting that the medical inspection of schools be transferred to the control of the Ontario Provincial Board of Health.

Dr. J. A. Amyot, in the evening of May 29th, gave a public address on "The Transmission of Communicable Disease." On the second day a lively discussion was initiated by the proposal that the medical practitioner should be paid for reporting communicable diseases, births and deaths. The general opinion appeared to be that the practitioner was entitled to remuneration for work of this description, and a resolution was passed to the effect that the local municipalities be required to pay a fee of fifty cents (2s.) for reporting each birth and death and each case of communicable disease.

Dr. Parfitt and Miss Eunice Dyke read papers on subjects relating to tuberculosis, while the milk question was discussed in papers read by Drs. G. G. Nasmith and A. W. Macpherson. Two papers were read on the sewage question—one on "Disposal of Waste and Garbage," by Dr. Hall, and the other paper on "Disposal of Domestic Sewage," by Dr. R. E. Wodehouse. Sanitary work amongst foreign population was dealt with Dr. C. N. Laurie.

Dr. Chas. J. Hastings, Medical Officer of Health of Toronto, was elected President of the Association for the coming year.

CONTINENTAL HEALTH RESORTS.

Aix-les-Bains.

Aix-les-Bains is at present crowded with visitors of every nationality. This is not surprising when we consider its accessibility, the attractiveness of its surroundings, and its central position for pleasure excursions on land and lake; mountains, glades, ravines and caverns on every side contribute to the beauty of this queen of French summer resorts. Its amusements, too, are equally abundant and diversified. In its casinos and theatres, operas, concerts and "distractions" for young and old are lavishly provided from noontide to midnight. Golf links, tennis courts, hippodromes, pigeon shooting, horse races, and even dog shows are not wanting. All tastes are amply catered for, so that each individual guest may select for himself out of the abundance offered. Each also can choose from a wide range of excellent hotels, pensions, apartments, villas, chalets and cottages the most suitable accommodation.

There is certainly no lack of choice, whether of residence or amusement, at Aix-les-Bains. The musical performances here are, as they have long been, of genuine artistic interest, and the theatrical presentations and ballets are unexcelled. The "Grande Cercle" Casino has a hall renowned for its mosaic ceiling and coloured glass, a commodious theatre with fine scenic appliances, handsome salons for balls, concerts, baccarat and other games of chance, reading and writing rooms comfortably arranged and liberally supplied with magazines and journals in various languages; dining rooms and café-restaurants overlooking beautiful lawns on which fêtes are held daily and nightly. The "Villa des Fleurs," in extensive grounds, has also splendid salons for concerts and games and an open-air theatre, which is very agreeable during the fine summer evenings with which Aix is greatly favoured. Amongst the beautiful excursions that can be made from Aix is that to the picturesque Lake Bourget, with its old Chateaux de Bourdon and Chatillon and its ancient Abbaye d'Hautecombe (the Westminster Abbey of Savoy), containing the remains of princes of the Savoyard Royal House, under monuments of vastly different styles ranging from strictly classic severity to almost grotesquely flamboyant. Amongst those quietly resting here are some connected with our Plantagenet dynasty.

There are many exquisite trips by rail or carriage to the Gorges du Sierros and the Grèsy Cascades, also the famous Gorges du Fier, where, on terraces overhanging the ravine torrent, the visitor may lunch on delicious trout caught and cooked while waiting. A mountain railroad ascends from Aix to the semi-Alpine "After Cure" at Corbières, at an altitude of about 2,000 feet. The cog railway goes farther up the cliff side to Mont Revard, a resort 5,000 feet above sea level, where are hotels and chalets commanding superb views over parts of the Mont Blanc, Dauphiny and Chartreuse Alps. On Mont Revard is the recently developed Source des "Deux Reines" taking its name from Their Majesties of Holland, who were much gratified by their residence in the Corbières Sanatorium. The water of this spring, slightly mineralised and of great purity, is greatly appreciated as an internal adjunct to the external "Aix cure." The frequent passing in the streets of Sedan chairs (an admirable peculiarity of Aix-les-Bains for carrying patients safely to and from the baths and douches) reminds one that underlying and overlapping all else, and far more essential than exquisite outdoor scenery or indoor artistic attractions, the prosperity of Aix is primarily and permanently based upon the excellence of its medicinal springs; the modern appliances for the use of these waters (the arrangement of the thermes giving the physicians facilities for daily variations of heat and pressure so as to exactly meet each invalid's needs), the world-wide renowned "Aix massage" given here with inherited skill, and the high status of the Aix medical practitioners, whose thorough knowledge of how best to adapt the cure to each special case enables them to most efficiently utilise the remedial waters, the scientific appliances, and the skilful manipulations placed here under their control. Those wishing to best enjoy the place should come here in May or early in June, or after the middle of August; the hotels are less crowded, the weather delightful, and the hills, valleys and glades charming in their beautiful autumnal colourings.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Treatment of Tuberculosis in Edinburgh.

At the meeting of the Edinburgh Town Council on July 1st, notice was given of a motion to remit to the Public Health Committee to consider the expediency of the Royal Victoria Hospital, the Dispensary, and the Farm Colony being transferred to the Corporation, and to confer with the directors accordingly. At the same meeting a letter was read from Sir Robert Philip, intimating his acceptance of the post of expert adviser in connection with tuberculosis. The motion foreshadows a satisfactory solution of the difficulties which seemed to be growing up around the treatment of tuberculosis by the Corporation and the Insurance Committee. In the first place, it follows the lines of the Astor Report in making full use of existing agencies, and puts aside all idea of erecting independent competing institutions in a city already well supplied. Then it does away with one of the objectionable features of the original scheme—the treatment of early, curable cases and the segregation of advanced cases in the same hospital. If the principle of the full utilisation of the various parts of Sir Robert Philip's machinery be adopted, there is no doubt that the details of their transfer to the town will easily be adjusted, and in these circumstances Edinburgh will be in a very advantageous position in regard to tackling the tuberculosis problem.

National Insurance Act.

The first report of the Scottish Commissioners on the working of the Act has just been issued. It is stated that the initial working has been attended with less difficulty than was anticipated, and that the chief resistance was offered by farmers in certain well-defined areas and by employers of domestic servants, but that in the latter case the amount of persistent refusal to pay contributions has been small. Another class that has been prominent in opposing the Act is that of the Scottish shore fishermen, the question with them, however, arising out of the peculiarities of their employment, and being one of interpretation rather than evasion of the Act. The total number of insured persons is 1,434,966, a net deficit of only 39,000, as compared with the actuarial estimate. One of the chief problems awaiting solution is that of the casual labourer, especially in connection with agricultural work, and a special study of this is to be made by the inspectors during the ensuing summer. The number of deposit contributors is only 37,000—about half the actuarial estimate and not more than 2½ per cent. of all insured persons. The voluntary contributor has turned out an almost negligible element in the scheme. A list of the practitioners on the various Scottish panels is given, with the average number of insured persons per doctor in each area. In the counties, Orkney stands lowest with 137 patients per doctor, and Linlithgow highest with 737. The most common figures are between 300 and 400. In burghs, Rutherglen is lowest with 255, and Dundee highest with 1,638. In Glasgow and the Clyde district generally the number is about 1,000; in Aberdeen and Edinburgh 875 and 850 respectively. In the smaller burghs those with the largest number of patients appear to be those in which there is much female labour. For instance, in Leith the average is only 539, whereas in Kirkcaldy it is 967. Another factor which conduces to variation in these averages is the proximity of one burgh to another. In Leith, for instance, in which a very large proportion of the population is insured, the number of doctors on the panel is raised by the inclusion of many Edinburgh doctors, whereas in a town like Kirkcaldy, which stands isolated, the number of practitioners on the panel is not raised from outside. The number of persons permitted to make their own medical arrangements was at March 31st 6,555, or 0.44 per cent. of the total insured. Under heading of chemists this paragraph occurs:—"It is understood that in England, as contrasted with Scotland, the amount of medicine consumed per patient is higher; that the period for which medicines are prescribed to last is shorter, leading to more frequent repeats and consequent dispensary fees; and that the proportion of mixtures which are quickly made up to such preparations as pills and powders, which take some time, is considerably greater. Thus the Act has directed into the hands of the English chemist an increased volume of trade without conferring on Scottish chemists an equal or corresponding advantage."

Honorary Graduates at Edinburgh.

At the summer arts graduation ceremonial in the McEwan Hall, on July 4th, the hon. degree of LL.D. was conferred on, among others, Professor Greenfield, Dr. W. Allan Jamieson, Dr. John Stewart (Nova Scotia), Geheimrat Professor Strassmann (Berlin), and Professor J. Arthur Thomson (Aberdeen). Professor Greenfield is the late occupant of the Chair of Pathology in the University, which he held from 1881 to 1912; before that he was at St. Thomas's Hospital and the Brown Institute. Dr. Allan Jamieson is the well-known dermatologist, appointed in 1899 as the first University lecturer on diseases of the skin. Dr. Stewart was a house surgeon of the late Lord Lister in 1878, and has attained a high position in Canadian medicine. Dr. Strassmann is an eminent medical jurist, a successor of Caspar and Liman, whose pupils have almost a monopoly of the teaching of forensic medicine in German universities. Professor Thomson is the well-known biologist, fertile with his pen, and an adept at utilising the generalisations of biology in the service of sociological progress.

Report of Edinburgh Medical Officer of Health.

In his annual report Dr. Williamson deals exhaustively with housing conditions in relation to mortality, and points with satisfaction to the fall from 27 per mille forty years ago to 14 per mille at the present time. On analysing the returns it is found that the death-rate with the rarest exceptions follows density of population, and therefore a continued reduction depends on improved housing—prevention of undue massing of the population on restricted areas, supervision as to the subdivision of dwelling houses, and the closing of condemned houses. Cancer is showing no signs of diminution; it claims as many victims in the city as phthisis. The question of notification is hinted at and that of special hospital accommodation urged. The infantile death-rate has fallen to 110; only a few years ago it was 140-150. Here especially the housing conditions tell. In a suburban ward it is only 46, in St. Giles ward 155 per 1,000, while in certain areas it is as high as 250 and 277 per 1,000. Dr. Williamson advocates the utilisation of Colinton Farm Hospital for the treatment of early as well as late cases of phthisis; it has accommodation for 716 patients, and has never been occupied by more than 467. In 1907 651 cases of phthisis were notified; in 1912 there were 1,255—a figure indicating greater care, not an actual increase. The amount of phthisis varies directly with density of population—1.3 per 1,000 in the suburbs, 3.1, 4.5, 7.1 in the poor districts of the town. The birth-rate continues to decline. Comparing 1903 and 1912 we get the following figures:—

	Population.	Deaths.	Rate per 1.000.	Births.	Rate per 1.000.
1903 ...	318,219	4,963	15.59	8,112	25.49
1912 ...	321,884	4,701	14.6	6,700	20.81

BELFAST.

Lindsay Golf Cup.

In connection with the Ulster Medical Society the gold cup presented some years ago by Professor Lindsay was played for at the links of the Larne Golf Club, by the kind permission of the Council, on Wednesday, June 25th. There was a good entry, and Mr. T. P. Crymble, with a handicap of 5, was the successful competitor, Mr. A. B. Mitchell, with a handicap of 18, being the runner up. The competitors were most hospitably entertained to lunch and tea by Dr. and Miss Rankin.

British Medical Association.

At a meeting of the Belfast Division, held on June

24th, Dr. A. P. B. Moore was elected Chairman, and Dr. W. L. Storey was elected Secretary. Dr. Storey was also elected representative to the coming meeting at Brighton.

Royal Victoria Hospital.

The McQuitty Memorial Scholarship founded by a number of friends and patients of the late Dr. W. B. McQuitty was awarded, after examination, to Mr. W. McK. H. McCullagh. This is the second award since the scholarship was founded.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

MEDICAL RESEARCH.

To the Editor of The Medical Press and Circular.

Sir,—Regarding my letter to the *Times* of June 25th, I think that you have read into it somewhat more than I actually expressed. My point is that it would have been better to have included the names of all distinguished workers on medical research in the committees of the great national fund for medical research. This applies especially to the Advisory Committee, which is not paid, and the counsels of which could therefore have been easily assisted in this manner without expense. It has been a little tactical error to omit some of the persons of whom I was thinking, more especially because such omission is habitually practised in this country. I could mention instances in which those who have actually done important work in several lines have never been consulted in the further prosecution of study on those lines, when such further prosecution has been undertaken by British Governments (generally after much palaver). England is a country in which the "climber" is very much in evidence; and the defect referred to is one which can be remedied only by giving prominent public notice to it.

At the same time, I think that in other respects the proposed scheme is excellent. I was asked to give evidence before the Astor Committee regarding the organisation side (and I am not competent to speak on the scientific side of tuberculosis work); and I am glad that most of the suggestions made by me (and others) have been adopted. Those who have brought the scheme to maturity are deserving of the very highest credit. The departure is a new one and we must all support it to the best of our ability. This country has fallen quite behind the rest of the world in its attitude towards science and art; and I hope that this new departure is only the first of others which will be taken.

One more point: the prize offered for successful work does not appear to me to be nearly sufficient. The fact is that young men are refusing to touch medical science for the simple reason that they get nothing out of it. It is a British delusion to imagine that everyone is going to sacrifice himself for the good of the community merely for the honour of the thing. People enter the medical profession to make a living as much as for humanitarian purposes.

I am, Sir, yours truly,
Ronald Ross.

18 Cavendish Square, W.

THE ROLE OF ALCOHOL IN DIABETES.

To the Editor of The Medical Press and Circular.

Sir,—I have only just now finished the reading of Prof. Saundby's clinical lecture which appeared in your issue of June 25th; but if not too late, I should like to be allowed to thank him for his most lucid and convincing exposition of the *rôle* of alcohol in diabetes and in pseudo-diabetes, or glycosuria. If there is one fact in clinical experience the solidity of which seems to me unshakable it is the fact that in any and every disease in which depression is a recognisable symptom alcohol, as a therapeutic agent, is invariably pernicious to the last degree. Whether or not aware of the true character of their malady, the vast majority of patients suffering from diabetes or glycosuria are affected by the subjective symptom which I style depression, and a very considerable proportion have recourse to alcohol in search of relief. Alcohol invariably aggravates the symptoms, and when eliminated improvement always follows. My main object in writing is, however, to suggest how great must be the harm that is now being caused in these directions by the enormous traffic in sham tonics containing alcohol as their sole potent ingredient—a topic discussed in your editorial columns within the past few weeks. It is literally true to state that the use of these remedies is aways leading many thousands of simple people along the road to lingering and painful death. I never fail to inquire for this abuse in cases in which my suspicion is aroused, and I have been astonished at the number that have revealed themselves. It would be interesting to learn Professor Saundby's experiences in this connection. The sale of alcoholic secret remedies ought to be prohibited by law. This was the view taken by the *Times* a few years ago, when in a remarkable leading article it dealt with the question. It has been a puzzle to me why the temperance societies and their organs in the Press have not tried to force the matter before the attention of Government. The evils were graphically laid bare last year before the Select Committee on Patent Medicine by Dr. Mary Sturge, of this city.

I am, Sir, yours truly,
Temperance Reformer.

Birmingham.
July 4th, 1913.

NON-DIABETIC GLYCOSURIA.

To the Editor of The Medical Press and Circular.

Sir,—Nothing more timely than Professor Saundby's article on diabetes has appeared in the Medical Press and Circular for some time.

The fact is we torture patients weak enough to follow our advice by depriving them of various articles of food which are possibly harmless, and we render their existence a misery by suggesting that they have a dreadful disease, when in truth the trouble is often only a transient error in metabolism.

It is lucky for the ordinary citizen that scatology is a somewhat repulsive science, otherwise we should be eternally requesting patients to bring us a sample of fæces, and after test-tubing it and finding an imperfectly oxidised product of intestinal excretion, we should horrify them by informing them that they suffered from scatorrhœa, kakorrhœa, or some such awesome ailment. Doubtless substances as important as sugar or albumen pass unobserved through the bowel.

Dr. Saundby tells us to beware of considering every patient in whose urine we discover sugar as a diabetic. This is the beginning of wisdom. But let me propound a heresy.

Is there any proof that a very moderate amount of sugar, or a very moderate amount of ordinary bread—such an amount as the patient craves for—really hastens the death of a diabetic? Of course, I shall be told that careful dieting lessens the amount of sugar in the urine, and that the quantity of sugar is a measure of the severity of the disease. But is it?

It is not so long ago since we forbade the fever patient to drink cold water. Now we know that it is the only thing that does him any good. May not the thirst of a diabetic be equally curative? Can the unquenchable desire of such a one for saccharine foods be a self-destructive one?

Long ago Herbert Spencer taught us that all life-giving desires were pleasure-giving desires; but all medical practice seems obsessed with the fallacy that what a patient wants to do or to take is bad for him. The countless millions of the lower animal kingdom have instinct alone to guide them, and why should we regard it as unworthy to be listened to in the case of man.

Touching on treatment, hormone therapy seems to show promise of great things, but one is always waylaid by the *post hoc ergo propter hoc* fallacy. I have two or three cases at present under my care to whom I have given holadin—a preparation of the internal secretions of the pancreas. One is a woman of 55, another a man of 65, the third a man of 30.

They all look well and state they now feel in perfect health; the great thirst has disappeared, urine is scarcely above the normal in amount, appetite is not abnormal, and, in fact, they insist that they are quite well, and refuse any but the simplest restrictions in dietary. At the same time, the sugar, although lessened, is still quite easily found in the urine.

I am, Sir, yours truly,
J. C. McWalter.

July 3rd, 1913.

ST. BARTHOLOMEW'S HOSPITAL—A WARNING.

To the Editor of The Medical Press and Circular

Sir,—May I ask your aid in bringing to the notice of the public the fact that certain persons who represent themselves as agents of the Helping Hand Legal Assistance Syndicate (late Red Cross) are obtaining money by an improper use of the name of this Hospital.

These persons are in the habit of calling at houses, particularly in the poorer districts, and presenting a circular issued by the above-named Society to the effect that the Syndicate are subscribers to St. Bartholomew's Hospital. They then sell tickets at 3d. each, which they state will entitle the holder to treatment at this hospital.

This statement is quite untrue, and it is not a fact that the Helping Hand Legal Assistance Syndicate are, or ever have been, subscribers to this Hospital. I have in my possession a letter from the Secretary undertaking to withdraw the circular above referred to; but, as I find it is still in use, I desire to make it quite clear that the persons who represent themselves as the agents of the Syndicate have no connection of any kind with this Hospital.

I am, Sir, yours truly,
Thomas Hayes,
Clerk to the Governors.

July 7th, 1913.

"MEDICAL ADVISERS" IN IRELAND.

To the Editor of The Medical Press and Circular.

Sir,—I have resigned (June 21st) my recently accepted appointment as "Medical Adviser in Respect of Insured Persons who shall be Alleged to be Suffering from Tuberculosis," and in due course I published my resignation in the Dublin Press.

I am, Sir, yours truly,
Henry M. Harrison.

59 Rathmines Road, Dublin.
July 2nd, 1913.

OBITUARY.

MR. ALFRED WILLETT.

We regret to record the death of Mr. Alfred Willett, F.R.C.S., Consulting Surgeon to St. Bartholomew's Hospital, which took place at his country residence, Wyndham Croft, Turner's Hill, Sussex, on June 30th, aged 76. The deceased, who was born at Brighton in 1837, was the second son of Mr. W. Willett, and his mother a daughter of the late Mr. William Verrall, of Lewes. He was educated professionally at St. Bartholomew's Hospital, becoming M.R.C.S. Eng. in 1859. He was admitted F.R.C.S. in 1862. During the last twenty years of his career he took a considerable part in the administration of its affairs. He was twice a member of Council, and vice-President. In 1897 he delivered the Bradshaw lecture at the College. Other institutions with which he was connected were Queen Charlotte's Hospital, St. Luke's Hospital for Lunatics, the Foundling Hospital, and the Evelina Hospital for Children. He was a member of the board of management of the Metropolitan Convalescent Institution, and one of the court of directors of the Royal Sea-Bathing Hospital at Margate. Further work done by him was as examiner in surgery to the University of Cambridge and the Royal College of Physicians of London. King Edward's Hospital Fund for London was another body indebted to him for much excellent work. He was a member both of its general council and also of its distribution committee, and in connection with the latter he acted as a hospital visitor. He was a member of the British Medical Association, and was vice-President of the Section of Surgery at the annual meeting in London in 1895. As an operating surgeon he was conscientious and painstaking in the highest degree, and he was to a great extent a pioneer in the matter of the treatment of deformities by operative measures. Mr. Willett married, in 1867, Rose, daughter of Sir George Burrows, Bt., F.R.S., physician in ordinary to Queen Victoria, and leaves five sons and two daughters to mourn his loss.

REVIEWS OF BOOKS.

DISEASES OF THE SKIN. (*a*)

In writing a new work on any speciality designed for students there are two pitfalls to be guarded against—overloading with detail, especially debatable theories, and incompleteness, particularly with regard to treatment. To a certain extent a text-book of this nature must lay down the law; in other words, it should guide the learner along the intricate paths of diagnosis and show him the way with no uncertain lead. We have pleasure in stating that, after a careful perusal of Dr. Walsh's handbook, we can confidently recommend it to those desirous of obtaining a working knowledge of the principles of practical dermatology in the shortest time. "There is no royal road" to this speciality, as the author aptly remarks in his preface, for it is only by careful clinical observation and comparison that the student can become proficient in diseases of the skin. With Dr. Walsh's classification, which is one based on practical convenience, we can take no exception, except to the inclusion of lupus erythematosus among the new growths, for ulerythema is more generally regarded as being allied to the toxic erythemata. The modern view is adopted of eczema—the touchstone of a dermatological text-book—that it is essentially a symptomatic response to some irritant, whether acting from within or from without. Here, and also in the chapters on psoriasis and rosacea, we find expression given to the author's well-known observations upon the connection between chronic and recurrent dermatoses and certain forms of cardiac disease.

The treatment of each disorder is succinctly described, and numerous valuable formulæ are given for lotions and ointments. The use of the newer physical and chemical agents, such as Bier's hyperæmic method, X-rays, radium, carbonic acid snow, etc., is given in the appropriate place, though we do not find mention of ionisation, which has given good results in many skin affections. This and a few minor omissions will doubtless be remedied in the next edition. A good account is given of the Wassermann test and the use of salvarsan in syphilis. The number of misprints is remarkably few, the most important being "metin" for "luetin" on pp. 269, 270, and "irrigation" for "irritation" on p. 102. We have nothing but praise for the excellent photographic illustrations, which are "telling" in every instance. Finally, the publishers are to be congratulated upon the handiness and clearness of type of a volume for which we predict a great future.

ST. BARTHOLOMEW'S REPORTS. (*b*)

This interesting volume of the St. Bartholomew's Hospital Reports opens with an appreciative memorial article on the late Sir Henry T. Butlin, whose death we all deplore. Butlin had been connected with St.

(*a*) "Diseases of the Skin: A Handbook for Students and Practitioners." By David Walsh, M.D.Edin., Senior Physician, Western Skin Hospital: President of the New London Dermatological Society. Pp. xiv. and 298, with 29 illustrations. London: Bailliere, Tindall and Cox. 1913. Price 6s. net.

(*b*) "Saint Bartholomew's Hospital Reports." Edited by H. Morley Fletcher, M.D., and W. McAdam Eccles, M.S., F.R.C.S. Vol. XLVIII. 8vo. pp. xxix, 234 and 187. London: Smith, Elder and Co. 1913.

Bartholomew's since 1871, when he was appointed one of the Surgical Registrars, after which he successively filled the offices of Assistant Surgeon, Staff Surgeon, and lastly, since 1902, Honorary Consulting Surgeon. Well may St. Bartholomew's mourn the loss of her great son. Dr. F. W. Andrews is responsible for an interesting paper on the age incidence of intracerebral hæmorrhage, in which he shows that this condition begins to assume serious proportions at an age a little below 50 years. The apparent maximum incidence is at the middle of the sixth decade of life, but if due correction is made for the age distribution of a population the liability of the individual to this form of death increases steadily up to old age. We wonder is it to be looked on as a sign of the times that only one-third of the papers in this volume deal with medicine, the other two-thirds of the papers being surgical. The surgical papers, however, are of great interest, not only to the surgeon but to the physician, especially that by Mr. Vick on 100 cases of appendicitis, and that by Mr. Kerr on lateral sinus thrombosis. The latter part of the volume contains the usual statistical information of the hospital work. We must again deplore the paucity of the information supplied from the department of anæsthetics, only one page being given to the analysis of the 9,565 administrations. No death is recorded from this department during the year, a really remarkable achievement.

CLINICAL MEDICINE. (a)

THIS volume is an epitome of ways and means of detecting disease by clinical and laboratory methods of investigation. It is, in fact, an exposition of what we may call the *natural* way of approaching the subject, bearing in mind the time-honoured maxim that medicine is essentially a science of observation.

A patient comes to us complaining of *symptoms*, and it is for us to ascertain their significance and to find out what is behind them. The ultimate diagnosis is arrived at as a matter of course, but the first and immediate object is to procure trustworthy data.

Why the author should dedicate his work to " junior practitioners," is not too obvious, because, as a matter of fact, it is the senior practitioner who stands to gain most by refreshing his methods of investigation. So much of the valuable information herein contained must be vaguely new to men qualified more than ten or fifteen years ago, that without its help the latter must " wallow in ignorance " of the progress of diagnostic science.

One thing cannot but strike us, viz., the immense service rendered by X-ray observation in many diseases of internal organs—heart, lungs and pleura, and stomach, etc. We might, however, take exception to some of the results in regard to the stomach, because there is every reason to believe that gastric ptosis and deformation are not infrequently artificial, due, it may be, to the weight of the bismuth emulsion employed for purposes of definition. This is a point that has of late received a good deal of attention abroad, especially in France, where surgeons seemed to be agreed that the data afforded by X-rays in diseases of the stomach require to be accepted subject to caution.

Interesting as the results of radiographic examination may be in pleurisy, pericarditis, etc., their value is, speaking generally, merely scientific, since but rarely can the method be brought to bear in private practice, with which alone the " junior practitioner " is concerned.

We are surprised to find no mention of Meyer's delicate phenolphthalein test for blood in liquids and of Florence's pyridine zinc acetate test for urobilin, since these present many advantages over the classical reactions.

We can cordially recommend this work to all and sundry. It is invaluable as a work of reference for the practitioner confronted by a difficult case, who needs coaching for a further scrutiny. For the student it is the necessary complement of ward work and direct observation. It is copiously and appropriately illustrated, and no expense has been spared in the matter of colour plates when the nature of the subject rendered this desirable.

ELECTRO-THERAPEUTICS. (a)

DR. HUMPHRIS has written a very useful book. There are many English manuals on the uses of electricity in medicine, but Dr. Humphris scarcely trespasses on their grounds. In the preface the author states that his volume is in no sense a text-book on electrotherapy, that his aim is to convey clear information as to some useful form of electrotherapy. All the facts narrated are, he emphasises, based on personal experience. A perusal of the book confirms these statements of its author. None of the physics of electricity which we are accustomed to find fully described in medical works on electricity are mentioned here. But, on the other hand, we find fuller directions as to the methods of employing electricity than we are accustomed to find in such manuals. Dr. Humphris is an enthusiast on the uses of static electricity, which has been so long neglected in our damp climate. Several practical methods of overcoming this drawback are metioned as having answered the test of experience. Illustrations of the various static modalities accompany the text. Nowhere do we remember to have seen so many useful diagrams accompanying the complete directions as to the means of application of the breeze, the brush, the spark, the static induced, and the wave current. We point out a slight error: in Chapter VIII., on the static induced current, it is stated in the text that "the wave current has already been described." We find, however, that the wave current is described at length in the succeeding Chapter IX. Electric light baths, thermo-penetration, and the high candlepower lamp, are described in other chapters. Very little is said about the value of the high-frequency current, as Dr. Humphris uses that current in comparison but rarely.

The second part of the book deals with various diseases and symptoms, such as pain, sciatica, rheumatism, lumbago, diseases of the alimentary canal, and enlarged prostate. The last methods of treatment of these troubles are described in detail, with illustrative cases.

A useful glossary and index complete the volume. The author is to be congratulated on having produced a book of so much practical value in so small a compass.

CONJUGAL HAPPINESS. (b)

THERE is little doubt that a fuller knowledge by the general public of the causes leading to happiness or the reverse in marital life would benefit not only those who are contemplating marriage or who are married but also their offspring and the race in general. We agree with the translator of the book before us that it is not one to be " placed in the hands of the young in its entirety," but its appearance may be welcomed by the class of the community above-mentioned. In its pages the author discusses fearlessly and plainly every factor that can possibly interact upon marital happiness, and he intends it to be a handbook of matrimony designed " quite as much, nay, even more, for those who intend to set their course for the port of matrimony as for those who have already reached it." To pessimists who deny the existence of happy marriages Dr. Loewenfeld replies that the rules laid down as to the relation of desires to happiness of any kind apply, generally speaking, to conjugal happiness as well. It is an old saying that "Les mariages se font au ciel, et se consomment sur la terre," but in order that this consummation may be effected it should not be left, as is so often the case, to blind chance to lead the way. The attainment of the priceless treasure of conjugal happiness will, surely, be facilitated by enlightening the contracting parties as to its manifold sources and as to the means to be taken to avoid the numerous pitfalls that beset the unwary. With regard to the sexual enlightenment of the young the opinion of the author may be gathered from the following: "As the present-day opinions in competent circles are agreed that even children of both sexes ought to be enlightened in these matters to a certain extent, the information being adapted to the comprehension at different ages and gradually widened in scope." In short, every principle of conduct for the guidance of the sexual life is discussed with restraint and common-sense, and, at the same time, other factors, such as religion, occupation, social status, finance, etc., are fully considered from their respective standpoints. We have pleasure in confidently recommending this book as a safe guide for the married or those about to marry.

THE CARE OF OLD AGE. (*a*)

The question asked in Ecclesiastes, "Why shouldest thou die before thy time?" is one that has interested many, but still remains as much of a mystery as ever. Indeed, the very meaning of the question is not yet definitely agreed upon, for though many are ready to accept the biblical three score and ten years as the normal life of man, there is much evidence for believing that this is an under-estimate. For the solution of the problem there is, perhaps, a greater mass of statistics than there is on any other subject, but these statistics cannot yet be used to give a final answer to the question. Till preventive medicine has succeeded in preventing preventable disease, and till the human body is saved from the many injuries that such disease inflicts, it is difficult to formulate what is normal old age. Metchnikoff, in his work on the prolongation of life, has put forward a fascinating hypothesis on this subject, based on the idea that a man is as old as his arteries, and that the age of his arteries largely depends on the poisons that damage them during life. His explanation of the generation of these poisons, and of the means of avoiding them, is not proven, and is probably not complete, but it is a good working hypothesis, and evidence seems to be accumulating in support of it. So long, however, as preventable diseases can scar and and sear the human frame, Metchnikoff's ideal is unattainable, and we must be content to try and preserve in health those who show signs of the wear and tear of life. Dr. Saundby has studied some of those conditions which present special features in old persons, and gives us admirable rules for the prevention and treatment of such. The book is interesting, and will well repay perusal.

LITERARY NOTES.

We have been favoured with advance proofs of a set of drawings of King's College Hospital, reproduced in photogravure from the originals by Hunslip Fletcher. The present sketches are in series with the admirable etchings of Guy's Hospital, by the same artist, which were noticed in these columns. Now that King's College Hospital is being removed from its ancient site, Mr. Fletcher's pictures have a special interest. The subjects chosen are (1) the front of the hospital, (2) the fine old staircase, and (3) the chapel. We are sure that King's men, past and present, have only to know of these beautiful pictures of their *alma mater* to purchase them freely. The publishers are Messrs. W. H. Benyon and Co. of Cheltenham.

No European health resort can compete with the famous spa of Harrogate, with its eighty springs, in the variety, and richness in mineral constituents of its waters. We have received a copy of the presidential address delivered before the Yorkshire Branch of the British Medical Association by Dr. Charles Gibson, J.P.,, on "A Plea for Harrogate and other English Health Resorts." There is no better equipped bathing establishment in the world than Harrogate, which might well be termed a family spa, and there is little doubt that if the famous health resort were better known on the Continent, and its merits properly appreciated, foreign medical men might recognise its advantages and send their patients in legions. Radioactivity as a chemical property of water is gradually becoming more understood, and this peculiar quality belongs to certain of the springs at Harrogate.

MEDICAL NEWS IN BRIEF.

Non-Panel Doctors.

It is reported that the London Medical Committee has decided to recommend the formation of an Association of Non-Panel Doctors for the County of London, who will not accept service under the Insurance Act unless the following amendments are incorporated in the Act:—Free choice of a doctor; an income limit; no one section to have a permanent majority on any Insurance Committee; and medical discipline to be in the hands of the Medical Committee.

In many parts of London there are already local non-panel societies, and the London Medical Committee will act as the central co-ordinating body. Communications should be addressed to the Secretary of the London Medical Committee at 45 Welbeck-street, W.

Model Dwellings and Infant Mortality.

The annual meeting of the Metropolitan Association for Improving the Dwellings of the Industrial Classes was held last week at 1 Pancras Square, Mr. Julian Hill presiding. The report showed that among the occupiers of the Association's 14 blocks of dwellings in various parts of London the rate of mortality was 12.57 per 1,000. In the entire metropolitan area the rate was 13.6. The deaths of occupiers' children under one year were at the rate of 76 in every 1,000 births, while those in the entire metropolis were at the rate of 91 per 1,000. The births were at the rate of 20.9 per 1,000 of the whole population of the dwellings, that for the whole metropolis being 24.5.

Apenta Water in West Africa.

Prof. Dr. Kulz, German Imperial Government Physician, Cameroons, has just reported his experience in West Africa of the aperient Apenta Water. He remarks that he has always given the preference to it in the West African tropics on account of its many advantages, especially in hot climates, as it is here that the European is predisposed to suffer from constipation, partly because of the loss of fluid from the skin, partly by change of diet, and partly as a sequel to the most prevalent of tropical maladies—malaria. He testifies that Apenta has proved itself a mild but reliable aperient, free from unpleasant after effects, and one which patients take readily; and as the water has been found to bear well the heat of the tropics, it is one of its great advantages.

Free Lectures to Medical Men and Students.

A course of ten lectures up "Electrocardiography and Heart Sound Records" will be given by Dr. Thomas Lewis at University College Hospital Medical School, at 11 a.m., on Tuesdays and Fridays of each week, commencing Friday, July 25th. The lectures will include anatomical demonstrations of the latest

---

(*a*) "Old Age, its Care and Treatment in Health and Disease." By Robert Saundby, M.D.Edin. 8vo. pp. viii. and 312. London: Edward Arnold. 1913.

discoveries in the anatomy of the heart, and full and illustrated descriptions of the several disorders of the cardiac mechanism (sinus arrhythmias, extra-systoles, paroxysmal tachycardia, heart-block, auricular fibrillation and alternation). Descriptions and demonstrations of the apparatus used for electro-cardiographic purposes, normal heart sounds, heart sounds in mitral stenosis, and other clinical conditions will be given. These lectures are free to all qualified medical men and medical students on presentation of visiting cards.

Small-pox in New South Wales.

Telegrams from Sydney report a mild epidemic of small-pox, thirty persons having been placed in quarantine. None of the cases, however, are of a serious character. Two factories have been closed, and free vaccinating depôts have been established. Some of the steamship companies are insisting upon outgoing passengers being vaccinated.

University of Oxford.

The following degrees have been conferred:—

M.Ch.—E. L. Pearce Gould, Christ Church.

B.M.—N. F. Hallows, Keble; A. L. Pearce Gould, Christ Church; D. B. I. Hallet, University; W. H. Ogilvie and F. A. Hampton, New College.

University of Durham—Faculty of Medicine.

The following degrees were conferred during June, 1913:—

Doctor of Medicine.—Wilfred Barkes, M.B., B.S. Durh., George E. Lloyd, M.B., B.S.Durh., George C. M. M'Gonigle, M.B., B.S.Durh., Matilda A. Sinclair, M.B., B.S.Durh.

Doctor of Medicine for Practitioners of Fifteen Years' Standing.—James W. Alexander, M.R.C.P. and S., L.F.P.S.Glas., Michael B. Foster, M.R.C.S., L.R.C.P., D.P.H., James M. Handy, L.M. and S. Ceylon, Edward T. Macintyre, L.R.C.P. and S., L.F.P.S.Glas., L.M. and S.Ceylon, Richard Price, L.R.C.P. and S., L.F.P.S.Glas., Reginald C. Tweedy, M.R.C.S., L.R.C.P.

Bachelor of Medicine (M.B.).—Edgar Babst, Robert E. Bell, Garfield Carse, Harold Fairclough, Ah Chit Jap, M.R.C.S., L.R.C.P., Robert L. Kitching, George E. W. Lacey, Claude W. Morris, M.R.C.S., L.R.C.P., Nora Murphy, Carinna A. B. O'Neill, Edward Phillips, John L. Pringle, Cedric O. Shackleton, James S. Soutter, M.R.C.S., L.R.C.P., Gordon S. Woodman.

Bachelor of Surgery (B.S.).—Edgar Babst, Garfield Carse, Harold Fairclough, Ah Chit Jap, M.R.C.S., L.R.C.P., Robert L. Kitching, George E. W. Lacey, Claude W. Morris, M.R.C.S., L.R.C.P., Nora Murphy Carinna A. B. O'Neill, Edward Phillips, John L. Pringle, Cedric O. Shackleton, James S. Soutter, M.R.C.S., L.R.C.P., Gordon S. Woodman.

Bachelor of Hygiene (B.Hy.) and D.P.H.—Ernest E. Norman, M.B. B.S.Durh.

Licence in Dental Surgery (L.D.S.).—William Hutson.

Conjoint Examinations in Ireland.

The following candidates have passed the Preliminary Examination of the Royal College of Physicians and the Royal College of Surgeons, June, 1913:—

D. J. Baldwin, A. H. Boyd, A. J. Crean, M. Donohoe, G. E. Evans, W. Fielding, W. Flynn, S. A. Gailey, Miss Ella Gleeson, W. F. Hughes, M. J. Hunt, Miss C. E. Kyle, A. F. Mallon, A. McCambley, R. G. C. McCullagh, E. D. Nolan, R. V. O'Connor, M. J. O'Riordan. Miss H. G. Rea (with Honours), P. J. Sheerin, A. A. Townsend, S. T. Wills.

Third Professional Examination, June 1913.—A. P. Adams, S. Barron, W. P. Cooney (Honours), J. Dwyer, H. Fitzgibbon, E. G. Foley, S. E. Gordon, J. W. E. Graham, E. N. H. Gray, O. K. Kerrigan, M. J. Loftus, W. G. McConnell, M. Moran, T. O'Donoghoe, L. S. O'Grady, G. M. C. Powell, L. M. Rowlette, R. A. Ryan, T. J. Ryan, T. H. Sarsfield, H. Scher, J. A. Watson.

Final Examination, June, 1913.—Patrick Ashe, John D. Cherry, Dominic F. Curran, Hugh A. S. Deane, James Devine, William St. Leger Dowse, Thomas R. Elliott, Thomas Grey, Aloyzius Humphreys, James Kearney, John Kelly, Francis P. Kennedy, Frederick J. M. Kennedy, William J. P. Lillis, Robert J. May, Patrick M. Moriarty, Edward J. B. Moynihan. Bartholomew J. Mullin, Daniel Mullin, Bernard Murphy, Charles McDonnell, Thomas B. Newman, Bernard J. O'Donnell, George E. Pepper, Robert Slaney, Trevor Seymour Smith, Geoffrey N. Smyth.

Trinity College, Dublin.

The following Candidates have passed the Preliminary Scientific Examination, Trinity Term, 1913:—

Botany and Zoology.—Alexander R. Barlas, Harry L. Parker, Joseph R. Brennan, Stanley C. Mitchel, Wilfred V. Pelissier, Edward D'A. McCrea, Robert W. Nesbitt, William P. Elford, George W. B. Shaw, Frederick C. Tucker, Frederick J. Smith, James H. B. Levis, Thomas Mulock Bentley, Isabella M. Alexander, James Beasly, Philip C. Cowan, Andrew H. Davidson, Michael Dippenaar, William A. Byrn, William H. Flinn, Henry J. Rice, Willem P. Lubbe, Dermot F. J. Falvey, Arthur G. Bewley, Arthur L. Gregg, David L. H. Moore, Arthur A. Morphy, John W. Duggan, Eric E. Tivy, Ethel M. Luce, Edward Evans, Daniel McElwee, John M. Semple, George F. Dobbin, Harry Banks, Richard M. B. Gamble, Kenneth Green, Thomas H. R. McKiernan, Philip S. Snell, James C. Campbell-Henry, Rita Henry, John B. McGranahan, Eric J. Lyndon, Percy C. Parr, Johannes C. Fouché, Frederick Gill, Henry Hanna, Joseph Power, George E. Healy, Jason G. Bird, George C. Ballantine, Herbert W. McAuliffe.

Physics and Chemistry.—Norman L. Bor, William H. Flinn, Alexander R. Barlas, Francis G. Pratt, George W. B. Shaw, Edward D. A. McCrea, Philip S. Snell, Charles P. Chambers, William R. Burns, Andrew H. Davidson, Paul C. Hallowes, James Beasley, Hirsh Brill, Paul H. S. Smith, Bryan A. MacSwiney, Margaret Wolfe, John R. Duggan, Marie A. Hadden, Alan G. Wright, Thomas E. Hill, Arthur L. Gregg, Willem F. Wicht, William T. Collins, Hastings H. Molloy, William J. Hamilton, Walter A. Bullen, Edward H. Powell, Millicent Hamilton-Johnstone, Cecil F. Kennedy, Thomas W. Panter.

Preliminary Scientific Dental.—Sidney A. Clark, William B. Parr.

Dental Anatomy.—Sidney G. Clark, William B. Parr, Louis E. Wigoder, Charles H. Herbert, Maurice L. Counihan, John H. J. Stuart.

Intermediate Medical (Part I.) Examination.—Robert C. B. Ramsay, Joseph W. Bigger, Alan F. Grimbly, Thomas J. Lane, Clotilda B. Bevis, Charles O. J. Young, Eric E. Beatty, Frederick J. Murphy, Francis W. O'Connor, Roland H. Graham, Eileen G. Glenn, John J. Keating, William Hunt, Samuel R. Hill, John T. Westby, Benjamin D. Merrin, Thomas W. Sweetman, Alfred H. Price, Thomas G. Roche. Purser Medal.—Joseph D. Bigger. Cunningham Medal.—Robert C. B. Ramsay.

Intermediate Medical Examination.—Part II.—Eugene J. MacSwiney (passed on high marks), Henry V. FitzGerald, Herbert Mitchell, Richard O'Kelly, William J. Dowling, Edmond Robinson, David S. Martin, Chistopher C. Albertyn, Sidney W. Fisher, Cecil G. Sherowitz, Edward Mannix.

Final Medical Examination.—Part II.—Surgery.—William J. Merrick, David L. McCullough, David H. Hadden (passed on high marks); William F. Evans, Henry B. F. Dixon, Mabel A. Dobbin, Hedley Boyers, John G. Butt, William F. Gibson, Charles P. Kelly, Charles O'Reilly, Eleanor Taylor.

Final Medical Examination.—Part II.—Midwifery.—William H. R. McCarter, Henry L. D'O. Duckwood, John T. McCullagh, Ralph J. R. Mecredy (passed on high marks); Joseph A. Quin, John D. Oliver, William Foot, George B. Hadden, Rupert C. Lowe, Hawtrey W. Browne, Joseph C. A. McCalden, Charles P. Kelly, Herbert E. Murray, Thomas V. Oldham.

NOTICES TO CORRESPONDENTS, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial,* and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Contributors are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Reprints.—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

THE STATUS OF THE MEDICAL PROFESSION IN ONTARIO.

It is reported that the Ontario Government will appoint a Commission to consider the status of the medical profession in Ontario, the condition of medical education, the claims of the various medical schools to public support, and the demands of certain new schools to recognition as legitimate practitioners.

Dr. K. W. (Kent).—The "Zeistic" theory of the production of pellagra appears now to be superseded owing to the discovery of the *role* played by the biting-fly *Simulium* in its ætiology. More details still require to be worked out in this connection.

THE LATE SIR JONATHAN HUTCHINSON'S WISH.

Sir Jonathan Hutchinson, we understand, expressed in his will the desire that upon his gravestone should be inscribed the words:—"A man of hope and forward-looking mind."

"Ne Plus Ultra" (Hendon).—The value of a degree in science to a medical man depends a good deal upon his future line of work. Many consulting physicians hold such degrees and it is generally acknowledged that the possession of the B.Sc. or the D.Sc. stamps its owner as one who has done some good original scientific work.

SAFETY FROM LIGHTNING.

To the Editor of The Medical Press and Circular.

Sir,—Safety from lightning is easily secured, says the "Scientific American Journal," by putting on rubber over shoes and standing so your clothing does not touch anything.

I was rather surprised that no mention was made of this in the paper on deaths from lightning that appeared in your columns a few weeks ago.

Yours very truly,
J. E. Burton.

SHAMMING ILLNESS UNDER THE INSURANCE ACT.

One of the serious effects of hurried legislation is shown by a large section of the public, now that they are entitled to free medical advice, 75 per cent. of whom are reported to be receiving medical treatment under the Insurance Act, although in no need of treatment.

Appointments.

Fawcitt, R., M.B., Ch.B.Edin., Certifying Surgeon under the Factory and Workshop Acts for the Broughton-in-Furness District of the county of Lancaster.

Griffiths, Philip Rhys, M.B., B.S.Lond., Referee under the Workmen's Compensation Act, 1906, for the County Court Circuit, No. 24, to be attached more particularly to the Cardiff and Barry County Courts.

King, W. G., Colonel, I.M.S., Lecturer in Applied Hygiene of the Tropics to King's College.

Lloyd, Bertram A., M.B., B.S.Lond., F.R.C.S.Eng., Surgeon to the Out-patients at the Queen's Hospital, Birmingham.

McClelland, R. S., M.D.Edin., Certifying Surgeon under the Factory and Workshop Acts for the Pontyberem District of the county of Carmarthen.

Metcalfe, James, M.D.Brux., L.R.C.P. and S.Edin., Honorary Physician in Charge of the X-Ray and Electrical Department of the Prince of Wales's General Hospital, Tottenham, N.

Monro, Thomas Kirkpatrick, M.D., C.M.Glasg., Professor of Practice of Medicine in the University of Glasgow.

Mowat, Harold, M.D.Edin., Physician in Charge of the X-Ray and Electrical Department at the Metropolitan Hospital.

O'Brien, W., M.B., Ch.B.N.U.I., Certifying Surgeon under the Factory and Workshop Acts for the Aughrim District of the county of Wicklow.

Sinclair, J., M.D.Durh., M.R.C.P.Lond., M.R.C.S.Eng., Chief Medical Officer to the Post Office.

Steele, Russell Vyvyan, M.B., B.S.Durh., House Physician at the West London Hospital.

Vesselovsky, Victor, M.R.C.S., L.R.C.P.Lond., Resident Assistant Anæsthetist to St. Mary's Hospital.

Vacancies.

Worcester General Infirmary.—House Physician. Salary £120 per annum, with board, residence, and washing. Applications to William Stallard, Secretary, Worcester Chambers, Pierpont Street, Worcester.

North Wales Counties Asylum, Denbigh.—First Assistant Medical Officer. Salary £275 per annum, with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent.

University of London, King's College.—Demonstrator in the Department of Anatomy. Salary £100 per annum. Applications to the Secretary of the College.

Whitehaven and West Cumberland Infirmary.—Resident House-Surgeon. Salary £120 per annum, with board and lodging. Applications to H. J. Bewlay, Secretary.

Southwark Union, London.—Assistant Medical Superintendent. Salary £150 per annum, with board, lodging, and washing. Applications to Sydney Wood, Clerk, Union Offices, Ufford Street, Blackfriars, S.E.

Canterbury Mental Hospital, Canterbury.—Assistant Medical Officer. Salary £160 per annum, with board, lodging, washing, and attendance. Applications to the Medical Superintendent.

Peamount Sanatorium, Hazelhatch, Dublin.—Resident Medical Superintendent. Salary £400 per annum, with house and light included free. Applications to Hon. Secretary, 59 Fitzwilliam Square, Dublin.

County Asylum, Whittingham, Preston, Lancs.—Assistant Medical Officer. Salary £200 per annum, together with board, furnished apartments, and washing. Applications to the Medical Superintendent.

Down District Lunatic Asylum.—Junior Male Assistant Medical Officer. Salary £130 per annum, rising by annual increments to £150, with full rations, etc. Applications to the Resident Medical Superintendent. (See advt.)

Births.

Evans.—On July 3rd, at Floriana, Malta, the wife of Major C. R. Evans, R.A.M.C., of a son.

Heywood.—On July 5th, at Cornermead, Newbury, to Dr. and Mrs. W. B. Heywood—a daughter.

Woodward.—On June 28th, at Kingston Bagpuize, Abingdon, to Dr. and Mrs. Woodward—a son.

Marriages.

Langmead—Gray.—On July 3rd, at St. Ethelburga's, Bishopsgate Within, Frederick Langmead, M.D., F.R.C.P., of 53 Queen Anne Street, Cavendish Square, W., son of Mr. and Mrs. William Langmead, Sunnyside, Littlehampton, to Olive, youngest daughter of the Rev. Thomas T. Gray, Senior Fellow, Trinity College, Dublin, of 35 Trinity College, Dublin, and Carn Park, Co., Westmeath.

McMullan—Wells.—On July 1st, at St. Agatha's Church, Brightwell, Dr. George McMullan, of Wallingford, to Muriel Watkins, second daughter of Mr. and Mrs. Henry Wells, of Sotwell Hill, Wallingford.

MacNalty—de Wesselow.—On July 1st, at St. Martin's Church, Epsom, Arthur Salusbury MacNalty, M.D., M.A., M.R.C.S., eldest son of Dr. F. C. MacNalty, of Winchester, to Valentine Dorothea Vaughan, only daughter of tho late Rev. C. H. Simpkinson de Wesselow and of Mrs. Simpkinson de Wesselow, of Ebbisham House, Epsom.

Powell—Barrass.—On July 2nd, at St. Peter's, Harrogate, Major John Powell, R.A.M.C., Egyptian Army, Cairo, eldest son of the late John Clark Powell, Blackrock, Co. Dublin, and Mrs. Powell, Tentore, Bexhill, to Elsie Kate Barrass elder daughter of the late Matthew Barrass, Killingworth, Northumberland.

Rivington—Willans.—On July 5th, at St. George's Church, Hanover Square, London, Harold Victor Gibson, youngest son of the late Walter Rivington, Esq., B.A., M.B., M.S., F.R.C.S., to Charlotte Mary Eveleen (May), only daughter of the late John W. Willans, Esq., J.P., of Leeds.

Stansfeld—Squire.—On July 3rd, at Holy Trinity Church, Leicester, Alfred Ellington Stansfeld, M.A., M.B., M.R.C.P., of 48, Bryanston Street, London, W., eldest son of Alfred Stansfeld, of London, to Helen Mary, daughter of Samuel and Annie M. S. Squire, of 1 Salisbury Road, Leicester.

Deaths.

Cross.—On June 30th, at Calstock, Moss Lane, Pinner, John Cross, M.D.Cantab., formerly of Regent's Park, London.

Great Rex.—On June 30th, in a Nursing Home at Stoke-on-Trent, Adophus Burnell Great Rex, M.D., J.P. for county of Staffordshire, of Harecastle House, The Avenue, Kidsgrove, Staffordshire, aged 72. In practice for over fifty years at Kidsgrove.

Kloster.—On June 28th, at Kamaran, Arabia, Olaf Kloster, M.B., C.M.Edin., in his 47th year.

Rees.—On June 22nd, at Brynderw, Llanwrtyd Wells, suddenly, of syncope, William Thomas Rees, M.R.C.S., etc., in his 51st year.

Mariette.—On July 5th, at Peppard Common, Ernest Mariette, M.B.Lond., late of Plymouth and Colwyn Bay, eldest son of the late Prof. Alphonse Mariette, aged 52.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, JULY 16, 1913. No. 3.

NOTES AND COMMENTS.

The Sackville Probate Verdict and "Undue Influence."

ENGLISH law is founded upon an endless accumulation of precedents. So far as the principle of "undue influence" in the obtaining of gifts or legacies is concerned, an important decision has been added in the recent probate suit brought by the Scott family against Lord and Lady Sackville. The disputed will left to Lady Sackville cash and property to the value of half a million of money. In addition, large sums of money were also given to her by the testator, the late Sir John Scott, during his life. Undue influence and fraud were alleged against Lord and Lady Sackville. The allegation of fraud appears to have rested on a flimsy foundation, and was practically dismissed by the judge. The other point, that of undue influence, was also unsustained, as the terms of the will were upheld, and a verdict returned in due course to that effect in this remarkable suit. With the general aspects of the case we are not, as a medical journal, specially concerned. The point of "undue influence," however, has a bearing upon the medical profession that it may be well to discuss briefly. So far as the term was popularly understood it seemed to deal with those cases in which persons, not being family relatives to a testator, had during life obtained such an ascendancy over the latter as to secure either considerable gifts during life or legacies after death. In various ways the special provision seemed of considerable value in the protection of the natural interests of relatives, and in securing a just disposition of property. The Scott-Sackville trial, however, shows that it is quite possible for a person, not being a family relative of a deceased testator, to receive large gifts during life and still larger sums by way of legacy without overstepping the limits of due and legitimate influence.

The Medical Bearing.

THIS decision affects members of the medical profession, inasmuch as from time to time valuable gifts and valuable legacies accrue to them from patients. In the past certain lawsuits brought by the relatives of such deceased donors and testators have been decided in their favour. As a result it has been a fairly well accepted view amongst medical men that it is exceedingly unsafe to accept such gifts and unwise to regard such legacies as stable and valid. The Sackville decision, however, appears to have thrown a fresh complexion upon the legality of such transactions. In that case a lady, not being a family relative of deceased, has received large sums of money both before and after the testator's death, with the sanction of a British jury, who took twelve minutes only in arriving at their verdict. The practical conclusion seems to be that a medical attendant, who obviously has it in his power, as a rule, to render solid and, it may be, incalculable services to the donor or testator, may in future regard the acceptance of gifts or legacies with a greater sense of security than has been heretofore possible. At the same time, it is wise to remember the saw that circumstances alter cases, and that a jury may be inclined to adopt a different standard in the case of a medical attendant from that applied by them to a society dame. From a psychical standpoint it is open to doubt whether a fully sane and responsible person should desire to leave the bulk of his fortune away from his blood relations. In most civilised countries an alien disposition of the kind is forbidden by law. Why should it be otherwise in the United Kingdom?

Tuberculosis in the Isle of Wight.

THE Isle of Wight, famous for its natural beauties and for its healthfulness, is not a place one would associate with consumption. Yet the annual report of the Medical Officer, Dr. J. Pixton Walker, shows that 225 cases were notified during the year 1912. He is able to add, however, the reassuring statement that the figures are 45 below the average of England and Wales for a population of similar size. The total deaths from tuberculosis for the year were 129, of which 102.4 were pulmonary and 26.6 other tuberculous disease. It is satisfactory to note that the returns for 1912 are little more than half those for 1901—in the earlier period they were 147 pulmonary and 29 other forms, or a total of 176, against 78, 20; and a total of 98. The administration of sanatorium benefit has been commenced by the Isle of Wight County Insurance Committee. Until recently no arrangement had been made for the provision of hospital or dispensary treatment of sufferers from the disease. Domiciliary treatment, on the other hand, has been granted to a number of patients, this comprising medical attendance, medicines, medical appliances, tuberculin and extra food. The Committee has now taken advantage of the fact that the National Hospital for Consumption, at St. Lawrence, has become a recognised institution under the Insurance Act, and is prepared to accept 12 advanced cases at a charge of 10s. 6d. each per week, inclusive of laundry and extras. In considering the facts of tuberculosis in the island, it must be borne in mind that not a few sufferers are attracted thither by the healthfulness of the climate, and after a year's stay are classified as residents. For all that, it is to be deplored that so lovely a spot and so fine a climate should be fated to harbour any consumptives at all. The steady decrease of the disease in the Isle of Wight is most satisfactory, and highly creditable to the local sanitary administration, besides which it may be regarded as a happy omen of the ultimate disappearance of this preventable malady.

LEADING ARTICLES.

THE AMALGAMATION OF ST. GEORGE'S AND WESTMINSTER HOSPITALS.

An event of much significance to the hospital world generally is the amalgamation announced last week between the two famous London hospitals St. George's and Westminster. Both institutions have occupied sites of great and increasing value, a fact that is attested in overwhelming fashion in one instance, for the ground upon which St. George's Hospital stands has been sold for the enormous sum of £480,000, subject to some slight reservations in favour of the Duke of Westminster. The principles involved in this amalgamation have a significance far beyond their mere local application, and some deserve careful consideration in view of the manifold changes which the medical profession may be called upon to face in a somewhat near future. It has in former times been customary to locate the great general hospitals of the metropolis within a comparatively small central area. Whatever may be said in favour of that practice in the past, it is certainly not so definitely desirable under modern conditions of transit and City life. The rapid growth of London has surrounded the central area with the rapidly increasing zone of densely populated suburbs included in Greater London. The great central hospitals, therefore, become more and more aloof from the crowded suburbs; while, for the same reason, their patients are subjected to a polluted city atmosphere. At the same time the vast increase in land value prevents the extension of hospital premises to meet increased pressure upon space; whereas, on the other hand, the sale of valuable City sites would provide not only ample room, but a handsome margin of endowment for the purposes of the charity. As to the question of amalgamation, it goes without saying that an opportunity is thus afforded in most cases of effecting a considerable economy of management. The present state of the voluntary medical charities—not only of the metropolis, but also of the United Kingdom—is simply chaotic. Every such institution is a law unto itself as regards its internal laws, its finance, and its administration. A Government inquiry into the state of the voluntary medical charities would probably reveal many weak points that might be rectified with advantage to the medical profession and to the outside public, who provide the funds for carrying on the hospitals and furnish the patients to whom these institutions bring help and succour. Now that two great London hospitals have taken the enlightened step of amalgamating and of selling their central sites, it may be excusable to look for further progressive reforms in the same quarter. So rapidly have the views of practical men changed of late with regard to many of their professional relationships with the outside world that such questions as the remuneration of hospital staffs, the security of tenure, the multiplication of hospital appointments, the rate of promotion to senior posts, the nature of the necessary medical qualifications, the limitation of out-patient drudgery, and various other points that will readily occur to the minds of our readers, have, of necessity, been submitted to considerable revision. The question of the nationalisation of hospitals is in the air. It has been materially advanced by the introduction of the National Insurance Act, and there is much to be said in favour of the view held by some students of social problems that the only logical solution of the medical part of the national health problem will be found in some form of State administration of hospitals. In any case, the governors of St. George's and of Westminster Hospitals may be congratulated on the courageous way in which they have settled the momentous questions of sale of site and of amalgamation. The traditions of both these charities are ancient and honourable, and they have added many illustrious names to medical history and many notable contributions to medical science. It may safely be predicted that the present distinguished members of the honorary medical and surgical staffs will lose nothing in dignity or opportunity by the amalgamation of forces—especially now that the question of University life in London is approaching its inevitable settlement.

RESIGNATION OF THE STAFF OF A LONDON HOSPITAL.

The resignation of the whole staff of a London hospital is a matter that would arrest attention at any time. Coming as it does at a time of considerable unrest in the medical profession, such an occurrence is calculated to excite more than ordinary interest. The incident has taken place in connection with the Mount Vernon Hospital for Consumption and Diseases of the Chest, and the names of the honorary physicians and surgeons, some on the consultative and others on the active staff, are of a distinction that suffices to raise the matter to one of first-rate importance. The main, although apparently by no means the only, cause of this common resignation has been what is described as the arbitrary, and probably illegal, action of the management in the dismissal of two physicians from the Northwood Branch of the institution. The committee of management appeared to imagine they can act as sole arbiters of the tenure of contract with the members of the honorary medical staff—in short, that they can at any moment dismiss a physician regardless of the rules of the institution, or of the ordinary legal aspects attached to a contract of the kind. In this particular case the members of the staff are not the sort of men who will tamely submit to an injustice perpetrated on their colleagues any more than they are likely to raise an unnecessary complaint. The fact that they have resigned in a body might well give pause to the most arbitrary and irresponsible management. Indeed, the Secretary of the Hospital, Mr. Charles Johnston, has since written a letter to the *Times* putting forward some sort of a faint-hearted apology for the action of his committee. He admits the fact that two physicians at Northwood have been, as he delicately expresses it, "relieved of their duties." He impugns the accuracy of the resigning staff, however, in their description of this as a disciplinary measure, as the reference to a "summary dismissal" might imply. The explanation accorded by Mr. Johnston is that, owing to the impending sale of the site at Hampstead, the Northwood institution will in future be the only place available for beds, and it was felt that they should be under the care of the senior physicians. The board, according to this statement, considered themselves entitled to evict the Northwood physicians forthwith, in order presumably to prevent any possibility of future friction with their seniors. Surely, the right way would have been to ascertain the views of the medical staff as to any readjustment of service that might be required to meet the altered conditions. The most grotesque part of Mr. Johnston's letter is the suggestion that, as the Northwood beds will be greatly increased in number at a later date, the two junior physicians would be invited to return in the ordinary course of things. If the rules of the hospital admit the appointment of physicians in so lax a way as he suggests, they must stand in need of drastic revision. There is not a word of explanation of the extraordinary conduct of the committee in proceeding to the extreme step of dismissal without granting the request of the ordinary medical staff to confer with them upon the subject. There is a general denial of the request of the staff that "other matters" might be discussed at the same time. "The committee regret," he adds, "that so many members of the medical staff have appended their names to the letter of resignation, some of whom have done so without a full knowledge of the circumstances of the case." The latter insinuation does not mend matters, as it simply casts a gratuitous slur upon the medical signatories, whose names are a sufficient guarantee to their professional brethren that they would not lightly sign such a document as their letter of resignation. The truth of the matter appears to be that the committee is so inflated with a sense of its own dignity and importance that it has taken an arbitrary view of its powers, and has dismissed two members of its honorary staff in an unjustifiable, and probably also an illegal, manner. If the question be pushed to legal decision it seems not unlikely that they would come out of the matter in a somewhat sorry plight. The day when lay committees can ride roughshod over the ordinary rights of their medical staffs is fast disappearing. Happily, the powerful defence organisations of the medical profession have taken under their care the protection of the holders of unsalaried hospital appointments. Meanwhile the staff of the Mount Vernon Hospital have shown a good example of the way in which a dignified and decisive common protest should be lodged against the unfair action of a hospital management. Their joint letter of resignation addressed to the committee of the hospital will be found in our correspondence columns.

CURRENT TOPICS.

Duodenal Ulcer—A Personal Testimony.

The reports by medical men upon their own diseases are invariably instructive, if somewhat melancholy, for it is always helpful to have symptoms recorded by a trained observer. We publish elsewhere in our columns an interesting account, by Dr. Xavier Combes, of his personal experiences as a patient suffering from duodenal ulcer. The case-history is recorded with cold-blooded exactitude from the first moment in which matutinal epigastric pain was experienced down to the operation of posterior vertical gastro-enterostomy, which could no longer be postponed on account of recurring attacks of melæna of increasing gravity. It may be noted that the pain always coincided with stormy and rainy weather, while in hot weather the patient would enjoy periods of quiescence. The temporary relief of the pain by pressure and from the presence of food in the stomach coincides with the classic description of duodenal ulcer. Large doses of bismuth also caused the attacks to cease for a while. It is not known how atmospheric conditions influence the onset of the attacks, but such was the case with Dr. Combes. Like many another patient who postpones operation, it is only putting off the evil day, for it had to come, and, fortunately, it was completely successful. It is poor comfort to be told that one is "a splendid example of a typical duodenal ulcer," for our confrère, fearful lest any malignant change might have supervened upon his ulcer, could hardly help feeling anxious when informed that surgical measures were the only form of treatment. Dr. Combes is to be congratulated upon his excellent recovery, and also upon the succinct and accurate manner in which he has noted every symptom in his own case for the guidance of his fellow-practitioners.

Poisoning by Easton's Syrup Tablets.

Broadly stated, all forms of accidental poisoning demand careful inquiry with a view of their prevention by the State. Curiously enough the legislature is slow of action in such matters, for only recently, in spite of the long-continued requests and warnings of the Pharmaceutical Society, have such deadly hypnotic drugs as veronal been added to part one of the Poisons Schedule, while so simple a safeguard as the compulsory adoption of specially shaped bottles and packages for poisons has not been adopted. Many valuable lives are lost every year because the legislature has not dealt with this minor but nevertheless highly important detail of social legislation. An example of the apathy which refuses to learn from experience is the deaths which occur from time to time from accidental poisoning by Easton's syrup sold in tablet form. Children mistake the tablets for sweets, with results that are not infrequently fatal, as strychnia, one of the chief constituents of the syrup, is peculiarly fatal to those of tender years. It is surely not too much to ask that in view of the frequency of such accidents, Easton's syrup tablets should in future be packed in a three-cornered bottle with a bold poison label outside—or, better still, that responsible manufacturers should decline in future to sell Easton's syrup or other deadly drugs in tablets. So far as the syrup is concerned, it is readily dispensed in its liquid form, and its removal from the tablet lists would cause little inconvenience to the public, whereas, on the other hand, its retention constitutes an established danger. In a recent case at Huddersfield the Coroner remarked that similar occurrences were known to him.

The Importance of a Complete Examination of the Expectoration.

IT is a medical truism to state that failures in treatment are not seldom due to hasty or incomplete examination of the patient or to the omission to submit the blood or one of the secretions of the body to modern laboratory tests. In general practice it is often difficult to apply the refinements of bacteriological diagnosis in the sickroom; nevertheless, when this can be done the results will nearly always justify the extra trouble and expense. Some interesting cases were described by Dr. J. A. B. Hammond, of Shanklin (*a*), in which the importance is emphasised of a complete bacteriological examination of the sputum. The writer, in common with many practitioners, was content, up to two years ago, when having the expectoration examined, to know whether the tubercle bacillus were present or not, leaving it at that. A case occurred in his practice of a patient who was invalided home from India with signs of catarrhal pulmonary mischief, chiefly marked at the left apex. Repeated examination of the sputum for tubercle bacilli yielded negative results, but inoculated media gave an almost pure culture of the pneumococcus. An autogenous vaccine was made, and after seven injections had been given the symptoms and signs cleared up. In another case a lady presented every clinical sign of phthisis, and there appeared to be no doubt about the diagnosis, though the characteristic bacilli were not found. Inoculated media, however, showed the presence of large numbers of streptococcus longus, some pneumococci, and many micrococci catarrhalis. This case might well have been one in which tuberculin treatment would have been recommended, but the bacteriological examination of the sputum entirely negatived such a hypothesis. It is possible that many cases of suspected phthisis that do not react to tuberculin or other remedies might do so after injections of the appropriate autogenous vaccine.

The True Meaning of Sanatorium Benefit.

THE question as to what is exactly comprehended under the term "sanatorium benefit" under the National Insurance Act is one of considerable importance, both to the insured themselves and also to the medical profession. A thoughtful, if somewhat pessimistic, paper upon the subject was read the other day by Dr. Arthur Latham, at the Congress of the Royal Sanitary Institute at Exeter. The author doubted whether there was any district in England where there was an organised and coordinated scheme upon the lines of the Astor report in actual working order. It is true that the time is still short for the various local authorities to organise such schemes; but, on the other hand, it is poor comfort to be told that thousands of patients are receiving treatment at sanatoria when the utmost difficulty is often experienced, at any rate in London, to deal with the poor consumptive according to the original intention of the Act. Incurable tuberculous patients who have been refused admission into sanatoria might have been spared a good deal of disappointment by the use of some such term as "tuberculosis," instead of "sanatorium," benefit. The latter term has been made to include the provision of food, fuel, and clothing under its regulations. In this manner Public Health and Poor Law funds are being relieved, but the sanatorium benefit funds are becoming depleted. In consequence, the principal object of sanatorium benefit, the prevention of the disease, is being severely handicapped. Other speakers, who followed, maintained that the heart of the ideal scheme in fighting tuberculosis is the dispensary, which can be so organised that ample time can be given to every case. Under existing circumstances much importance is assumed by domiciliary treatment, and this can be so arranged that the general practitioner will be able to take his share in the scheme, for the whole ground cannot be covered in a comprehensive manner by Insurance Committees or dispensaries without the co-operation of the family doctor.

The Prevention of Puerperal Fever.

THE epoch-making researches of Semelweiss with regard to the incidence and prevention of puerperal fever have borne fruit by the further elaboration, since his time, of the principles of asepsis as applied to obstetrics. Nevertheless, in spite of every precaution, the parturient woman may become the victim of sepsis, which may confine itself to the pelvis or develop into the more alarming constitutional state of septicæmia. Happily, the latter event is fast becoming a thing unknown in our great lying-in hospitals, but now and then cases of puerperal infection occur in private practice, more especially where skilled medical aid has not been available at the time of delivery. An important effort has recently been made in Birmingham in connection with the prevention of infectious disease by the opening of a new ward to accommodate twenty-eight patients in the Birmingham and Midland Hospital for Women, which took place last week. Formerly, by arrangement with the City Council, two beds were reserved in the hospital for such cases, but the new arrangements will facilitate the treatment and the prevention of puerperal fever in Birmingham, where, it may be noted, the disease has been made notifiable. The new ward is quite isolated and self-contained, and it will be staffed by special nurses from the hospital staff.

Memorial to Sir Henry Swanzy.

IT is with satisfaction we learn that the citizens of his native city have taken steps to establish a memorial to the late Sir Henry Swanzy, and at an influential meeting held ten days ago, under the presidency of the President of the Royal College of Surgeons, the project was set on foot. One is too ready to think of a great surgeon, such as Swanzy, as if he were merely a great surgeon, and as if only the medical profession had a right to be proud of his achievements. This is a wrong attitude of mind. Not only is it the duty of the medical profession of the United Kingdom and the world to show its respect for what Swanzy accomplished in surgery, but it is incumbent on Ireland and Dublin to show their reverence for the memory of a great benefactor of his fellow-countrymen. In this spirit the leading representatives of the various interests and professions have gladly joined the executive committee for the purposes of the memorial. Fortunately, there is no difference of opinion as to the form the memorial should take. While the Royal Victoria Eye and Ear Hospital remains unfinished, Swanzy's life-work is incomplete.

Our Leaders.

IT is almost a truism that medicine to-day is run on more or less scientific lines. Science is our standard, and we are almost tired of the reiteration of the word. Yet in our community of scientists a strange paradox outstands. It is that professional leadership is often far removed from success in practice. The anomaly is so frequent and familiar

---

(*a*) *Guy's Hospital Gazette*, July 5th, 1913.

that we hardly notice it. It is certainly there and as certainly it should not be there. Bacon has been accused of many things, from embezzlement to Shakespeare. Whatever opinions we hold about these we can have no doubt that it is due to him that laymen are the real arbiters of a doctor's fate. He made inductive reasoning popular and with it the subversion of authority. Although he saw the danger of applying his method to things not physical his followers did not, and that is why a man who is out for popularity to-day can always gain a reputation. We do not specify the kind of a reputation, but to some men any reputation is better than none, especially when it includes pecuniary success. As long as we are servants of the public things will be as they are. To make sure that the best men reach the top we should have to hypothecate either an intelligent public or an entirely disinterested profession.

Roi Malgre Lui.

There are several obvious penalties attached to Royal birth. One of them is that the princes of the earth are only taken seriously in their capacity of being what they are. They are rarely allowed to do what they can. Medicine claims several Royal practitioners though only one of them, Duke Karl Theodor of Bavaria, attained any degree of success. He gave up his life to the charitable practice of ophthalmology to such effect that he was universally considered much more a surgeon than a prince. By sheer good work he left the cramped dignity of Royalty and became a man. He is the shining exception. The Queen of Greece's case is an example of the rule. She had a praiseworthy desire to help her country's sick soldiers, and went as a nurse to one of the military hospitals. Circumstances were too much for her. Sooner than ask their Queen for a drink of water the wounded men lay in thirst and loyal awe till some lesser mortal came along. So the Queen had to retire from active nursing and now substitutes patronage for personal service. It was the same long ago. James IV. of Scotland was an amateur dentist, and pursued his passion for the tooth, the whole tooth and nothing but the tooth, regardless of expense. The Royal cash accounts show expenditure on "turcases to take out teeth," and items of fourteen shillings "to ane fellow because the King pullit furht his tooth." James apparently practised dentistry only for amusement, and like Samson attained a reputation through manipulating the jawbones of asses.

The Forthcoming Oxford Ophthalmological Congress, 1913.

As already announced, the next meeting of the Congress will take place at Keble College, Oxford, on Thursday, July 17th, and Friday, July 18th, 1913. The members will meet informally at dinner at 7.30 p.m., in Keble Hall, Keble College, on Wednesday, July 16th. Members who propose to be present can be accommodated. A charge of 7s. 6d. *per diem* is made by the authorities for board and lodging in Keble College. The official dinner of the Congress will take place in Keble Hall at 7.30 p.m. on Thursday, July 17th, when the chair will be taken by Professor Sir William Osler, Bart., F.R.S. A discussion "On the Present Position of Ophthalmology" will be held at 2.30 p.m. on Friday, July 18th, at the Eye Hospital. It will be opened by the Master of the Congress, Mr. K. W. Doyne. Further details may be obtained from the Honorary Secretary, Mr. Sydney Stephenson, 33, Welbeck Street, W.

PERSONAL.

H.M. the King has been pleased to give directions for the appointment of Mr. Cyril Hartley Durrant, M.B. (Medical Officer), to be an Official Member of the Legislative Council of the Island of St. Vincent.

Sir Rickman J. Godlee has been re-elected President of the Royal College of Surgeons of England.

Mr. Harold Chapple, M.B., M.C.Cantab., has been appointed Obstetric Surgeon to Guy's Hospital.

Mr. W. H. Trethowan, M.B., M.S.Lond., has been appointed Orthopædic Surgeon to Guy's Hospital.

Dr. N. R. Phillips has been appointed Medical Superintendent of the County Asylum, Abergavenny.

Dr. G. H. Hunt, M.A., M.B., B.Ch.Oxon., has been appointed Fifth Assistant Physician to Guy's Hospital.

Dr. H. T. Depree, B.A., M.B., B.C.Cantab., has been appointed Honorary Anæsthetist to Guy's Hospital.

Dr. Stanley Wyard, M.D., B.S.Lond., M.R.C.P., has been appointed Pathologist to the Victoria Hospital for Children.

Mr. C. E. S. Jackson, M.B., B.S.Lond., F.R.C.S., has been appointed Surgeon to the West Norfolk and King's Lynn Hospital.

Sir Donald MacAlister, K.C.B., F.R.S., was the recipient last week of the Honorary Degree of LL.D. of Queen's University, Belfast.

Dr. Ralph M. Soames, M.B.Cantab., M.R.C.S., L.R.C.P., has been appointed Tuberculosis Medical Officer for the County of Surrey.

Mr. Evan Abraham Morgan, of Addison-road, Hove, physician and surgeon, left estate of which the net personalty has been sworn at £26,226.

Dr. F. S. Palmer, Physician to the West End Hospital, has been elected President of the West London Medico-Chirurgical Society for the ensuing year.

Among the recipients the other day of the honorary degree of LL.D. of the University of St. Andrews was Lieut.-Colonel Sir C. H. Bedford, D.Sc., M.D., I.M.S.

Dr. E. Graham Little has been re-elected a member of the Senate of the University of London by Convocation as a representative of the Faculty of Medicine.

At the last meeting of the Corporation of London the salary of Dr. F. J. Waldo, Coroner for the City and for the Borough of Southwark, was increased from £1,250 to £1,450 in recognition of his work in the City.

Mr. Charles Leedham Green, M.B., Ch.B.Birm., F.R.C.S., Surgeon to the Queen's Hospital, Birmingham, has been appointed Joint Professor of Surgery in the University of Birmingham in place of the late Professor Jordan Lloyd.

CLINICAL LECTURE
ON
THE TREATMENT OF GLAUCOMA, WITH PARTICULAR REFERENCE TO THE NEWER OPERATIONS. (*a*)

By SYDNEY STEPHENSON, S.O. (Oxon.)

THE treatment of glaucoma may be described as (*a*) first-aid, (*b*) surgical, and (*c*) palliative.

(*a*) FIRST-AID TREATMENT.

What has been called first-aid treatment may be required when the surgeon encounters a case of acute glaucoma, on which for one reason or another he is not prepared to perform iridectomy. For the temporary reduction of the intra-ocular pressure and its attendant manifestations several means are available. One of the latest is the subconjunctival injection of from five to fifteen drops of a 4.05 per cent. to 5.41 per cent. solution of sodium citrate, as advised by Dr. Martin H. Fischer (1), of the University of Cincinnati. The effects last for from three to six days or longer, and are accompanied, according to the experiences of those who have tried the method, by relief of all the subjective symptoms of glaucoma. The "colloid acidosis theory" of Fischer, upon which this method of treatment is based, has given rise to considerable interest in the United States. Very briefly, the eye is believed to become glaucomatous not because fluid is pressed into it, or prevented from escaping from it, but because it absorbs an increased amount of water, as the result of alterations in its colloidal condition.

Another way of relieving the intra-ocular pressure for the time being is by the performance of *posterior or equatorial sclerotomy*, a simple enough operation, in all conscience, and one well within the compass of the average practitioner. A narrow blade, such as a Graefe's cataract knife, is plunged meridionally into the sclera in the interval between the insertion of the superior and external recti muscles, or between the external and inferior recti, at a distance of at least 6 mm. from the visible edge of the cornea, so as to avoid the ciliary body. The cutting edge of the blade is directed away from the cornea. The blade is then turned upon its axis, to allow of the escape by its side of a little vitreous, and after having been once again turned into a meridional position, it is finally withdrawn from the eye. By pushing the ocular conjunctiva on the point of the knife before piercing the sclera, the operation may be performed, as it were, subconjunctivally.

Decompression is assured at all events for some days. As Dr. Louis Dor (2), of Lyons, has well said, in such cases, "equatorial sclerotomy is as urgent as the cutting of the rope of a hanged person."

The operation can be done without anæsthesia, general or local. Cocaine, indeed, helps but little, since the remedy is absorbed with difficulty, if at all, by a glaucomatous eyeball.

Pain, apt to be very severe in cases of acute glaucoma, may be relieved by the hypodermic injection of an adequate dose of morphine. Locally, physostigmine or pilocarpine should be instilled, and the addition of dionin hydrochloride (5 per cent. to 10 per cent.) often has an almost magical influence in calming pain, and may, indeed, allow morphine to be dispensed with.

(*b*) SURGICAL TREATMENT.

Ophthalmic surgeons are almost agreed that the best treatment of acute glaucoma is by iridectomy. (*b*) The results of that operation are very favourable. For example, Schmidt-Rimpler (3), who collated the results in 167 acute cases in the practice of seven Continental surgeons, found that improvement or arrest of the disease took place in 80 per cent. of the cases.

It is, however, quite otherwise as regards simple glaucoma. The point is brought out very clearly by Schmidt-Rimpler's Continental statistics (3). That observer collected figures dealing with 828 cases of glaucoma simplex treated by iridectomy from the practice of seventeen surgeons. Of that number, operation succeeded only in one-third (33.7 per cent.) and failed in two-thirds (66.3 per cent). It is obvious, too, that the *permanent* results would be smaller than that represented even by that exiguous figure. The Laska-Fuchs's figures dealing with this point (4), evidently collected with great care, call for a word of separate mention; of 39 cases, iridectomy improved sight or kept it stationary in 48 per cent., or somewhat less than one-half. In the successful cases, the observation was spread over a considerable time, as may be gathered from the statement that the mean period amounted to five years. Several of the successful cases had been followed up for ten years.

In happy cases, iridectomy acts in various ways. It is at once necessary to dismiss the idea that the incision actually opens up the blocked spaces of Fontana and the canal of Schlemm. In point of fact, the ligamentum pectinatum is seldom reached by the knife, to say nothing of the venous canal. Yet in successful cases iridectomy does act by opening up the normal channels of excretion. This is accomplished by the iris tearing away during the operation at what is normally its thinnest part, the root. Hence, the paramount necessity of performing in cases of chronic glaucoma not an ordinary iridectomy but what Mr. E. Treacher Collins (5) calls an "iridectomy-dialysis." The other way whereby iridectomy-dialysis may relieve glaucoma is by the formation of a filtering scar or cystoid cicatrix. One distinguished surgeon (6) has recently recorded his opinion, which is to the effect that "the formation of a filtering cicatrix holds out the best hope of alleviating chronic glaucoma." It is, moreover, possible, as supposed by Dr. Thomson Henderson (7), that there is a third way whereby the operation relieves chronic glaucoma, namely, by the edges of the cut iris, said never to cicatrise after iridectomy, acting as a supplementary exit for the aqueous humour into the veins of the iris. If this supposition be correct, the size and the peripheral character of the iridectomy should matter little, whereas most people hold that the exact contrary is the case.

The causes of failure, like those of success, are several in number. The most obvious (and unfortunately not the least uncommon) is inefficient performance of the operation. The surgeon either fails to make his incision in the right place, removes too small a piece of iris, or performs an iridectomy pure and simple instead of an iridectomy-dialysis. At the same time it must not be forgotten that in long-standing cases the iris and the cornea may be organically adherent at their periphery, so that even with the most correct *technique*, it becomes a physical impossibility to detach one from the other. The cause remains intact, and the consequence, in the shape of increased pressure, goes unrelieved. Herein lies the explanation of the widely recognised

---

(*a*) A lecture delivered on June 7th, 1912, to the Candidates for the Diploma in Ophthalmology of the University of Oxford (with additions).

(*b*) Col. R. H. Elliot, however, holds that trephining is preferable to iridectomy even in acute glaucoma.

fact, to wit, that iridectomy, nearly always successful in acute glaucoma, succeeds in less than one-half of the cases of chronic glaucoma. But there are other causes of failure. Owing to delayed re-formation of the anterior chamber after iridectomy, the crystalline lens may become adherent to the wound or it is possible that the sudden reduction in intra-ocular pressure brought about by operation may lead to the same result. When the wound heals in the former case the sub-luxated lens presses the ciliary processes and any iris that may be left against the ligamentum pectinatum in the region of the coloboma, and thus perpetuates the symptoms. Another cause for the persistence of symptoms after iridectomy in chronic glaucoma is to be found when part of the root of the iris is left behind, and becomes adherent to the corneal cicatrix.

The uncertainty of iridectomy to relieve cases of chronic glaucoma, known for many years, has led surgeons to devise other methods for the surgical cure of the disease. De Wecker, who believed that an iridectomy, when efficient, was so on account of the incision in the sclera, devised the operation of anterior sclerotomy. This operation, however, is nowadays usually reserved for cases which iridectomy has failed to relieve or for cases of hæmorrhagic glaucoma. Another substitute for iridectomy was introduced by de Vincentiis (8), who combined sclerotomy with scarification of the fibres of the ligamentum pectinatum in the angle of the anterior chamber left uncut by the sclerotomy. In this way the excretory channels for the intra-ocular fluid were directly freed. De Vincentiis's method is still the favourite one in certain Continental clinics. It is well spoken of by Dr. Josef Meller (9), Professor Fuchs' assistant, who describes the operation as simply consisting in the division of the tissues at the angle of the anterior chamber by means of a needle-like instrument introduced into the anterior chamber.

During recent years quite a number of operations have been introduced, the object of which is either to open up new channels for the escape of fluid from the eye or else to provide for its exit by means of a filtering scar. The underlying idea, however, is by no means new, and, for that matter, in some instances even the method itself has been forestalled by the earlier operators. The conception of a "cystoid" or "filtering" cicatrix led de Wecker, as already stated, to design the operation of sclerotomy in the year 1867, and there had been earlier attempts in the same direction by Charles Bader. The late Professor Maklakow (10) many years ago described an operation to which he gave the name of "sclerotomia obliqua," and which was clearly meant to secure a filtering cicatrix. In a communication presented to the Eighth International Ophthalmological Congress, held in Edinburgh, in 1894, the late Mr. George L. Walker (11), of Liverpool, described his experiences with various plans for the surgical treatment of chronic glaucoma, and they furnish interesting reading in the light of the procedures introduced since then (*Transactions*, p. 315). Walker had endeavoured, although without success, to produce such a fistula by passing setons into the base of the anterior chamber, but he finally managed to make a permanent fistula by inserting a conjunctival flap into an incision in the anterior chamber, and leaving it to heal *in situ*. Walker shrewdly surmised that the rude iridectomies of earlier days were more efficacious in relieving tension than the more modern ones, since in the first-named the iris often prolapsed or the wound included a tag of conjunctiva in its healing. In either case a fistula, temporary or permanent, was the result.

The reaction against simple iridectomy in chronic glaucoma has gone to such lengths in certain quarters that I have heard a good authority express his conviction that, in the present state of our knowledge, we are scarcely justified in performing the operation. This somewhat extreme statement conveys, to my mind, more than the proverbial grain of truth.

THE MODERN OPERATIONS FOR CHRONIC GLAUCOMA.

1. Lagrange's operation, or "Sclerecto-iridectomy," first described in May, 1907, is as follows (12):—Physostigmine is dropped into the eye half an hour before operation, which is undertaken under the combined anæsthetic influence of cocain and adrenalin. The sclera is punctured with a narrow blade at a distance of 1 mm. from the limbus, and the counter-puncture is made at a corresponding point on the other side, and the intervening sclera is divided well back of the irido-corneal angle. During this process the cutting edge of the blade is directed backwards, so as to bevel the sclera, like the mouth-piece of a flute, and, finally, in terminating the incision, a large conjunctival flap is fashioned with the knife. The conjunctival flap is raised by means of forceps, and thrown back over the cornea, so as to expose the wound. An adequate piece of the sclera is then removed from the lip left attached to the cornea. In the next step iridectomy is performed in the usual way. Finally, the parts are covered with the flap of conjunctiva.

The instruments include those ordinarily employed for iridectomy, with the addition of a small pair of deeply curved scissors, which should be in good cutting order, since, as every surgeon knows, the sclera is a resistent structure.

Lagrange claims that his operation results in the formation of a filtering cicatrix without any entanglement of the iris.

2. Elliot's "Kerato-sclerectomy" was first described in December, 1909, in the columns of the *Ophthalmoscope* (13). Elliot had then performed it fifty times. It essentially consists in removing a disc of sclera and cornea close to the limbus, and in covering the parts with a flap of conjunctiva. By these means, it is believed that a permanent communication is established between the anterior chamber, on the one hand, and the subconjunctival tissue, on the other, so that the aqueous humour contained in the first-named may enjoy free exit.

It is performed under the local influence of cocain and adrenalin, and, in certain cases, a hypodermic injection of morphine is given twenty minutes beforehand.

The following account of kerato-sclerectomy is taken from Elliot's latest communication (14), as well as his recently published book (15), supplemented by the account given by Mr. E. Temple Smith (16), who spent some time in Madras for the purpose of studying Elliot's methods.

After most careful irrigation of the conjunctival sac with sublimate, 1:3,000, followed by salt solution, 1.4 per cent., and the use of a 4 per cent. solution of cocaine hydrochloride, re-inforced by adrenalin, 1 : 1,000, the patient is ready for operation. A large more or less triangular flap is dissected up from above the cornea. Great attention should be paid to its position. When correctly made, it runs concentric with the cornea at its lower ends, and terminates on either side about 4 mm. below the highest point of the cornea and at the same distance from the inner and outer sides of the limbus. This flap is dissected right up to the limbus, and, indeed, a little into the cornea, a point on which Elliot lays the greatest stress. This was done until recently with the point of the closed scissors, but Elliot, following the example set by Captain Hingston, I.M.S., now uses as a routine measure an ordinary Bowman's needle for separating the conjunctival layer from the deeper parts of the cornea. The dissection is to be continued until a thin, dark-coloured crescent, about 1 mm. in breadth, surrounds the base of the flap, and affords evidence that the cornea has actually been "split." That part of the denuded area selected for the application of the trephine is cleared from loose tissue with the point of the scissors. The trephine is next applied as close as possible to the limbus, only just clearing the conjunctival flap, and in such a way that a portion of the circle to be removed, say, from $\frac{1}{4}$ to $\frac{1}{3}$ of its area, shall consist of clear corneal tissue (E. Temple Smith) (16). A few quick, light turns of the instrument cause the cutting end to "bite," after which it is lifted from time to time, so as to ascertain progress. That the trephine has penetrated the sclero-cornea is shown by three points:—(1) By the welling up of aqueous; (2) by a curious sucking sensation experienced by the surgeon; and (3) by indications of slight pain on the part of the patient. Should iris bulge through the trephine hole (which happens in about one-half of the cases), it may be snipped radially with scissors, in order to allow the aqueous to escape from the eye. Should the fluid even then not find exit, a small piece of the iris may be excised. The only reason for doing this is to prevent blocking of the wound by incarcerated iris. Iridectomy is no essential part of Elliot's original operation. At the same time, a small iridectomy is no disadvantage to the patient, and as Elliot in his book (*loco citato* (15), p. 57) points out, it adds a decided element of safety to the case. In making the iridectomy, however, it is important to put no traction on the iris, or there is a danger of the iris becoming impacted in the trephine-hole. Another point is that the scissor points should be carried right down into the aperture when excising a bit of the iris.

Some good English operators now make a point of passing a spatula into the trephine hole, so as to free any peripheral adhesions between cornea and iris, in case the trephine has been applied too far back, and for a similar reason they invariably perform a small iridectomy, since in that case an opening must perforce be made either into the anterior or the posterior chamber.

Apropos this point, Dr. A. C. Norman (17) has pointed out that, by transillumination, a good idea can be got as to the extent of the peripheral adhesions between cornea and iris, and that this may be of service in determining how far forwards the trephine should be applied. When the transilluminator is pressed against the skin of the lower eyelid in a darkened room, the so-called "anterior scleral ring"—that is, the zone of scleral tissue that lies between the periphery of the cornea and the attachment of the iris—stands out as a brightly illuminated band, relatively wide in normal eyes, but narrower and narrower in proportion to the extent of the circumferential adhesions.

Although introduced so recently, numerous minor modifications have already been made in the *technique* of kerato-sclerectomy. Elliot, as already explained, dissects a triangular flap of the ocular conjunctiva from above the cornea. He insists (*loco citato* (15), p. 50) that a large flap implies subsequent easy drainage. It has been found as a matter of experience that in a certain proportion of cases the line of incision becomes adherent to the underlying sclera. This means, of course, that the larger the flap the more extensive the area left free for absorption of the aqueous humour escaped from the anterior chamber. Besides this, the fact that the flap is so fashioned as to remain in structural continuity with the ocular conjunctiva on each side of the cornea means that even if adhesions take place the aqueous can still find a means of reaching the subconjunctival spaces external to the line of incision.

When the conjunctival flap is made in accordance with Elliot's directions it lies during the subsequent course of the operation over the cornea, and thereby conceals from view what goes on in the anterior chamber. Again, owing to the close attachment of the mucous membrane to the cornea, there is a risk of button-holing the delicate flap of tissue. Dr. L. Webster Fox (18), of Philadelphia, overcomes these drawbacks by fashioning a quadrilateral flap, which is left attached by its base to the ocular conjunctiva of the upper-inner segment of the eyeball. During application of the trephine this flap lies well out of the way, and when the operation is finished, the hole in the corneo-sclera is covered by suturing the flap to the ocular conjunctiva on the outer side of the cornea. Dr. Roman v. Mende (19), of Mitau, also covers the aperture made by the trephine by a flap of conjunctiva dissected from the upper-outer quadrant, and held in place by a couple of sutures. Elliot dissects the conjunctival flap by means of a Bowman's needle, but Mr. B. T. Lang (20) for this purpose employs a modified Desmarres' knife.

Various instruments are used for making the hole in the corneo-sclera. A Bowman's trephine, as modified by myself (21), enjoys much popularity; and the same instrument, as still further modified by Colonel Elliot (22), is rapidly coming into favour (Arnold and Sons, London, E.C.). Trephines have also been devised by Mr. E. E. Maddox (23) and Mr. B. T. Lang (20) respectively. A few surgeons employ v. Hippel's clockwork trephine, often slightly modified to suit individual tastes (A. N. Walker, L. Webster Fox). Elliot (*loco citato* (15), p. 72) sees a danger in the extremely clean hole made by the v. Hippel instrument.

At an early stage in the history of kerato-sclerectomy, Dr. F. H. Verhoeff (24) devised what he called a "sclerostome," an instrument that combines the action of a punch and a trephine. It consists of an inner rod, armed at one end with a flattened button, and an outer tube, provided with a sharp cutting edge, like a trephine. The former fits closely into the latter. The button end of the rod is passed into the anterior chamber through a slit 2.5 mm. to 3 mm. in length, made with a keratome parallel with, and at about 0.5 mm. from, the limbus. The button is carried to one angle of the incision, and then the cutting end of the tube is screwed down upon the button. In this way the disc of sclera between the two parts of the "sclerostome" is cut cleanly out.

An ingenious and beautifully made sclerectome has been advised by Mr. Percy C. Bardsley (25), of London. It consists of a keratome and a punch combined. After a conjunctival flap has been resected in the usual way, the blade of the keratome is passed through the sclera into the anterior chamber, and pushed on until a piece of the sclera in front of the incision falls under the punch. The punch is actuated by a movement of the finger, and a circular disc of sclera is cut. The exsected morsel is withdrawn with the blade of the keratome, and it is claimed to be impossible to lose the bit of sclera in the anterior chamber when using Bardsley's instrument. The sclerectome is made by Down Bros., London, S.E.

Dr. G. Young (26), of New York, advocates the making of two trephine holes instead of one, as is commonly practised. Apparently, he avoids opening the anterior chamber, inasmuch as he operates at some distance from the limbus. Elliot (*loco citato*, p. 68) condemns the modification in no uncertain words, and speaks of the operation as "a violation of the first principles on which successful trephining should be founded."

In trephining the corneo-sclera, especially with instruments of small diameter, there is always some risk that the scleral disc may fall into the anterior chamber. According to Elliot (*loco citato* (15), p. 79), this accident, which occurs in about 1.6 per cent. of the cases, results from undue force at the conclusion of the trephining. Anything like heavy pressure must be carefully avoided, then, during the final steps of the trephining. *Prima facie*, there appears to be no reason why an aseptic bit of corneo-sclera should cause inflammatory reaction. Elliot himself attaches little importance to the occurrence, even supposing it proves impossible to remove the morsel by a gentle stream of fluid from McKeown's irrigator or by means of fine forceps. He mentions four cases where the incident occurred, but was followed by no unpleasant sequel. For my own part (27), I have described a case of my own where intense irido-cyclitis and loss of the eye followed the leaving of the disc in the anterior chamber, although I am now by no means convinced in my own mind that the two things were connected as cause and result. But the danger, real or assumed, has led Dr. G. Young (28), of New York, to devise a special trephine and a particular way of dealing with the sclera. His trephine may be described as a hollow cylinder, provided with a nut near the cutting end, and at the other end with a nut, so that the instrument may be grasped securely. After resection of the conjunctival flap, a suture is passed through the episcleral tissue covering the bit of sclera to be removed. The two ends of the retaining suture are twisted together, and passed through the hollow trephine from the cutting end outwards. By the aid of the thread, the eyeball is steadied, the sclera is fixed against the cutting end of the trephine, and, last but not least, the disc of sclera is prevented from escaping into the anterior chamber.

If I have dwelt at considerable length upon Elliot's operation and its modifications it is because, in my experience, it is quite the most satisfactory of the more modern operations for chronic glaucoma. Speaking for myself, I feel convinced that it has a great future. It is tolerably simple to perform; it entails little risk; and in many cases it succeeds in putting an end to the glaucomatous process. So far as one can yet judge, its results are permanent, and I have never yet known it to fail in reducing intra-ocular tension.

3. *Heine's Cyclo-Dialysis.*—This operation was described by Heine (29), of Breslau, in the year 1905. It is performed in the following way:—A flap of conjunctiva is first raised by scissors, and then by means of a straight keratome, after any episcleral tissue has been scraped away, an equatorial incision is made in the sclera at a distance of from 5 mm. to 8 mm. from the upper edge of the cornea. The wound has a length of about 2 mm. As soon as the uvea comes into view, a narrow spatula is passed into the incision, and passed carefully between the sclera and the uveal tract through the ligamentum pectinatum until its point is recognised in the angle of the anterior chamber. The aperture in the ligamentum pectinatum is next enlarged by slight cautious side-to-side movements of the spatula. The conjunctival flap is replaced, and if thought desirable, sutured. The underlying idea of the operation, of course, is to drain the aqueous fluid away from the anterior chamber into the suprachoroidal lymph space, and in so doing, to cause detachment of the choroid. But experience has shown that detachment of the choroid does not make its appearance even when the operation has been permanently successful in lowering intra-ocular tension. It is now thought that the success attending the operation is brought about by undermining the occluded angle of the anterior chamber.

With respect to the results attained by Heine's operation, Dr. Josef Meller (9), of Vienna, states that tension is lowered permanently in about 20 per cent. of the cases, that it is lowered temporarily in about 40 per cent., and that it is not affected either permanently or temporarily, in about 40 per cent. (*loco citato*, p. 217).

4. *The Heine-Fergus operation.*—Dr. Freeland Fergus of Glasgow (29a) reflects a flap of conjunctiva, removes a disc of sclera with the trephine, and passes the point of an iris repositor from the scleral aperture through the ligamentum pectinatum into the anterior chamber (*British Medical Journal*, October 2nd, 1909) and *The Ophthalmoscope*, February, 1910) He combines, in fact, a trephining operation with a cyclo-dialysis.

As a matter of some little historical interest, it should be noted that Fergus adopted the trephining operation before Elliot, and the last-named has very handsomely disclaimed any priority in the matter (14). Indeed, in the employment of the trephine in glaucoma, both were anticipated by Dr. Argyll Robertson (30), to say nothing of Blanco (1903) and Frohlich (1904). At the same time the operations advocated by Fergus and Elliot respectively differ so much that the sole point they can be said to have in common lies in the use of the trephine. In a sense both are obviously variants of Lagrange's perforating anterior sclerectomy, as vigorously maintained by Lagrange himself (31).

5. *Bettremieux's Simple Anterior Sclerectomy, non-perforating.*—The sclera having been exposed in the neighbourhood of the limbus by the reflection of a conjunctival flap, the outer layers of the sclera are pierced tangentially to the upper edge of the cornea by a needle slightly curved at its end. The scleral layers thus transfixed are then removed with a thin and narrow Graefe knife. In this way Bettremieux shaves away a piece of sclera measuring 1½ mm. in width by 2 mm. to 3 mm. in length. It has a thickness of about ½ mm.

The good results of the operation were first explained by the inventor (32) on the theory of the production of a true filtering cicatrix, or "filtering zone," as he preferred to call it. But he now maintains (33) that they are due to an anastomosis between the deep scleral vessels and the conjunctival and subconjunctival vascular plexus.

6. *The Thread Operation.*—By a singular coincidence, Mayou (34), of London, and Zorab (35), of Southampton, published at about the same time details of an operation for chronic glaucoma, the object of which was permanently to drain the anterior chamber by means of a silk seton (*The Ophthalmoscope*, May, 1912). But in the principle involved both had been forestalled by the late Mr. George E. Walker (11), of Liverpool. The immediate incentive appears to have been furnished by Mr. W. Sampson Handley's observations upon the drainage of cases of lymphatic and venous obstruction by means of silk threads. The operation upon the eye may be described as follows:—A flap of conjunctiva is reflected from above the cornea, and dissected up to the limbus. A short incision, 3 mm. in length and situated 2 mm. from the corneal margin, is made through the denuded sclera into the anterior chamber. For this purpose Mayou employs a short Graefe knife and Zorab a keratome. A piece of sterile silk suture is tucked into the incision, and thrust by means of a spatula into the chamber. Zorab uses a loop of thread, and Mayou a piece of the same material provided with a knot at its end. Finally, the conjunctival flap is replaced, and, if necessary, one or two sutures are inserted.

7. *Herbert's Operations.*—H. Herbert has tried to realise a filtering cicatrix in many ways (36), and for a time his so-called "Wedge isolation operation" appeared to represent the apogee of his numerous experiments carried out, for the most part, upon natives of India. The method he now seems definitely to have adopted (37) is that known as the "Small Flap Operation." Details follow:—Although the operation may be done with a very narrow Graefe knife, Herbert now usually employs a keratome and a modified Taylor's cataract knife or a Lang's synechia knife for the purpose. Prior to operation, the pupil is contracted as much as possible by physostigmine. The point of the keratome is placed upon the surface of the eyeball 4 mm. or more away from the cornea, and the conjunctiva is displaced towards the cornea with the instrument. The blade is passed into the anterior chamber immediately in front of the iris. In the next step, the modified cataract or synechia knife is introduced on the flat well into the anterior chamber. Its cutting edge is turned forward at one end of the primary incision, and by slow and sawing movements a small cut is made at right angles to the primary incision. The process is then repeated at the other end of the primary incision. The effect of these three incisions is to cut, as it were, a hinged flap, a trap-door, as it were, in the sclera, which, when it heals, will entail a permanent filtering cicatrix.

Only the other day (38) (*Proceedings of the Royal Society of Medicine, Section of Ophthalmology*, December, 1912, p. 29) Herbert spoke of yet another modification in the "small flap operation." By using so-called "twin-scissors," he made, instead of a single flap, three very small flaps of sclera. The underlying idea was that the lateral flaps interposed a barrier to the penetration of new blood-vessels into the central flap, and in that way prevented the latter from healing soundly into place, and thereby interfering with the filtration which it was its object to secure. This may be spoken of as the "Triple flap operation."

8. *Holth's Operation.*—The object of this operation, called also "*Iridencleisis antiglaucomatosa*," (39) is to establish a subconjunctival cystoid cicatrix. It requires many special instruments; its *technique* is difficult to describe; and, worse than all, it aims at deliberately entangling iris in the operative wound, a thing that for my own part I cannot consider as good surgery. For these various reasons its consideration need occupy us no further in this place.

(*c*) Palliative Treatment.

In cases of chronic glaucoma some surgeons still try to keep the process in check by the long-continued employment of myotics, or agents which contract the pupil, such as physostigmine (eserine) or pilocarpine. The latter is a milder agent than the former, which in susceptible persons is liable to produce twitching of the eyelids, spasm of the ciliary muscle, headache, and even nausea and vomiting. Pilocarpine is usually prescribed as a 1 per cent. or 2 per cent. aqueous solution of the hydrochloride or nitrate salt, and one drop of the liquid is applied to the eyes two or three times a day. An oily solution may also be used with advantage. Physostigmine may be employed as the sulphate or salicylate, 0.25 per cent. to 1 per cent., being instilled into the eye night and morning. A still better plan is to use Riedel's "Physostöl"—i.e., a solution of the remedy in oil. None of the agents acts upon glaucoma unless it succeeds in contracting the pupil and in keeping it contracted. A surgeon should therefore certify himself as to this all important point.

Palliative treatment, in my opinion, should yield to surgical measures the moment it is clear that the disease is advancing, as shown by the sight and, above all, by the condition of the visual field and the readings of the tonometer. Delay is only too likely to be disastrous to everybody concerned. In our present state of knowledge, it is very questionable whether the treatment of chronic glaucoma should be persisted in to the exclusion of surgical measures. Myotics never succeed in curing the malady.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Frederick S. Palmer, M.D., F.R.C.P.Lond., Physician to the West End Hospital for Diseases of the Nervous System, President of the West London Medico-Chirurgical Society. Subject: "Reflexes and their Significance."*

ORIGINAL PAPERS.

MY DUODENAL ULCER.

By XAVIER COMBES, M.D.,

Of the Faculty of Medicine of Paris.

[Specially Reported for this Journal.]

The history of my attack answers so exactly to the now classical description of duodenal ulcer that to relate it constitutes a complete clinical lecture on the subject.

I am æt. 43, and a medical practitioner. My father succumbed to angina pectoris at 59, and my mother to cardio-vascular troubles at 65, but she had long suffered from gastric ulcer. Personally I enjoyed good health until æt. 33 (1902) when I began to suffer from dyspepsia. Every day at about 10 a.m., I experienced acute pain in the right side of the epigastrium. The painful area could be covered by a five shilling piece. This supportable pain lasted about three-quarters of an hour, when it subsided, only, however, to recur on the morrow. This state lasted a month, and as I attributed it to hyper-acidity I discarded tobacco and irritating articles of food. In spite of this, digestion became more and more laboured for weeks and months at a time, and this went on for four or five years. Ascribing the symptoms as I did to acidity, I did not pay much attention to them.

In 1907, after a period of worry, my appetite suddenly failed and then, without any period of transition, I was seized with an overpowering sensation of hunger, associated with a distressing feeling in the stomach. The pain from which I now began to suffer came on twice a day, at 10 a.m. and at 4 p.m., and lasted until the next meal with intervals of improvement and exasperation. The pain was relieved by taking food of any kind, a tumbler of water calmed it for ten minutes, a cup of milk for half-an-hour, a piece of bread and a tablet of chocolate enabled me to await the following meal without much discomfort. Anything that distracted my attention momentarily relieved the pain. It often happened that the epigastric pain left me on entering a patient's house only to return as I went down stairs. Sometimes, however, the contrary happened, and if the consultation was prolonged the pain came back, manifesting itself by pallor of the face and drawn features, leading patients to remark, "Doctor, you seem to be in pain."

Some months later, after dining out, I had an attack of hæmatemesis. I remained in bed for twenty-four hours, and took nothing but milk for several days. I resumed my occupations on the morrow. The attacks became more frequent, and I consulted a fellow-practitioner, who diagnosed gastric ulcer. Thereupon I began to pay more attention to diet, refusing all heavy and stimulating articles of food.

It is not without interest to note that there were periods of quiescence coinciding with hot weather, but in stormy and rainy weather the pain returned worse than ever. I became very sensitive to variations of barometric pressure and also of temperature. When winter came the attacks increased in frequency and severity. At present it was not twice a day that I felt the pain, but thrice daily. The day pain was now complicated by nocturnal exacerbations. Towards midnight I used to be woke up by horribly acute pain, always on the right side and rather above the umbilicus, under the floating ribs. The pain occasionally radiated to the back. I wriggled into all sorts of positions in my endeavour to assuage the pain, but the one which afforded me most relief was flexion of the thighs on the abdomen tight enough to press on the painful area. Every night on going to bed I took care to place on my night-table a dry biscuit or a stick of chocolate, which I took as soon as the pain came on. This used to afford me temporary relief.

The attacks came on during the day at the same times. They set in with a flow of saliva into the mouth, this had a sweetish taste followed by a burning sensation and accompanied by acid regurgitations. Now and then I suffered from attacks of nausea and vomiting of food or watery fluid, and this was often followed by some relief. The teeth, especially the incisors, felt to me as if elongated, and on grinding them it felt as if I were crushing sand.

I was taking big doses of bicarbonate of soda which gave me instant relief, in fact just as soon as I had brought up a little wind. Unfortunately the relief was only ephemeral, the pain returning in about twenty minutes. When the attack came on in the street I used to run into a milk shop because a bowl of milk always put a stop to the pain.

In 1909 I tried electrotherapy. The continuous current seemed to aggravate rather than relieve, and I soon discontinued the treatment. I then placed myself on a diet composed exclusively of alimentary pastes, vegetable purées and stewed fruit. I took large quantities of bismuth, five drachms at a time, in water, of a morning. After a week of this treatment the attacks suddenly ceased. Unfortunately I was unable to keep to this diet, for several reasons. It gave rise to terrible constipation and I began to lose flesh rapidly, upwards of two pounds a week, and I felt very, very weak.

At this juncture I had melæna. Summer was coming on, and for several months the pain became less troublesome; in fact, I thought I was cured, but mere emotion, the least irregularity of diet, a fall of temperature, or a storm would precipitate a fresh attack. Then winter arrived and with it my suffering was aggravated. I managed, however, to get rid of the ten o'cock attack by substituting a bismuth paste repast for my breakfast. The same treatment, however, was not successful in relieving the afternoon pain. Thus another winter passed.

One day in May, 1910, I suddenly felt very unwell. There was a buzzing in my ears and I felt dazzled, my legs gave way under me and soon after there was copious melæna which lasted three days. I remained in bed twenty-four hours, sucked ice and then resumed my work. Solid food assuaged my pain, but I avoided eating because I noticed that the relief afforded by the ingestion of food was followed by a recrudescence of the pain soon after. Moreover, anything like a full meal gave rise to a distressing feeling of distension with oppression, yawning and belching so that the period of relief preceding the attack was the shorter the more copious the meal.

In 1911 I had occasion to pay a visit to my good friend, Dr. Larmandieu, of Rollot. I told him my tale of woe, and he at once exclaimed that it was not gastric ulcer I was suffering from but duodenal ulcer. I asked him how and on what grounds he had jumped to that conclusion, and he replied that the symptoms I had related were absolutely typical. He said, "Why you have the painful hunger and the pain coming on three or four hours after a meal, which pain is relieved by food. It is worst at the junction of the epigastrium and the right hypochondrium, you have had symptoms of hyperacidity and have had attacks of melæna. All these accidents have been presented, come on in attacks lasting several weeks or months, and are influenced by atmospheric conditions. Why, my friend, you are a splendid example of typical duodenal ulcer." "So much for the diagnosis," I said, "but what as to treatment?" "There is nothing for it but an operation," he replied, "but the statistics are reassuring: barely one death in a hundred." I left him somewhat reassured; in fact, if it had concerned a patient I feel that I should not have felt in the least anxious, but as myself was in question I had a sneaking idea that the ulcer might have degenerated into cancer. Still, I did not hesitate, and decided right away to undergo the operation as soon as the season came for a good many of my patients to go into the country.

A month after (August, 1911) came another attack of melæna, the worst I had had. I was seized in the street at 10 p.m. with stomach ache and an urgent call to go to the rear. I hastened into a café and expelled an enormous tarry mass. Thereupon I betook myself home. On my doorstep I was seized with noises in the ears and had but just time to open the door and throw myself on the sofa. This attack lasted three days, and it left me exsanguine and utterly prostrate. Nevertheless I went on working for a few months more, leading a most distressing existence, not only on account of the pain but also on account of my apprehensions of a further hæmorrhage. This occurred in April, 1912, and now I made up my mind not to wait any longer.

I called for my friend, Larmandieu, and got him to go with me to Amiens to see Dr. Panchet, who was operating at the St. Vincent-de-Paul Hospital. I lay down on a bed and he palpated the abdomen and asked a few questions before saying: "You have a duodenal ulcer; we must perform gastro-enterostomy and exclude the pylorus. The operation is not very dangerous, but I should like you to come into my home for the purpose of a radiographic examination and a test meal." I went into his home, but it was not thought necessary for me to undergo any further exploration, and it was decided that I should be operated on on the morrow after washing out of the stomach and intestine.

Of course, I can say nothing as to the operation, but I was informed afterwards that on laparotomy being performed I proved to have an absolutely typical duodenal ulcer. The vein which serves to mark the junction of the pylorus and duodenum was well marked and the ulcer was on the upper part of the first portion of the duodenum, an inch from the pylorus. It was the size of a sixpenny piece. The greater part of the upper portion of the duodenum was adherent to the gallbladder and liver. The procedure adopted was the posterior vertical operation with a short loop (vertical suspension) followed by exclusion of the pylorus.

One word about the anæsthetic. As I was suffering from a cold it was thought better to administer chloroform, but it seems I took it badly, so recourse was had to ether. But for this the sequel would have been quite uneventful. As it was I developed a sharp attack of bronchitis and the paroxysms of cough set up a good deal of pain in the suture. On the seventh day, however, things were going on so well that I got up and began to take light food and by the tenth day I began to walk about. On the twelfth day the stitches were taken out and on the fifteenth day I was able to be present at several operations. Since then my health has returned to normal.

HÆMATEMESIS AS A CAUSE OF DEATH.

By DONALD E. CORE, M.D., M.R.C.P.,

Honorary Physician to the Ancoats Hospital, Manchester.

HÆMATEMESIS is not a common cause of death, and this considering the number of diseases in which it is encountered, and the extreme prevalence of some of these diseases, is worthy of notice. Thus, for example, vomiting of blood is one of the cardinal symptoms of gastric ulcer and of cirrhosis of the liver; diseases admittedly of frequent occurrence. Yet in spite of this, it is quite uncommon for either of these diseases to terminate fatally through hæmatemesis. (*a*)

During my term of office as resident medical officer at the Manchester Royal Infirmary, a period of two years, there were but twelve fatal cases of hæmatemesis:

Gastric ulcer	6
Hepatic cirrhosis	3
Carcinoma stomach	1
Duodenal ulcer	1
Aneurysm of aorta	1

In the last case the vessel ruptured into the œsophagus, with profuse hæmatemesis.

It is, however, not so much from a statistical point of view that I wish to approach these cases, as from the standpoint of the mode of death brought about by the bleeding, and from this standpoint, hæmatemesis falls into three groups:

A. In which death is the immediate result of the bleeding;

B. In which death is due to asthenia, the result of many repeated hæmorrhages;

C. In which death is due to acute cerebral anæmia, supervening several hours after the last bleeding, and causing sudden collapse.

I propose considering these three groups in detail and in the light of illustrative cases.

GROUP A.—*Cases in which death is the immediate result of hæmatemesis.*

This comprises six out of the twelve cases. Of these six, five were males and one female. Average age, 41. The history is generally one of definite indigestion which may or may not be typical of gastric or duodenal ulceration, with or without preceding bleeding. The patients in this group, as a rule, do not die in the first bleeding, but this bleeding is followed by one or two more attacks, in which death occurs. The bleeding is, as might be expected, profuse in these attacks, and the patient is much prostrated.

A. B., female, æt. 42. Admitted into the Manchester Royal Infirmary complaining of very indefinite symptoms of indigestion; vague diffuse abdominal pain without any definite localisation, no lateral spinal pain, and general abdominal tenderness. The pain is sometimes made better and sometimes increased by food, and when it does come after food, there is no constant interval of time between ingestion and the onset of the pain. Nausea is a prominent symptom, but there has been little or no vomiting. No history of hæmatemesis. The stomach on examination is moderately dilated, and the gastric content shows the presence of free acid. The patient was considered a case of perigastric adhesions with gastric dilatation. Examination with the X-rays did not show anything suggestive of active ulceration or hour-glass contraction. The chief complaint was persistent and continuous abdominal pain, which did not improve under treatment.

After the patient had been in bed for some weeks, she quite suddenly vomited a large quantity of bright blood. Shortly afterwards she vomited a smaller quantity of rather dark blood, and became in a markedly exhausted condition.

Two or three hours later she collapsed suddenly and brought up a small quantity of bright blood. She died immediately after.

Post mortem, a large area of ulceration was found and in this area was the eroded artery that had given rise to the bleeding. The ulcer was adherent to the surrounding organs by adhesions which were recent and old. The stomach showed hour-glass contraction. The stomach and intestines contained a large quantity of effused blood.

GROUP B.—*Cases in which repeated hæmatemeses produce an asthenic condition terminating fatally.*

This accounts for five out of the twelve cases; two males and 3 females; the average age being 31 3/5 years.

The history is generally a very characteristic one of gastric ulceration, with in most cases preceding attacks of hæmatemesis. The patient, after treatment has begun, for a time does well, and then begins to complain of severe epigastric pain. Throughout the whole subsequent course of the case this is the chief complaint of the patient—severe, persistent and utterly intractable pain, and this appears to be quite independent of the food taken. The bleeding first appears shortly after the retrogression begins; the first attack is generally a severe one, and leaves the patient profoundly prostrated and blanched. It is in these cases that one sees the anæmia so characteristic of gastric hæmorrhage developed to its extreme. A second bleeding follows shortly after the first, and the course of the case is one of intense abdominal pain and a succession of hæmorrhages, varying in severity. There is generally little or no attempt at any blood regeneration. The patient becomes distended, and shows signs of local peritonitis in the epigastric region. He gradually assumes the typhoid state and dies in a state of complete asthenia. These cases are very similar to certain cases of pulmonary tuberculosis, where death is associated with repeated attacks of hæmoptysis and corresponding asthenia.

The temperature in these cases of hæmatemesis is generally raised at the onset of the epigastric pain, but subsequently becomes subnormal after the attacks of bleeding have set in. Any attempt on the part of the organism to emerge from the asthenic condition as manifested by the temperature beginning to rise, is invariably followed by hæmorrhage and subsequent relapse to the typhoid state.

Towards the end of the case the blood vomited

(*a*) *Medical Chronicle*, Manchester, March, 1913.

is black and grumous instead of being red as at the onset of the fatal symptoms With the abdominal pain is marked tympanites and intense tenderness.

This mode of death is common in the so-called return cases after a gastro-enterostomy has been performed without the relief of symptoms.

There is in addition a group of cases in which this course of events may almost be predicted; such patients are usually males, and between 30 and 40 years old. They are slightly built, and as has been said, they give a characteristic history of gastric ulceration. The most significant feature of these cases is the curious and most marked floridness of the cutaneous and mucous surfaces. The pain is so persistent and so savagely intense; the bleeding so utterly unaffected by treatment, and the final asthenia so profound, that such cases are perhaps the most pitiable that can be encountered.

Post mortem, the appearances are those of extensive ulceration of the stomach with one or several orifices of ruptured vessels visible in the midst. There is always marked and recent plastic peritonitis about the stomach in the immediate neighbourhood of the ulcerated area.

The following is an illustrative case of this group.

A. W., æt. 25, labourer. The patient gives an 18 months' history of illness, consisting of localised epigastric pain coming on almost directly after food, and passing through to the back; vomiting which eases the pain, and hæmatemesis. He has had four attacks of bleeding altogether. The symptoms tend to improve for a time and then relapse. The present attack has lasted seven weeks, and so far there has been no bleeding.

The health generally up to the onset of the present illness has been good, and there is nothing of any importance in the past history.

The patient is a small man, wasted, feeble, and with a flushed facies and bright red lips Examination revealed definite finger-tip epigastric tenderness and a dilated stomach. There was left lateral spinal tenderness. The heart was small. The lungs were normal.

The patient made good progress for the first three weeks or so of treatment, and then complained of a sensation of nausea and epigastric pain. The abdominal tenderness increased in extent, and there was a few days later a brisk hæmorrhage from the stomach, which was repeated frequently during the following week. The abdomen became distended and the tenderness and pain increased. The patient assumed the typhoid state and the blood vomited became black-brown in colour and of daily occurrence.

He died some three weeks or so after the occurrence of the first hæmorrhage.

Post mortem, a large ulcer was found in the stomach implicating several vessels. These were eroded and gaping in the thin ulcerated area. The stomach external to the area of ulceration showed marked peritonitis.

Group C.—*Cases in which death occurs a few hours after a profuse loss of blood from the stomach.*

This group most resembles Group A in that death is more directly the result of the anæmia produced by the bleeding but it differs from the cases of that group in that death does not occur immediately as a result but is delayed for a few hours and then appears to be due to sudden collapse on the part of the patient. A case which very well bears this out is one which I saw some months ago where a man æt. 29 who gave no history of previous indigestion but who had been under treatment two years before for sudden hæmatemesis vomited a large quantity of blood while at work. He was brought into the hospital vomiting blood on the way and when he was seen he was in a state of extreme anæmia and collapse with sighing breathing and an imperceptible pulse. He was transfused and rallied but shortly afterwards vomited more bright blood. Transfusion was again performed; he was given a hypodermic injection of morphia and improved greatly. Ten hours later he quite suddenly collapsed again, became restless and manifested all the signs of a severe internal hæmorrhage. There was, however, no external evidence of bleeding. He died a few minutes after the onset of these symptoms.

Post mortem, he was found to be suffering from hepatic gummata with inter-cellular cirrhosis. There was no apparent breach of the gastric mucosa and no varicosities of the lower œsophageal veins were to be seen. The stomach and upper intestine contained no blood at all but the lower part of the small intestine and the large bowel were full of black blood. In other words, there were no signs of any fresh bleeding such as had been expected from the terminal symptoms. It is probable that these terminal symptoms were due to some sudden movement on the part of the patient causing acute cerebral anæmia. This case presented many points of interest and I hope to record it fully in the near future; I quote it now from the point of view of the delay in onset of death which occurred without any further hæmorrhage.

Two out of the 12 cases fall into this group, both being males. The average age is 33.

To summarise these groups I should say that death from hæmatemesis is not common in ulcerated states of the stomach or in hepatic cirrhosis; that when it does occur it is as frequently due to profound asthenia resulting from repeated bleedings as from sudden heart failure due to one or two profuse hæmorrhages.

In a small proportion of cases of fatal hæmatemesis death is the result of acute cerebral anæmia supervening at an interval of several hours after the last bleeding.

THE
INTRAVENOUS ADMINISTRATION OF NEO-SALVARSAN IN SYPHILIS.

By J. A. NIXON, M.B.Cantab., F.R.C.P.,

Physician and Physician-in-Charge of Skin Department, Bristol Royal Infirmary.

Neo-salvarsan is a new derivative of salvarsan, obtained by Professor Ehrlich by the action of formaldehyde-sulphoxylate upon salvarsan (dioxydiamidoarsenobenzol). The resultant compound contains as its active constituent dioxydiamidoarsenobenzol - monomethane - sulphinate of sodium and bears the number "914" in Ehrlich's series. (*a*)

The first great advantage of neo-salvarsan over salvarsan is the ease with which it dissolves in water. Unfortunately, like many other organic arsenical compounds, it is unstable, and readily

---

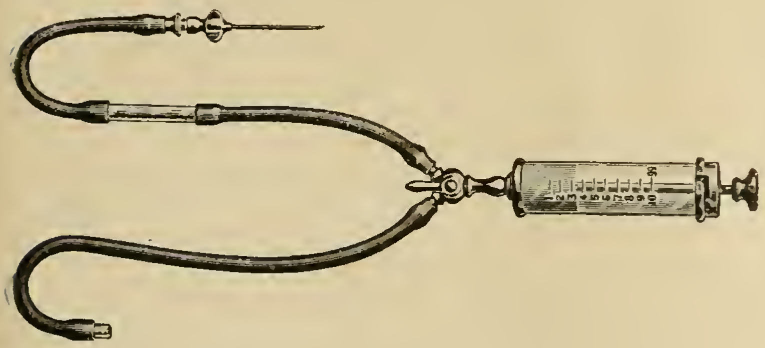
(*a*) *Bristol Medico-Chirurgical Journal*, March, 1913.

oxidises, giving rise to products which are exceedingly toxic.

My experience with this drug is short, but I am convinced that it possesses many advantages over the original salvarsan in the treatment of syphilis. The *technique* of administration is comparatively simple, but it demands close attention to detail.

Neo-salvarsan may be given intra-muscularly or intravenously; but the later is the method with which I propose to deal.

McDonagh's method of using a syringe for intravenous administration is excellent, and with slight modifications Messrs. Ferris and Co. have made for me a compact injection apparatus which fits on to an ordinary 20 c.c. Ehrlich-Hata "Record" Syringe. To the nozzle of the syringe a three-way stop-cock is screwed on, the needle of the syringe is connected with one branch of the stop-cock by a piece of rubber tubing about eight inches long, into which a "window" of glass tube is inserted two inches from the needle. To the third branch of the stop-cock a piece of rubber tubing twelve inches long is attached, through which the syringe can be filled from the solution of neo-salvarsan. A turn of the tap enables the contents of the syringe to be injected through the needle into the vein.



The preparation of the solution of neo-salvarsan is carried out as follows: Into a sterilised beaker is poured, with aseptic precautions, a sufficient quantity of the twice-distilled sterilised water to allow 25 c.c. of water for every 0.1 gramme of neo-salvarsan. The twice-distilled water is absolutely essential to avoid a febrile reaction after the injection; and it is advisable to sterilise in an autoclave the flask of water after re-distillation. The re-distillation and autoclaving should be done not longer than the day before injection. The phial of neo-salvarsan is then opened. The neck of the phial is rendered aseptic by wiping with a cotton-wool swab soaked in absolute alcohol, and filed off with a small file sterilised in the flame of a spirit lamp. Heat must not be applied to the phial itself. The contents of the phial, consisting of a finely-divided yellow powder, is shaken on to the surface of the water, and allowed to dissolve spontaneously without shaking or stirring. If the solution is not perfectly clear at the end of ten minutes, it should not be stirred or filtered; more distilled water should be added. If the water was perfectly clear of all solid particles, there will be no need of filtering: Neo-salvarsan will dissolve completely, provided sufficient water is added. A turbid solution indicates an insufficiency of water.

A second beaker should be prepared, containing sterilised normal saline solution, made from twice-distilled water. A vein at the bend of the elbow is meanwhile made to distend by placing a rubber tourniquet, secured by artery forceps, round the upper arm, taking care that the radial pulse is not obliterated.

The skin over a wide area is disinfected by swabbing once with Liquor Iodi Fortis (B.P.). The syringe and needle are completely filled with normal saline solution through the spare end of rubber-tubing, and all air bubbles carefully got rid of. The needle is introduced into a conveniently distended vein. It is better to ascertain the whereabouts of the needle's point by gently injecting a little saline solution rather than by attempting to suck up blood into the syringe. If the point is not in the vein, subcutaneous infiltration will immediately be visible as a slight swelling. Provided no such swelling appears, a few c.c. of saline solution should be injected into the vein, and the plunger withdrawn until pure blood is seen in the glass window-tube. This must be immediately re-injected, or clotting may occur in the needle.

Having made sure that the needle is properly introduced into the lumen of the vein, the needle can be kept in position by tying a piece of gauze round the tubing just above the junction with the needle (if gauze is used instead of tape or a bandage a single knot suffices, and will not slip). The tourniquet is then relaxed; a most important preliminary, and one sometimes forgotten. By a turn of the stop-cock the saline solution is emptied out of the syringe, the spare end of tubing placed in the neo-salvarsan, and the syringe filled with neo-salvarsan solution. The stop-cock is turned over to the needle, and the solution injected into the vein. This alternate filling with the neo-salvarsan and injection into the vein is continued by appropriate reversing of the stop-cock until the whole of the solution is injected. A final syringeful of saline solution should be injected to wash through the whole of the neo-salvarsan into the vein, and avoid the possibility of infiltration of the subcutaneous tissues with neo-salvarsan on withdrawing the needle.

If the subcutaneous swelling appears during injection, either the needle has become dislodged or the vein has been transfixed. A little saline solution should be injected to dilute the neo-salvarsan in the tissues, and a fresh vein must be taken for the remainder of the injection. The pain of subcutaneous injection of neo-salvarsan is intense and must be avoided.

At the end of the injection a pad of sterilised gauze is bandaged over the spot, as bleeding sometimes takes place. Carried out in this way, the operation should be followed by no reaction and no rise of temperature. Patients prefer the actual injection to be performed as quickly as possible. Using 0.9 grammes of neo-salvarsan in 250 c.c. of water, I find the injection may be made in just over five minutes. The solution is injected at room-temperature about 55°—60° F. On a very cold day the flask of water may be warmed by standing in hot water prior to making the solution; but the solution must on no account be warmed after the neo-salvarsan has been added. The solution must be freshly prepared at the time of injection, and it must not be carried about or agitated. With these precautions the danger of toxic decomposition products being formed from the neo-salvarsan is averted.

Every instrument, towel, swab, &c., to be used at the operation is sterilised by boiling or superheated steam. Sterilised towels are clipped round the patient's arm, leaving only the iodine-painted area exposed. Sterilised towels are placed under the arm and over a sufficient surface of the table or bed on which the arm rests to ensure that the syringe and its various attachments may be safely laid down if necessary upon a sterilised surface.

I find it convenient to stand the two beakers of neo-salvarsan and saline solution in a double pickle jar stand, so that both may be carried about and handed to me simultaneously. Solid particles or air-bubbles might prove fatal if injected into the vein. Should an air bubble by chance appear at the glass window tube, it must be at once drawn back again into the syringe and allowed to float up to the top. The injection may then be continued. An air bubble of considerable size in the syringe does no harm if the syringe is held perpendicularly, and the plunger is not pushed home at each thrust so as to empty the syringe. Personally, I prefer to keep a fairly large air bubble at the top of the syringe, as small bubbles if they occur in the solution can be more easily dislodged from the sides of the syringe and made to incorporate themselves in the larger bubble, which I watch constantly.

The patients do not, as a rule, experience any unpleasant effects either during or after the injection. Some complain of a slight metallic taste at the end of the injection, but it is quite transitory. Occasionally a slight headache comes on two or three hours afterwards, and I find a cup of tea is the best remedy.

It is advisable to prepare the patients as if for an anæsthetic by administering an aperient on the previous night, and giving a very light breakfast on the morning of the injection. Ordinary meals may be taken after the injection. The patients should remain at rest, preferably in bed, for two hours; if at the end of that time no unpleasant symptoms have occurred, I allow them to get up, provided they remain quiet. The first injection requires greater caution than subsequent ones, so far as after-treatment is concerned. If the patients stand the first injection well I allow them to get up and go out and about within a few hours after subsequent injections.

The dosage I employ is 0.75 gramme (No. V.) for a first injection in a healthy man, with subsequent injections of 0.9 gramme (No. VI.), at intervals of three days (in practice two injections per week), until four or five injections have been given. The Wassermann reaction in an early case of syphilis is usually positive up to four injections; if it is negative a week after the fifth injection I do not repeat the injection unless a later test shows a positive reaction again. If after the fifth injection the reaction is not negative, I give a sixth or seventh injection, with intervals of a week, taking a Wassermann test a week after each injection, and being guided as to a repetition of the dose by its results. I discontinue mercury for at least a fortnight before the first Wassermann test is made, but afterwards combine the treatments. Before finally deciding that no further neo-salvarsan is necessary, I make a final Wassermann test, preceded by a fortnight without mercury.

Neo-salvarsan is apparently contra-indicated in alcoholic debilitated subjects, or in those suffering from cirrhosis of the liver. I make it a rule to examine the urine beforehand, ascertaining with particular care that the quantity secreted is normal, that the specific gravity is within healthy limit, and, above all, that the excretion of urea is sufficient.

A trace of albumen may depend upon the syphilitic infection, but the presence of casts or sugar should in the present state of our knowledge deter us from administering any of the arsenic compounds intravenously. In cases showing signs of any syphilitic involvement of the central nervous system, especially meningitis, spinal symptoms, psychoses, or optic neuritis, great caution should be exercised, and if neo-salvarsan is administered at all, the dosage should be very small at the outset.

Observing these precautions, neo-salvarsan offers a very valuable adjunct to the mercurial treatment of syphilis. The patient's infectivity is quickly minimised if not abolished, the visible signs of syphilis are speedily dispersed, *e.g.*, the chancre, roseola and condylomata may disappear after the second injection. The symptoms are alleviated, and the Wassermann reaction changed from positive to negative, whatever this may really mean.

Time alone can demonstrate whether more solid advantages accrue, but alleviation to this extent is a gain not lightly to be disregarded. At least, neo-salvarsan offers the advantages aforesaid, as well as marked benefits in later manifestations, particularly tertiary lesions of the skin and mucous membranes. Some cases of locomotor ataxy and late nervous disorders have been improved.

In addition to these considerations it may be observed that neo-salvarsan, if cautiously prepared and administered, shows little or no toxicity, that it is easily dissolved, requires no elaborate apparatus and is injected at room-temperature. While the use of re-distilled water has proved the "reaction" after intravenous injections to depend more upon some ill-understood quality of the water than upon the drug employed.

OPERATING THEATRES.

GREAT NORTHERN CENTRAL HOSPITAL.

Operation for Rhinophyma.—Mr. Arthur Edmunds operated on a man, æt. 50, who had had an enlargement of the nose for several years. For the last twelve months the disfigurement had been so pronounced that he was faced with the alternative of having something done for his condition or losing his employment. The nose was much enlarged and the tip hung down towards his mouth, forming a thick fleshy flap. Laterally there was great expansion, the sulci over the alæ nasi being quite obliterated. To those who came in contact with him in business his appearance suggested that of a heavy drinker, although, as a matter of fact, he was an extremely abstemious man. . The dilated vessels over the nose accentuated this false impression.

He was admitted to the ward for operation. This consisted merely in reshaping the organ with a sharp knife. The actual instrument employed was a skin-grafting knife provided with a fixed handle. The profile was first attended to, a thick strip of tissue being pared off, until the shape of the organ was satisfactory; care being taken to avoid going too deep and injuring the cartilages of the nose.

The sides were then pared away until the appearance from the front was approximately normal. When this had been done the nose was fairly well proportioned, but its sides were too flat and there was no sulcus over the alæ nasi. Accordingly two wedges of tissue were excised on each side so as to produce a more normal shape, and the wounds caused in this way sewn up.

There was a certain amount of bleeding during the operation, but this was never troublesome and soon stopped. The wound was then dressed with "protective," perforated with holes to allow of the escape of discharge, which was absorbed by a gauze dressing.

In these cases the hyperplasia is due to the increase in the size of the sebaceous glands; and hence, in shaving down the excrescences, the knife passes through the glands, leaving their bases in the wound. Although, therefore, the nose looks absolutely raw at the conclusion of the operation, there is no need for any skin-grafting, inasmuch as the organ is soon covered with epithelium which grows from the bases of the sebaceous glands scattered over the raw surface. In a few days the epithelial covering is completely regenerated from these numerous foci, and a thin, fairly natural skin is produced, much more resembling the normal integument than a scar. In this case the wound was completely healed in a fortnight, the incision where the wedges had been excised uniting readily, and the man's appearance was sufficiently benefited to enable him to mix with other people without exciting comment. He was allowed to resume his employment.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Section of Obstetrics and Gynæcology.

Meeting held Thursday, July 3rd, 1913.

The President, Dr. Amand Routh, in the Chair.

A short communication on a

calcified fibroma of the ovary obstructing labour

was read by Dr. H. S. Souttar, and the case was discussed by Dr. Herbert Spencer, Dr. Drummond Maxwell and Dr. Hubert Roberts.

Mr. Charles P. Childe (Portsmouth) read a paper on

suggestions for the technique and performance of wertheim's abdominal hysterectomy.

The author pointed out that the two conspicuous risks of the operation were shock and sepsis. Certain conditions specially favourable to the occurrence of infection should be recognised—(*a*) diminished resistance due to bad general health; (*b*) a certain amount of injury to the tissues of the abdominal wall due to retraction required during the operation; (*c*) the presence of a pelvic wound open to the external surface through the vagina; (*d*) the space of Retzius freely opened, offering favourable position for the accumulation of fluids. In some cases general infection from an ulcerating malignanat growth is present at the time of operation. Great care should be taken to avoid fouling of the wound surfaces when the vagina is divided. The author's practice was to remove all the soft parts of the growth with scissors and sharp spoon as the first stage of the operation. The raw surface was then freely cauterised, and the vagina carefully dried and painted with 2 per cent. iodine in spirit. Finally the vagina was closely packed with dry sterile gauze, the end of which was left hanging out of the vulva, to be withdrawn when the vagina was divided later on. Another important point was the manner of dealing with the pelvic wound. The author had entirely given up drainage with gauze as recommended by Wertheim, and he now never employed gauze except for hæmostasis. He laid great stress on securing complete hæmostasis, and on leaving as few ligatures as possible in the pelvic wound.

In the easiest cases the operation was severe and prolonged, and shock could best be controlled by shortening the operative procedures as much as possible. The longest part of the operation was dealing with the parametrium and the divided edges of the vagina. The author now employs only four ligatures (silk), one for each ovarian and one for each uterine artery. The round ligaments and parametria are crushed with strong forceps and the tissues divided with Paquelin's cautery. Bleeding from the vaginal walls could be avoided by applying a modified Wertheim's forceps to the part to be divided for a moment beforehand. In this way a dry pelvic wound could be secured, and the cautery would destroy cancer cells in the seared tissues. Finally, the peritoneum is sewn over without drainage, and the abdominal wound closed in layers. A ligature or two may be required when separating the bladder. A special crushing forceps designed by the author was shown.

The paper was discussed by Dr. Herbert Spencer, Mr. Douglas Drew, Dr. Russell Andrews, Mr. Vaughan Sawyer, Dr. Cuthbert Lockyer, and Dr. H. Taylor Young (Sydney, N.S.W.).

The President then delivered his valedictory address entitled "Observations on the Toxæmia of Pregnancy and on Eugenics from the Obstetrical Standpoint."

Votes of thanks were passed to the retiring President, to the retiring Vice-President, to the Chairman of the Pathology Committee, to the retiring Hon. Librarian, and the retiring Hon. Secretary, and the Section closed for the Session.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, July 12th, 1913.

At the Congress for Gynæcology, Hr. Mohr, Halle, spoke on the

Internal Secretion of the Salivary Glands and its Relation to the Genital Organs.

He said that hitherto nothing was known of any internal secretion of the salivary glands. Clinical experience, however, was distinctly in favour of such a secretion, that these glands played a part in the great system of endocrine glands, and that there was a special relation between them and the sexual organs. It was known that after ovariotomy swelling of the glands took place partly due to infection and in part to checking of secretion through insufficient nourishment. Disease of the genital organs was also known to take place in connection with mumps. The observations of the speaker were also very interesting in which he showed that in cases of syphilis simultaneous affections of the testicles and the glands in question had been noted. Observations made by him had appeared to make it more certain that such a connection existed, genital infantilism, hypofunction of the genital glands in Basedow's disease, in the status lymphaticus, in endogenous obesity of the thyreogener genital and hypophysar form. The speaker had observed a total of 17 cases of disturbance of the salivary glands in which the parotid, sublingual and other and in some instances the lachrymal took part. In some cases there was a good deal of enlargement of the glands, which led to considerable disfigurement of the face. As regarded the so-called Mikulicz disease, it was not an independent affection but one that was brought about by different pathological conditions. The condition was one either of primary anomaly or an acquired one, and in the latter case it was, perhaps, compensatory—a hyperplasia like that of swelling of the thyroid after removal of the ovaries or after the climacteric.

Hr. Albrecht, Munich, discussed the

Internal Secretion of the Mammary Gland.

On the basis of experiments performed by himself, the speaker came to the conclusion that extirpation of the mammæ in a young lamb had no appreciable influence on the development of the animal, the individual systems of glands, rut, gravidity, or labour. Strictly, the mammæ should not be considered as glands with internal secretion. After extended experience in the injection of mammary extract he found some inhibition of the ovarian function, and in the human subject suppression of the menses. It was questionable whether this was due to any specific action of the mammary extract. Various observations led to the assumption that it was possibly due to a toxic effect produced by other organs. These substances that did not come into the circulation physiologically were reabsorbed after free accumulation during lactation, and it was then that they exerted their inhibiting influence on the ovarian fuction.

Hr. Mosbacher, Frankfort a/M., read a paper on the subject of

THE THYROID AND PREGNANCY.

All the pregnant animals treated (thirty guinea-pigs and three cats) with only two exceptions aborted when fed with thyroid gland material. All the control animals fed with mutton suffered no interruption of their pregnancies. Thyreoglandol (Hoffman, La Roche and Co.) often acted as an excitor of uterine contractions. Of forty women to whom it was given by injection in different quantities, twelve of them had their labour pains increased and strengthened. In twelve cases in which the injections had no effect a combination of thyreoglandin and adrenaline was given, but in all without any effect. Seven of the cases showed brilliant results from the use of pituitrin.

Hrn. Lichtenstein, Leipsic, and R. Freund, Berlin, discussed the

TREATMENT OF ECLAMPSIA.

The former was an advocate for the "waiting or expectant" form of treatment. Of 94 cases treated by venesection and delivery the mortality was 5.3 per cent. The infant mortality was 37.3 per cent., for the viable infants 21.6 per cent. Seventy-four cases in uninterrupted series recovered. For sixteen months there was no death from puerperal convulsions. The necessity for active treatment was, therefore, not proven, but must be looked on as positively harmful, and should give place to the expectant form.

Hr. Freund, who took an opposite view, said that in the Leipsic Hospital between October, 1912, and April, 1913, 46 cases of eclampsia had been submitted to the expectant method of treatment (venesection and narcotics); four mothers died of convulsions, two recovered during gravidity. One bad case of eclampsia during pregnancy got very much worse at the sixth month, and anterior hysterotomy had to be performed to save her life, which it did. The infantile mortality had much increased under this treatment. It was 41.9 per cent., against 17 with early delivery. He also reported as regarded some other toxines (one toxicoderms, and two cases of hyperemesis). The first three skin cases recovered after injections of gravid serum, the following four after horse serum. For the last nine skin cases and those of hyperemesis, 200ccm. of Ringer's Solution were injected. All recovered except the last five skin cases, one of which proved quite refractory, the rest suffered four relapses, and three of them recovered spontaneously later on.

AUSTRIA.

Vienna, July 12th, 1913.

PATHOLOGY OF THE SPLEEN.—SPLENECTOMY: ITS INDICATIONS AND RESULTS.

AT the late meeting of the Gesellschaft für Innere Medizin und Kinderheilkund in Vienna, Dr. H. Eppinger made a communication on the pathology of the spleen. It was first pointed out that oscillations of the iodine standard of the blood fat, which had been freed from cholesterin and cholesterin-esters, had appeared both before and after splenectomy. The iodine standard reached the minimum after extirpation of the spleen, while it was at highest after toluylendiamin poisoning. Analogous researches had been made on human blood in the most varied conditions of disease. Here the iodine standard was very high in the hæmolytic processes—*e.g.*, in pernicious anæmia, hæmolytic icterus, hypertrophic liver cirrhosis, and in catarrhal jaundice. The determination of the quantity of urobilin in the alvine evacuations was also discussed. The normal amount *pro die* is 0.15 gr. Great variation is observable in pathological conditions; the largest amount met with was in hæmolytic jaundice, in which it amounted to 3.4 gr. Large quantities were also met with in pernicious anæmia, in some forms of icterus catarrhalis; also in many of those cases of cirrhosis which are accompanied by icterus. When the fact is recognised that urobilin is derived from the broken-up hæmatin, it can be utilised as a measure of the hæmolysis proceeding at the time.

Further indications may be derived from the parallel coures of the high iodine standard and the high urobilin values. Splenectomy is indicated in cases of hæmolytic icterus; thereupon the quantity of urobilin found in the fæces sinks to the normal quantity. As this fact proves the enormous influence which splenectomy has on the hæmolysis—the data being estimated by the urobilin values—so does the same operation appear to be indicated on therapeutic grounds, in other cases of increased hæmolysis. In accordance with this view, the spleen—although apparently not enlarged—was removed in two cases of uncomplicated pernicious anæmia. The result was actually brilliant: the number of erythrocytes rapidly increased till it reached the normal. The body-weight increased—up to 10 kg. The urobilin values sank to a subnormal level. The patients felt themslves perfectly well. Now two months have elapsed since the operations, so that there can be no doubt of the establishment of the cure, and the results are extremely encouraging. Mention was also made of the operative procedure in two cases of hypertrophic cirrhosis of the liver. The icterus rapidly disappeared, and improvement of the general condition set in. Within a comparatively short time ten patients, who showed indications of increased hæmolysis, had been subjected to the operation of splenectomy. Some of them had displayed the so-called Banti's symptom—complex. The result was always a conspicuous one. Histological examination of the spleen showed, in some of the cases (pernicious anæmia, hæmolytic icterus), intense hyperæmia in the neighbourhood of the sinus; in others, fibro-adenic (Banti's disease, hypertrophic cirrhosis of the liver). Possibly the fibro-adenic should be regarded as a natural healing process instituted by Nature to counteract the increased hæmolytic powers of the spleen. In some of the cases of hypertrophic cirrhosis of the liver the changes of structure appeared to be very slight; in those previously described they recalled the alterations found in cases of toluylendiamin poisoning. Apparently, all three diseases—pernicious anæmia, hæmolytic icterus, and hypertrophic cirrhosis of the liver—may be traceable to a common genetic origin—an increased splenogenic hæmolysis, perhaps. Nevertheless, the symptoms are found to vary, whether the bone-marrow remains or not; so also may the functional activity of the liver in presence of the mischievous effects of an increased formation of bile pigments. Simultaneously with the reactionary changes (fibro-adenic) in the structure of the spleen the symptoms may also vary.

Dr. E. Ranzi exhibited some patients from whom he had removed the affected organ on account of splenomegaly. A patient of Dr. Eppinger had had a spleen of 1.300 grams removed, and the defects of growth rendered the procedure difficult. A woman, æt. 54, was also shown from whom the spleen had been removed. She had suffered for about a year from acute pains in the upper part of the abdomen, at first on the right side, afterwards on the left also. Pronounced jaundice developed in time, with itching of the integument. The splenic margin reached two fingers' breadth beyond the middle line, and the liver was also enlarged. The spleen was removed on April 15th, and weighed 1.400 gr. The upper pole had been adherent. The patient now felt quite well, and the jaundice had completely disappeared.

With regard to the dangers of extirpation of the spleen, Ranzi noted the results of ten cases of splenectomy, all of which had been performed on account of the development of splenomegaly. Of these eight were cured by the operation, the recovery being complete. Of the other two cases, one succumbed from shock four hours after the operation, and the second died of peritonitis which resulted from the perforation of a duodenal ulcer. The technical difficulties of the operation are chiefly due to circumstances, the usually important condition being the extent of adhesions. When these are absent splenectomy is quite a simple operation.

HUNGARY.

Budapest, July 12th, 1913.

On Acute Dilatation of the Heart.

A most interesting and exhaustive article by Dr. Bálint Rezsoe is contained in the "Drvosi Havi Ertesito," No. 5, Vol VII., and materially increases one's knowledge of the ætiology of acute dilatation of the heart. In all the experiments the size of the heart was measured by X-rays, so that the results must be looked upon as absolutely accurate. In the first series, a large number of patients were requested to work a specially constructed apparatus to the limits of endurance, and the skiagraph was then compared with the one taken several hours before. The endurance was greatest in convalescents from mild diseases, least in those afflicted with neurasthenia and hysteria, but an increase in cardiac volume, sufficient to warrant a diagnosis of acute dilatation, was absent, even in myocarditis and endocarditis. Only one girl, suffering from severe loss of compensation, secondary to mitral lesion, presented a marked increase in size after a walk of one hour, which considerably taxed her strength. Healthy porters were then intructed to wrestle up to exhaustion, with absolutely negative results even when circulation was embarrassed by a tight band around the abdomen and dyspnœa and cyanosis were marked. Large doses of alcohol and forced respiratory movements were also without result. The following experiments were then made with animals:—(1) A dog is forced to rotate a wheel until exhausted for several days in succession, so that the animal finally dropped as if dead. No increase in volume could be detected. (2) The vagus was irritated with the faradic current till the heart's action ceased. An acute dilatation of the ventricles set in. (3) Traumatic aortic insufficiency had no effect. (4) The introduction of air into the veins caused death by acute dilatation. (5) Saline infusion till the heart stopped beating was without influence. (6) A fatal dose of digitalin caused contraction of the ventricles and dilatation of the right auricle, with general change in shape. (7) Muscular exertion after daily venesections and starvation had no effect, but acute dilatation was very marked if the animal was fatigued after the contents of a tuberculous cavity or some other toxic material was injected. (8) Phosphorus and oil of pennyroyal caused a fatty degeneration of the heart and some relaxation, not amounting, however, to dilatation. (The same were the results in the experiments of D. de la Camp, too). (9) A strange behaviour was noticed when all extra-cardial nerves were severed, the animals became fatigued after the slightest exertion, yet the heart-shadow remained nearly normal. All the experiments proved that a normal heart, or one the seat of only slight lesions, is incapable of over-distension, no matter how its working capacity is taxed. The records of a number of cases of dilatation observed by the author are in accord with this, for in all three was some serious lesion. In the non-fatal cases this may not be evident; the heart may possess its normal size and beat normally after the attack is over; but a careful history and examination will always disclose some previous—not necessarily severe—infection or some chronic systemic derangement which is sure to alter the heart-muscle. It cannot, however, be denied that the healthy heart may occasionally dilate when several injurious factors act upon it at the same time. Thus, besides over-exertion, there may also be the coincident ingestion of too much fluid. Soldiers marching long distances, when heavily laden, sometimes suffer from attacks, and the effects of rarefied air in mountains are undeniable, though not readily explained.

Cardiac Disturbances and Diseases of the Biliary Passages.

There have been observed many cases of biliary colic in which the cardinal symptoms of the affection, such as pain on the right side and the like, have been absent, the attacks being accompanied by cardiac or pulmonary phenomena, such as asthma, disturbance of the pulse rate, and others. In some cases there even appeared an insufficiency of one of the cardiac valves, which, however, disappeared with the cessation of the attack. Dr. Berkovits reports three cases of biliary calculi in which these reflex cardio-pulmonary disturbances were quite marked during the attacks of colic. Thus, one of them suffered from very severe dyspnœa, during which there was a high degree of oxygen hunger. It is of interest to note that physical examination during one of these attacks of dyspnœa failed to detect any difficulty in the ingress of air to the lungs. The heart showed an elargement, principally of the right ventricle, accentuation of the second pulmonary sound, and insufficiency of the mitral valve. As regards the pathogenesis of these disturbances, Dr. Berkovits considers them under three heads: Mechanical, poisonous (intoxication), and reflex. Of these he regards the last of the greatest importance. It is considered that the mucous membrane of the biliary ducts serves as the starting point of the reflex act. The muscles of the biliary ducts and sphincter at the junction of the ductus choledochus and the duodenum are innervated by the vagus and sympathicus. This was proven experimentally, as well as during a laparotomy, when the operator, by manipulating the region about the ductus choledochus caused repeatedly cessation of the right pulse, which reappeared as soon as the manipulations were stopped. The sympathetic is thought to be the path through which the reflex travels. In the absence of any causative agencies in the lungs and heart in certain cases of dyspnœa, Berkovits advises to remember the possibility of cholelithiasis as the underlying cause of the condition.

CANADA.

Toronto, June 24th, 1913.

Opening of Toronto General Hospital.

It was but a few years ago that Toronto was more inadequately supplied with hospitals than any city of a like size in the civilised world. Now she is as well supplied as any city, and better than most cities. This remarkable change has been brought about within the past five years. However, before describing the magnificent hospital buildings which were opened on June 20th, it will be fitting to say a few words concerning the opening ceremony. This was performed by the Lieutenant-Governor of Ontario, Sir John Gibson, who, escorted by a company of medical men and trustees, unlocked with a golden key the front doors of the main building. In the address of Sir John Gibson, a note of regret was sounded that the Duke of Connaught had not been able to open the hospital, as he had fully intended. The Lieutenant-Governor paid a high compliment to Mr. Flavelle, to whom was chiefly due the credit for the erection of the new buildings, and it was gratifying to think, said Sir John, that there were men in Toronto like J. Ross Robertson, of everlasting fame and reputation; Mr. W. J. Gage, and the donors to the General and other hospitals who have demonstrated that the acquisition of wealth means that the people as a whole may acquire benefits which they would not otherwise receive.

Your correspondent, on Saturday, June 21st, went through the new buildings, and was greatly impressed by all he saw, and will endeavour to explain the general plan and scope of this, one of the largest and perhaps the most fully-equipped and most complete general hospital in the world. The main buildings face College Street, and as the hospital is intended to serve as the medical school of Toronto University, the buildings of which are also on or near College Street, the situation from the students' point of view is all that can be desired. From the patients' point of view it is conveniently situated, College Street at the present time being almost in the centre of Toronto. The buildings are placed on a piece of land nine acres in extent, the cost of which was $610,000 (£102,000). The buildings provide for the accommodation of 670 in-patients. Of the 670 beds in the hospital, 150 are for private and semi-private patients, while 520 are for public ward patients. The private patients' building is a self-contained unit. and thus the remaining buildings, with grounds and gardens, are for the use of the sick poor. It is expected that the private patients' department will not only be self-supporting, but will provide a surplus revenue which will go towards the maintenance of poor patients.

The buildings comprise administration building, medical and surgical buildings, out-patients' department, pathological building, emergency building, nurses' home, and the various buildings which are necessary to the carrying on of the work of a modern hospital complete in itself. The out-patients' department, the cost of which has been borne by Mr. Cawthra Mulock, is especially worthy of notice. The surgical wards were erected at the expense of Mr. J. C. Eaton, who also provided the equipment for the surgical theatres. The emergency building, with all its equipment, was the gift of two ladies now deceased, the Misses Shields.

The necessity to provide steam and hot water for the ventilation system, the laundry, the refrigerating plant, the operating-rooms, the kitchens and the pantries, required the installation of a central steam, power and heating plant, with the hydro-electric system available as an auxiliary, using the exhaust steam for the heating system, which circulates hot water by pumps through the radiators in all the buildings.

The total cost of the buildings has been $3,450,000 (£690,000); towards this sum the Government of Ontario, on behalf of the University of Toronto, contributed $600,000 (£120,000), the City of Toronto gave $400,000 (£80,000), private citizens contributed $1,400,000 (£280,000). The proceeds of the sale of the property on which the old hospital stands will be applied to liquidate the debt of $1,050,000 (£210,000), leaving a sum to be raised of about $800,000 (£160,000). However, it as announced at the opening ceremony that the City Council had recommended that a further grant of $210,000 (£42,000), be made, and that subscriptions of $50,000 (£10,000) had been promised. Thus it seems likely that in a short time the hospital will be free from debt.

From a necessarily somewhat cursory inspection, the impression was conveyed that nothing has been left undone to build and equip a thoroughly efficient hospital and medical school. The wards and corridors are roomy, airy, and well ventilated. Perhaps the out-patients' department is that which most strikes the skilled observer. It may be stated with little fear of contradiction that it is the most nearly perfect example of such a department as yet built. In the space at the disposal of a correspondent, it would be impossible to enter into details relating to the construction, arrangement, equipment and furnishing of this great institution. Suffice it to say that it is one of which the originators and citizens of Toronto may well be proud and is a striking object lesson on the intelligent co-operation of state, city and private zeal and munificence.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

EDINBURGH UNIVERSITY GRADUATION CEREMONIAL.

THE degrees in medicine and science were conferred on Friday last, July 11th, in the McEwan Hall, by Principal Sir William Turner, Vice-Chancellor of the University. There were 68 degrees of M.D., 3 of M.S., 98 of M.B., Ch.B., 25 of B.Sc., and a few arts and philosophy degrees. After the graduates had been duly capped and a number of scholarships and prizes awarded, Professor Robinson, the promoter, delivered the customary address, in the course of which he said that while for many years the conditions under which new graduates faced their work had remained practically unchanged, those who took their medical degrees that day joined a profession which had been made a pawn in the game of party politics—a business which appeared to have no regard for truth or justice unless these happened to be associated with party advantage. It was necessary for the medical profession to combine in the interests of public health, otherwise the interests of the profession would be bartered for political advantage. It seemed not improbable that the time would come when medical men would have to fight for proper hours of labour and relief from clerical work to get time to attend to the advancing knowledge of their profession.

THE INSURANCE ACT.

The Royal Faculty of Physicians and Surgeons of Glasgow have intimated to the Prime Minister and to all members of Parliament a resolution passed at the last meeting of the Faculty, with an expression of their hope that it will be favourably considered. The resolution reads: "That the Royal Faculty of Physicians and Surgeons is of opinion that in connection with the forthcoming Bill to amend the National Health Insurance Act the Government should invite the opinion of the Royal Medical and Surgical Corporations as to the amendments, if any, relating to the medical sections of the Act, which would ensure efficient medical and surgical work among insured persons."

From a review of the first year's work of the Act in Leith by the Chairman of the Burgh Insurance Committee, it seems that during January, February, and March the average numbers of visits and attendance at the surgery per doctor per day were between 3 and 4, 6 and 7 respectively. The number of insured persons was 26,427, of whom 6,065 received treatment in the shape of nearly 17,000 visits. For this the sum of £2,030 was due to the doctors. The average number of patients per doctor on the Leith panel was about 1,000; the figure 539 given by the Commissioners being due, as was suggested in this column a week or two ago, to the presence of a number of Edinburgh doctors with very few Leith patients on the Leith panel.

NEW PROFESSOR OF PHYSICS IN EDINBURGH.

Prof. C. G. Barda, F.R.S., King's College, London, has been elected to the vacant chair of Natural Philosophy in Edinburgh. Prof. Barda is a distinguished physicist, having held the Bibby Scholarship, the Oliver Lodge Fellowship, and an 1851 Exhibition Fellowship. He is a Fellow of the Royal Society, and his work on radio-activity has been recognised widely here, in France, and in Germany.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE HONORARY STAFF OF THE MOUNT VERNON HOSPITAL AND THE COMMITTEE OF MANAGEMENT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As Chairman of the Medical Board of the Mount Vernon Hospital for Consumption and Diseases of the Chest, I am desired by the Board to forward to you the enclosed letter with the view to publication in the columns of your journal.

I am, Sir, yours truly,
F. W. TUNNICLIFFE.

Harley Street, W.
July 9th, 1913.

[ENCLOSURE.]

To the Committee of Management of the Mount Vernon Hospital.

Gentlemen,—We, the undersigned, members of the honorary medical staff of the Mount Vernon Hospital, greatly regret that we feel it our duty to protest strongly against the attitude which for the past few months the Committee of Management has adopted in reference to the Medical Board and its recommendations.

The recent summary dismissal of two physicians from their appointments at Northwood is not only in direct opposition to the recommendation of the Medical Board, but, as we are advised, is illegal and *ultra vires.*

Another objectionable feature of the conduct of the Committee of Management towards the Medical Board was the refusal of the former to accede to the request of the Medical Board of May 6th, 1913, to hold a joint conference, at which it was the intention of the Board to put the above and other questions before the Committee of Management in an amicable and in no sense contentious spirit, feeling, as they did, that their correct solution was vital to the interests of the hospital.

In conclusion, we, the undersigned, as a protest against the illegality and injustice of the recent actions of the Committee of Management, beg to give notice of our intentions to resign our position as honorary medical officers to the hospital on July 20th next, but without prejudice to any steps we may subsequently legally be advised to take, especially with regard to the institution of an inquiry into the manage- of the hospital. We take this course with the profoundest regret, inasmuch as it involves the severance of our connection with an institution the interests of which we have had deeply at heart and to which some, inded many, of us have given a no inconsiderable portion of the best part of our professional lives.

MEMORIAL TO THE LATE DR. GEORGE ALEXANDER GIBSON.

To the Editor of The Medical Press and Circular

Sir,—Friends of the late Dr. George Alexander Gibson will be pleased to learn that the recent appeal for a fund to establish a "Gibson Memorial Lectureship" has already met with a most gratifying response.

A meeting of those subscribers who have intimated that they wish to join the General Committee of the Memorial Fund will be convened some time in October. After this the subscription list will be closed, and a copy, together with the resolutions of the General Committee, will be sent to each subscriber.

In case there may be any of the late Dr. Gibson's friends who did not receive an intimation and who might desire to subscribe, I may add that the Honorary Treasurer of the Memorial Fund is Mr. A. Gray Muir, W.S., 19, York Place, Edinburgh.

I am, etc.,
George A. Berry,
Convenor of the Executive Committee.
31 Drumsheugh Gardens, Edinburgh.
July 9th, 1913.

ALCOHOLIC QUACK MEDICINES.

To the Editor of The Medical Press and Circular.

Sir,—Medical temperance reformers are under an old and growing obligation to your paper for the consistent and persistent fashion in which you have always exposed the evils of alcoholic intemperance. Your forcible, albeit brief and pithy editorial of June 18th, headed "In Vino ?" deserves, like many of your recent utterances, to be brought before the notice of the various temperance societies, and the organs that represent them. There can be no doubt about the mischief that is being wrought by the traffic in quack cures the sole potent ingredient of which is alcohol. In a law case a short time ago it was stated in evidence that between £50,000 and £100,000 a year was being spent in the advertising of a single one of these compounds. There are scores on the market. There are, of course, legitimate pharmaceutical proprietary articles in which alcohol forms a chief ingredient, but these are intended for use by medical men alone who employ them after diagnosis as therapeutical agents in the few forms of disease in which a stimulant of the kind is needed. If there is any one fact in medicine that is demonstrated beyond controversy it is the fact that alcohol cannot be a cure for any disease, and that in every case of disease of whatever origin where the chief subjective symptom is depression, alcohol acts as a poison of the most pernicious character. It is as positive cures for diseases of this kind that many alcoholic nostrums are mostly advertised. They must be inflicting injury, and deadly injury, upon thousands of wretched sufferers whose maladies might be relieved by medical science. They must be acting as the cause of a vast amount of chronic inebriety, and leading great numbers of innocent people to acquire a vice to which they may become enslaved. Convincing evidence to this effect was given before the Select Committee by Dr. Mary Sturge. Why do not the temperance societies take up this question? Why do not their journalistic representatives strive to force it upon the attention of the legislature? It seems probable that in such a crusade they would have the leading journal on their side. In a leading article a year or two ago "On the Care of the Inebriate," the *Times* discussed this question. It pointed out that :—" Every inebriate passes through an early or preliminary stage; and the time-honoured principle, to oppose beginnings, might in very many cases be applied to him successfully. In the case of drugs much might be done by a strict interpretation and enforcement of the laws against the sale of poisons, and by the absolute prohibition of the many quack medicines, advertised as remedies for various complaints, which owe their popularity to the cocaine, the morphia, or the alcohol which they contain, and to the temporary and delusive sense of comfort which they afford. Preparations of this class are the frequent causes of an ultimate resort to the same agents in stronger forms; just as the practice of taking irregular drinks at all periods for so-called good-fellowship, or for 'any other reason why,' is a common precursor of habitual intoxication."

I am, Sir,
Yours truly,
Temperance Reformer.

June 20th.

MARRIAGE, BIRTH AND DEATH RATES IN 1912.

To the Editor of The Medical Press and Circular

Sir,—In the letters on this subject which you have so frequently in late years favoured me by publishing I have invariably insisted upon the fact which forms the opening statement in your excellent leader of to-day—namely, that the steady decrease in the birthrate forms "a problem that strikes deep into the roots of our national prosperity—nay, of our very existence." For more years than I care to count—but it is at least a quarter of a century since my first letter on the subject appeared in your pages—I have been a student of the question, keeping my attention mainly fixed on the phenomena being displayed in France. The French have carried the idea of restriction of births to its logical conclusion, or even beyond that point. If it were not for the presence on the French soil of 1,500,000 foreigners constantly being naturalised and assimilated, the population would now show an annual decrease. The average number of children per family does not exceed two. With regard to the effects upon the quality of the race, I believe that any system of artificial selection not based upon and controlled by science must lead to deterioration; and I believe that deterioration is progressing among the French. With regard to the effects upon national stability, the lack of an exuberant population has rendered France, without the help of allies, unable to defend herself in a fight to a finish against Germany, and has rendered her incapable of holding for long the vast overseas dominions which she now possesses, and to which she is unable to supply any emigrants. We are following the example of France. We are guarding, keeping alive, and helping towards marriage the early born of the possible broods, and as these are not as a rule the best bred physiologically, we are carrying on a system of artificial selection of the wrong sort—a system which can have only one result. Our Colonies and dominions contain millions of unpopulated fertile square miles of land under magnificent climates. Possibly Canada may remain British, but unless we people Australasia and Africa we cannot hope to hold them for long. They could take all our normal surplus for hundreds of years. If in the course of the centuries the population question should become acute science will have put into the hands of posterity the means to deal with it. But what has posterity done for us that we should sacrifice for posterity? Let us eat, drink, and be merry, for to-morrow we die.

I am, Sir, yours truly,
A Student of Sociology.

July 2nd, 1913.

SPECIAL REPORTS.

REPORT OF THE REGISTRAR-GENERAL FOR IRELAND.

The annual report of the Registrar-General for Ireland, which contains a general abstract of the numbers of marriages, births, and deaths registered in Ireland during the year 1912, has been laid on the Table of the House of Commons. The report shows:—

(*a*) An increase of 1,102 in the population of Ireland in the middle of 1912, as compared with that in the middle of the preceding year.

(*b*) The lowest annual death-rate from all causes recorded for Ireland since 1871, viz., 16.46 per 1,000 of the population.

(*c*) The lowest annual death-rate from tuberculous disease on record, viz., 2.15 per 1,000, the next lowest rate from this disease being 2.20 per 1,000 in the previous year (1911). The number of deaths caused by tuberculous disease in 1912 is 186 less than 1911, and 3,257 less than the number recorded in 1904, and

(*d*) A decrease in infant mortality from 94 per 1,000 births registered in 1911 to 86 per 1,000 births registered in 1912. This is the lowest infant mortality rate recorded for Ireland. The highest infant mortality rate was in the year 1880—namely, 112.

The marriages registered in Ireland during the year 1912 numbered 23,283; the births, 101,035; and the deaths, 72,187. The marriage-rate was 5.31 per 1,000 of the estimated population, showing a decrease of 0.04, as compared with that for the year 1911, but an increase of 0.12 as compared with the average rate for the ten years, 1902-1911; the birth-rate was 23.0 per 1,000 of the estimated population, being 0.2 under that for the preceding year, and 0.3 under the average rates for the ten years 1902-1911; and the death-rate (16.46 per 1,000) was 0.07 below the rate for the preceding year, and 0.83 below the average rate for the ten years 1902-1911.

The report informs us that in the aggregate the deaths from tuberculosis numbered 9,437, or less by 186 than the number registered in the year 1911. The total is equivalent to 2.15 per 1,000 of the population of Ireland estimated to the middle of the year 1912, as against 2.20 per 1,000 in 1911. From the year 1904, when the death-rate from tuberculosis was 2.9 per 1,000 the rate has fallen steadily. It declined to 2.7 in each of the years 1905, 1906, and 1907; to 2.6 in 1908, to 2.4 in 1909, to 2.3 in 1910, and, as already mentioned, from 2.20 in 1911 to 2.15 per 1,000 in 1912, the period now under notice. A subsequent table shows us that of the 9,437 deaths from tuberculosis, 4,682 were of males, and 4,755 were of females; that there was a decrease of 66 deaths in the Province of Leinster, an increase of 10 deaths in Munster, a decrease of 93 in Ulster, and a decrease of 37 in Connaught. It may also be seen amongst the principal causes of death, that tuberculosis is the second highest, standing in between old age, the highest, and heart disease, the third highest cause of death. The death-rate from tuberculosis in England and Wales, in Scotland and in Ireland, are compared since the year 1864. In the year 1911 the rate in Ireland was 2.2, in Scotland 1.7, and in England 1.5 per 1,000 of the respective estimated populations of the three countries.

Dealing with pulmonary tuberculosis, the report informs us that altogether the deaths included under this heading amounted to 7,452—of males, 3,671, and of females, 3,781, corresponding to the following rates:—1.70, 1.68, and 1.72 per 1,000 of the respective populations. In the year 1911 the total number of deaths from pulmonary tuberculosis was 7,584—of males, 3,702, and of females, 3,882. These figures correspond to the following rates:—1.73, 1.70, and 1.77 respectively. The highest death-rate from pulmonary tuberculosis, we are informed, for both males and females, was between the ages of 25 and 35 years. For both sexes it was 3.13 per 1,000—for males, 3.09 per 1,000, and for females, 3.17 per 1,000.

There were 8,727 deaths of infants under one year of age registered for the whole of Ireland. Of this number, 4,991 were deaths of male infants, and 3,736 were deaths of female infants. The total is equivalent to a rate of 86 per 1,000 of all births registered in the year, and is 8 per cent. under the rate for 1911. In the year 1911 the infant mortality rate was 94 per 1,000 births, and the average infant mortality rate for the ten years, 1902-11, was 0.5 per 1,000 births. It appears that for Ireland the infant mortality rate was 86.4 per 1,000, that in the "civic" unions it was 115.2 per 1,000, and that in the remaining unions of Ireland it was 66.5 per 1,000. In the year 1911 the figures for the "civic" and remaining unions were 128.4 per 1,000, and 70.9 per 1,000 respectively.

It would appear from the returns collected and forwarded to this Department by the Royal Irish Constabulary and the Metropolitan Police, who acted as enumerators at the several Irish seaports, that the number of emigrants (natives of Ireland) who left the ports of Ireland during the year 1912 was 29,344, of whom 15,325 were males and 14,019 females. Of the total emigrants, 3,855 were natives of the provinces of Leinster, 7,167 of Munster, 11,852 of Ulster, and 6,470 of Connaught. In 1912, of the 29,344 emigrants, 7.6 per cent. were under 15 years of age, 85.9 per cent. were between 15 and 35 years old, and 6.5 per cent. were 35 years or upwards.

REVIEWS OF BOOKS.

CABOT'S PHYSICAL DIAGNOSIS. (*a*)

We welcome the publication of the fifth edition of this well-known standard work, which has been revised and reset throughout, with the addition of twenty-three new illustrations. Little can be added to the tokens of approbation with which preceding editions of Dr. Cabot's book have been greeted, for all of the editions carry the impress of a master-mind, and the individuality of the author finds expression in every line of the text. The continued success of this book amidst considerable competition rests upon its practical utility. No space has been given to the description of tests which the author has discarded as valueless, and no *technique* has been described with which he is not thoroughly acquainted. "All that I have described," says Dr. Cabot in his preface, "I know by prolonged use." The most important additions are those which deal with the circulatory system and the methods of recording the variations which occur therein in the form of arteriograms, phlebograms and electrocardiograms. Here, more than ever, is the soundness of the author's judgment evidenced when he remarks, "I feel convinced by my own experience

---

(*a*) "Physical Diagnosis." By Richard C. Cabot, M.D., Assistant Professor of Medicine in Harvard University. Fifth edition. Royal 8vo. Pp. xxii. and 519, with five plates and 268 figures in the text. London: Bailliere, Tindall and Cox. 1913. Price 15s. net.

with tracings of the venous pulse and by my study of others' work with electrocardiograms that neither method is likely ever to be used by the practitioner for whom this book is intended." Hereupon follows an excellent critical summary of the results accomplished by these newer methods. The sections on blood pressure and the arrhythmias, as well as those on neoplasms of the lung and pleura, on subphrenic abscess and peptic ulcer have been recast, and X-ray examination of the stomach by the bismuth meal receives more adequate notice in this edition. The book is well and clearly printed in good type, but occasional errors are found—as in the spelling of the heading to Chapter VIII.—which appear to occur almost inevitably, despite the most careful revision of proof-sheets. A careful index is not the least valuable part of the book.

OPERATIVE SURGERY. (a)

MR. Binnie's "Operative Surgery" first appeared in 1905 as a comparatively small work in one volume, which at that time took no cognisance of operations on bones and joints. Later, Vol. II. was added; this dealt for the most part with the latter subject; and the present book, 8vo. in size, is the fifth publication of Vol. I., and the second of Vol. II., bound together as the fifth edition.

The work is conveniently divided into six parts. The first five of these discuss the surgery of the head and neck, the thorax, the abdomen, the uro-genital system, and in a more limited space that of the spine. Part VI., "Unclassified Topics," comprises the latter half of the work, and is devoted to abscesses, drainage, nerves, arteries, veins, bones and joints.

The writer's idea apparently is to make his work as modern as possible. He therefore does not include many of the older operations which are found in most systematic text-books. He has succeeded in producing what may be described as a valuable summary of surgical annuals. His judgment in selecting material is sound, and his general advice good. Some of his text and a number of his illustrations have been supplied to him by their original authors.

That the book has found a sphere of usefulness is apparent from the number of editions it has gone through in a comparatively short time. It is essentially a work for the junior surgeon, who must frequently meet difficult, and to him unusual cases, where he has to make up his mind which of a number of methods is the most suitable for his immediate purpose. Mr. Binnie describes a variety of procedures for each operation—not in a verbose manner, but clearly and concisely. Each operation is rationally divided into stages, the descriptions of which are printed in separate paragraphs as Steps 1, 2, 3, etc., so that one is likely to remember the sequence without undue effort. The work has also the advantage of being profusely and suitably illustrated to ensure clearness with the minimum of descriptive text.

Beside the fact already mentioned, that the work is now one large volume instead of two small ones, and that some fresh articles which have appeared during the last three years have been included to bring it up to date, the text of the fifth edition does not differ in the main from the previous ones. There are, however, over 100 additional illustrations, some of them coloured. Payr's operation for hydrocephalus, operations on the pituitary body, the injection treatment of tic douloureux, and many other points of *technique* are added. Some of these are still *sub judice*, others will at once appeal to the surgeon.

LEFTWICH'S TABULAR DIAGNOSIS. (b)

THIS collection of 350 tables of diagnosis by the author of the well-known "Index of Symptoms" offers great and obvious advantages to the busy practitioner, for whom the book has been written. The doctor who has been in practice for some years is likely at times to feel his deficiencies in diagnosis, and, since few can give adequate time for post-graduate classes or for systematic reading, some kind of book is required which will provide the knowledge desired with a minimum expenditure of time and trouble. For rapid reference there is nothing so serviceable as a classification in tabular form, and we can heartily recommend this book for its general utility. Each table is divided into three columns. In the first column appears the symptom, organ, or region, and in the other two the word or phrase which qualifies it. This arrangement not only lessens the amount of reading necessary, and consequently of time spent in consulting the table, but it has the added advantage that the reader in search of a particular symptom is able to find it at once by glancing down the first column. To make the work complete, several little-known signs have been inserted, and many of the less known diseases have been included. The tables are numbered and placed as far as possible in alphabetical order, and the book answers to various practical tests which have been applied. Perhaps in places details may be criticised, such as the table on page 269 of the signs of "phthisis, early," which, by the way, one would rather see styled "pulmonary tuberculosis, early," the signs given being those of already well-marked consolidation. Calmette's test, too, which has largely fallen into disuse, would be far better replaced by the subcutaneous tuberculin test, or failing this by Von Pirquet's cutaneous reaction, both of these latter having greater precision in diagnosis, with no likelihood of untoward results. If this work is consulted by those who realise that there is no "always" and no "never" in clinical medicine, the tables contained therein, though necessarily somewhat dogmatic, will be appreciated at their true value.

RESEARCHES IN COLOUR VISION. (a)

THIS valuable and interesting volume embodies the substance of the communications which its distinguished author has been making to the Royal Society during the past quarter of a century, or so, on a peculiarly important and very much debated—and disputed—subject of physical and physiological investigation. While it is all too true, indeed, as inquiring and conscientious readers have learned to their cost (in time and thought, strenuously laboured and so often wofully wasted), that "other theories of colour vision, physiological and psychological, have been offered to the Press"—and with persistent claims to the right of extinction of all rivals—Sir William Abney is still able to present a good case for the theory which he has himself championed so long and so faithfully. Accordingly, the principal inducement which led to the publication of the present volume—superadded to the requests of eager inquirers for collected copies of his valuable papers—was the laudably honest wish to demonstrate the persistent vitality of the trichromatic theory; which, as he says, with truth as well as with justly laudable pride, "does not yet require a funeral oration over its remains."

A seven-league stride in the expansion and strengthening of the basis of this physical theory was carried out by the author's elaborate (and necessarily, in the hands of a skilled and enthusiastic physicist, meticulously accurate) measurement of the three sensations produced by the respective spectral colours. Various problems, previously unsolved, have been quite satisfactorily determined by the data thus provided. With a dignified exclusiveness, which we feel bound to respect, the author has refrained from the criticism of rival theories; while accounting by means of his own physical theory, not only for colour sensations, but for the associated phenomena of colour blindness, colour fatigue; and the collateral phenomena of healthy and of defective function. And he recognises the limitations of his position with the intellectual precision of a philosopher, and the candour of a reliable scientific soothsayer: "The trichromatic theory offers the truth; but the physiologists must add their quota to it to make it the whole truth. There may be difficulties in welding together the physical and physiological aspects of colour vision to make a perfect theory, but it will be effected."

(a) "Manual of Operative Surgery." By John Fairbairn Binnie, A.M., C.M.Aberdeen, with 1,365 illustrations. Pp. x. and 1,153. London: H. K. Lewis. 1912. Price 30s. net.

(b) "Tabular Diagnosis: An Aid to Rapid Differential Diagnosis of Disease." By Ralph Winnington Leftwich, M.D., late Assistant Physician to the East London Children's Hospital. Pp. 359. London: Edward Arnold. 1913. Price 7s. 6d. net.

(a) "Researches in Colour Vision and the Trichromatic Theory." By Sir William Abney, K.C.B., D.Sc., D.C.L., F.R.S. With four coloured plates and other illustrations. Longmans, Green and Co.: London, New York, Bombay and Calcutta. 1913.

The author, wisely as well as modestly, avoids discussion of such matters as "some after-effects of light on the retina which, so far, do not lend themselves to exact measurement by physical means." Such discrimination surely does present an edifying contrast to the methods of the physiological, and the psychological, quack; each of whom we have had the painful experience of consulting in the effort—temporarily ineffectual, in greater or less degree—to expand the boundaries of our own little domain of optical-*plus*-ophthalmological enlightenment. Being human, he is, of course, inevitably open to the mental influences of the colouring media placed before the mind's eye; by the action of the "eidolon of the cave" within, and of that "of the market-place" without. Accordingly, we are not surprised to find the *ad hominem* argument or "it is hard to believe" brought up (even in the preface) to corroborate the apparent probability of the identity of the action of light on the retina with that which it produces on the inanimate photographic plate; while the author, like a truly philosophic judge, declines to make a definite ruling.

The introductory chapters, which deal with the basic data, are models of concentrated knowledge; and the descriptions of the physical apparatus employed, and of the various items of research carried out with their aid, are above all captious criticism. General questions, such as suggest themselves to every intelligent observer of nature, necessarily crop up in connection with discussion of the data afforded by the most enlightening of all the senses. The azure hue of the sky is one. Sir William Abney is disposed to believe "that the main sources from which the blueness is derived are dust and particles of water which are in a semi-vaporised condition. These would amply account for it. We have often good circumstantial evidence before us that such water particles will produce the effect." The author does not fail to refer to the blue haze in which distant hills are usually invested, and proceeds to point out that "When the atmosphere is moist, it is a matter of common observation that distant hills show their local colour, and stand out so that one can 'almost touch them.'" We hardly think that the expression "stand out" suits the phenomenon very well; the phraseology of the metrical "Prognostics of Rain," which were formulated by the poetic ancestor of the imaginative inventor of the evolutionary "Origin of Species," presents the physical change more vividly:—

> "Loud quack the ducks, the peacocks cry,
> The distant hills are looking nigh."

We would like to have Sir William Abney's explanation of the influence of the *size* of the floating water particles in the production of the telescopic effect which—like so many other of the familiar phenomena which have evermore been with us—remains still unexplained, and almost uncommented. The writer of this notice could not help recalling in this connection one of the items of inspired information conveyed to him on this head in the far-back days of his curriculum, when ozone was fairly young; and, like other impressive juvenilities, credited with many unverifiable powers. The University Professor of Chemistry (and F.R.S.) thought that the floating vegetable and marine matters in the atmosphere probably provided the permanent starch-iodine reaction. The Professor of Physics pointed out when consulted, and with explosive merriment, that under such influence the sky should be red!

But such comment is relatively trifling gossip—the reviewer must say something, critical or relevant (both or neither)—in the presence of a volume which we unhesitatingly pronounce to be one of the most important contributions to the science, and literature, and experimental art, of physiological optics that has appeared since the publication of the monumental work of Helmholtz. So we close this all too trifling notice with a cordial expression of thanks to Sir William Abney for the brilliantly intellectual treat which he has afforded us.

THE INSANITY OF GENIUS. (a)

The claim advanced by Dr. Hollander in his rather elaborated preface to this volume, that the late Mr. Nisbet "was a close observer of mind and character," seems to be fairly well borne out by an examination of his work. He was undoubtedly an enthusiast in his way. It might readily be surmised that the germ of this intellectual feature was supplied through contact with Dr. Hollander who informs us that: "He availed himself of my investigations into the functions of the brain"; and the inspiration of culture and development might provisionally be accounted for by intellectual "radiation." Anyway, the editor of this posthumous edition informs us—approvingly, of course—that the author "held that all manifestations of human activity—physical, moral and intellectual—have their *seat* in the brain and nervous system"; and we must point out at the start that the view thus summarised might easily have been expressed in phraseology more precise as to its ratiocination, and more accurate as to its grammar and diction. If the writer had substituted for the term "seat"—which we have purposely italicised—the other monosyllable, *source*, the position so defined could be much more readily defended. Nor do we appreciate very highly the suggestion of impregnability of another logical position—inclusive of an assumption—which Dr. Hollander immediately afterwards proceeds to occupy: "Genius is nearly always limited to the predominance of one or more brain-powers. Could this be if the brain had not multiplex functions?" On the other hand, however, we cordially sympathise with his appreciation of the work of Gall, and his lofty estimate of the personality and achievements of that enthusiastic pioneer of modern neurology, whose publications have, ever since their appearance, been utilised as the great quarry of "original" discovery by the smuggling and looting (and less honourable) Dick Turpins of the rugged and thorny pathways of neural anatomy and physiology. He anticipated, by suggestion and experiment, the differentiation of motor and sensory nerve-roots and paths of conduction, which constituted the famous *discoveries* of Sir Charles Bell; and definitely localised the primordial motor centre of the cerebral cortex, which in time came to be known—with the usual irony of reputation, scientific and other—as "Broca's space." A good illustration is surely found in the record of Franz Joseph Gall of the truth of the bitter cynicism enunciated by Jonathan Swift—whose *sæva indignatio* was, all too obviously, evolved from his own personal experience: "Whenever a true genius appears in the world, you may always know him by this sign, that all the asses are arrayed in confederacy against him."

We must say, in conclusion, that we have nowhere failed to find the contents of this volume highly suggestive, even where not quite reliably instructive; and on that account (even alone) we do not hesitate to affirm that it thoroughly deserves the popularity which it has obviously succeeded in securing.

MEDICAL NEWS & PASS LISTS.

The Royal College of Surgeons of England.

At a quarterly meeting of the Council of the Royal College of Surgeons last week, with Sir Rickman J. Godlee, President, in the chair, Mr. J. Ernest Lane, Mr. L. A. Dunn, Mr. Jonathan Hutchinson, and Mr. H. J. Waring, the four Fellows recently elected, took their seats as members of the Council.

Sir Rickman J. Godlee was re-elected President and Mr. G. H. Makins, C.B., and Sir Frederic Eve were elected Vice-Presidents of the College. Sir Frederic Eve was also elected a member of the Executive Committee of the Imperial Cancer Research Fund, and

---

(a) "The Insanity of Genius and the General Irregularity of Human Faculty physiologically Considered." By J. F. Nisbet. With a preface by Bernard Hollander, M.D. Pp. 341. London: Stanley Paul and Co. Price 5s. net.

Mr. R. Clement Lucas was appointed the representative of the college on the Council of the Queen Victoria's Jubilee Institute for Nurses. The Council elected the following professors and lecturers for the ensuing collegiate year:—Hunterian Professors—Mr. Arthur Keith, Mr. Hastings Gilford (Reading), Mr. C. Mansell Moulin, Mr. E. W. Hey Groves (Bristol), Mr. A. R. Short (Bristol), and Mr. H. B. Whitehouse (Birmingham); Arris and Gale Lecturers—Mr. F. Wood Jones and Mr. David Waterston; Erasmus Wilson Lecturer—Mr. S. G. Shattock; Arnott Demonstrator—Mr. Arthur Keith; and Odontological Demonstrator—Mr. J. F. Colyer.

The following members of the college were admitted Fellows:—P. S. Foster, M.B., L.R.C.P., Otago Univ. and London Hosp., and P. H. Mitchener, M.B.Lond., L.R.C.P., St Thomas's.

The following were admitted members:—G. H. Alabaster, Birm. Univ.; P. H. Berry, B.A.Camb., Guy's; D. V. Pickering, B.A.Camb., Guy's; and T. O. Williams, Liverpool Univ.

G. C. Gell, Middlesex and R. Dental Hosps., was admitted a Licentiate in Dental Surgery.

The Council passed a resolution expressing deep regret at the death of Sir Jonathan Hutchinson, past president of the college, and recording their "appreciation of his untiring industry, the extent and accuracy of his observations, his eminence in many of the special departments of surgery, and the important discoveries which will always be associated with his name."

It was decided to publish a revised edition of the Museum Guide with additional illustrations.

University of St. Andrews.

The following have obtained the M.B. and the Ch.B. degrees, having passed the final examination in Medicine, Surgery and Midwifery:—David A. D. Kennedy, David Matthew, Robert Nicoll, William B. Patterson, Ruth E. Proctor, John C. Robertson, Jessie M. Valentine.

The Closing of King's College Hospital.

At midnight on Monday last King's College Hospital closed its doors. It reopens at Denmark Hill in October, where there will be 600 beds, in place of 250 beds at the old building near the Strand.

Earlier in the evening there was a reunion of old and present students, which was followed by a supper and a concert, at which Professor Urban Pritchard presided, and in giving the toast, "The Old Hospital and the New," he spoke of the enormous advance of medicine and surgery since he was first associated with the hospital 50 years ago. King's College had always been great on surgery, and it had also been the first hospital to have special departments. The formation of special departments was the death-blow to the old building, for they were constantly asking for more beds.

Mr. W. Smith (Chairman of the Hospital) said that although that celebration was partly one of sadness, yet it was also one of great hope for the future.

Sir W. Watson Cheyne, an old student, also spoke.

The Australian Institute of Tropical Medicine.

The Australian Institute of Tropical Medicine at Townsville. Sydney, which was founded as the result of an amalgamation of the schemes of Professor Anderson Stuart, of Sydney, and of the ex-Bishop of North Queensland, and now mainly supported by the Commonwealth, was recently opened by Sir William Macgregor. The Institute is working at the possibility of peopling Northern Australia with a working white population. The Australian Universities, in conjunction with the Institute, grant a diploma in tropical medicine.

Child Protection Congress.

The International Congress for the Protection of Children will be held in Brussels from July 23rd to July 26th, under the patronage of the King and Queen of the Belgians, with M. Adolphe Prins, Professor at Brussels University, as President. The Organisation Committee includes: For Great Britain—Alderman Benjamin Broadbent, M.A., J.P., Huddersfield, President of the Public Health Union; Dr. MacCleary, M.D., D.P.H., Medical Officer of Health, London; Mr. J. Courtenay Lord, Chairman of the Children's Court, Birmingham; and Sir Evelyn Ruggles-Brise, K.C.B., President of the English Prisons Board. The Congress will discuss reports on the competency of children's courts, the organisation of surveyed release, abnormal children, natural children, guardianship, statistics, vulgarisation of hygienic proceedings and of puericulture notions, the protection of children and alcoholised childhood.

Benefactions to the Hospital for Special Diseases, Cambridge.

The Treasurers of the Cambridge Research Hospital for Special Diseases have received the sum of £300 from Mr. G. P. Bidder, of Trinity College, for the purchase of an additional acre of land, and a promise of £300 from Mr. J. H. Wills, of Chiddingstone Castle, Kent, for current expenses.

Royal Hospital for Incurables, Dublin.

Mr. Wm. Fry, J.P., presided last week at the annual meeting of the Royal Hospital for Incurables, Donnybrook. Mr. J. J. Thompson, Registrar, read the annual report, which stated that, large as was the institution, the Governors were forced to admit that in undertaking the care and support of 213 inmates they were only affording relief to a comparatively small number of those seeking admission. Last year the number of admissions was only a shade over one-fourth of the number of applicants. For some time past the Governors had under consideration the reconstruction of the oldest portion of the hospital, and when the additions and alterations were completed the hospital would be capable of accommodating comfortably 248 patients instead of 213 as at present. The receipts from subscriptions and donations for the year were £1,484 0s. 1d., as compared with £1,359 2s. 6d. Life Governors' payments showed a marked decrease—£378, as against £893, and bequests amounted to £593 16s. 7d., as compared with £7,175 18s. 8.

The Chairman said the Governors felt that something should be done to extend the beneficent operation of the hospital, and accordingly instructions had been given to prepare two new wings, to contain 70 beds. The Lord Lieutenant had promised to lay the foundation-stone of the new buildings on Saturday afternoon, August 30th next, and he would on that occasion be accompanied by the Countess of Aberdeen, who had done so much for hospitals in Ireland.

Universal Esperanto Medical Association.

The Organising Committee of the 17th International Medical Congress has granted the use of the Geological Laboratory in the Royal School of Mines for the meetings of the Universal Esperanto Medical Association (Tutmonda Esperantista Kuracista Asocio). The meetings will be opened by a series of short lectures in many languages on "Esperanto and the Medical Profession." Subsequently only Esperanto will be used. Intimations of papers have already been received from Professor Sims Woodhead, Dr. Nemser (St. Petersburg), Dr. Sidlovskij (Moscow), "La rezultato de la enketo pri nesukcesantaj infanoj de Moskvaj urbaj lernejoj"; Dr. Robin (Warsaw, "Pri la sondado de la duodeno"; Dr. F. W. Alexander (London), "Sanigado per marakvo kaj elektro." Others are expected. The London Esperanto Club kindly invites all Esperantist medical men to a *conversazione* and concert in St. Bride's Institute, Ludgate Circus, on Friday evening, August 8th, at 7.45. Those intending to be present at the meetings should send their names to the President of the Association, Mr. G. Jameson Johnston, F.R.C.S.I., 13 Lower Fitzwilliam Street, Dublin. The usual annual congress will take place in the University of Bern in the last week of August during the Ninth Universal Esperanto Congress.

Queen's University ot Belfast.

The following degrees were conferred on July 9th, 1913, Lord Shaftesbury, Chancellor, presiding:—

M.D. (by Thesis).—George Cooper, Joseph G. Johnston, George E. A. Mitchell.

M.Ch. (by Thesis).—Andrew Fullerton.

M.B., B.Ch., B.A.O. (Honours, Second Class).—Nathaniel Beattie, William A. L. Dunlop, Thomas W. G. Hogg, Thomas Walker. Pass: James S. Bellas, David Calwell, John F. Craig, Herbert Emerson, Henry P. Hall, Herbert M. Jackson, Gordon D. Latimer, John B. Lyle, William J. M'Cracken, Wm. M'Kim H. M'Cullagh, John J. H. Mitchell, Joseph Porter, Hugh A. Skillen, William Speedy, William Tyrrell, Thomas H. Wilson, Samuel J. Yeates.

Diploma in Public Health.—William K. Calwell, Frederick W. Craig, Thomas F. S. Fulton, David G. Gray, Richard M'Candless, William B. Purdon, James J. Robb, William B. Stevenson, Robert S. Taggart, Eustace Thorp.

FACULTY OF MEDICINE.

Scholarships.—At Third Medical Examination: A. Porter, £40; Elizabeth Walker, £30; E. G. B. Calvert, £20; R. L. Rea, £15. At Fourth Medical Examination: W. A. L. Dunlop, £30; T. W. G. Hogg, £30; Thomas Walker, £30; Nathaniel Beattie, £20.

Class Prize List—Session 1912-1913.

Anatomy.—A. C. Dickey, R. J. Rea, M. G. Thompson, J. P. M'Ginley.

Elementary Anatomy.—J. S. Smyth, H. Wild, J. Lascelles, Margaret Crawford.

Practical Anatomy.—Junior: S. J. Smyth, Dorothy I. Dobbin, Mary I. Adams, M. H. Turnbull, Margaret Crawford. Senior: J. P. M'Ginley, H. E. Magee, A. C. Dickey, J. H. B. Hogg, M. G. Thomson, D. R. Wheeler, J. H. Vance.

Physiological Chemistry.—O. M. Anderson, D. Mitchell and C. Pedlow, 1st prize; D. R. Wheeler, C. A. Whitfield, M. S. Purce.

Chemistry (Theoretical).—S. J. Smyth, S. Lees, M. Goldblatt, H. Graham, C. J. A. Woodside.

Chemistry (Practical).—H. W. Wild, S. J. Smyth, H. Graham, C. J. A. Woodside, M. Goldblatt.

Experimental Physics.—S. J. Smyth, W. Gilmore, G. H. Davis, M. H. Turnbull.

Physiology.—M. Georgina Thompson. R. J. Rea, H. E. Magee, D. Mitchell, Arabella C. Kirker, C. A. Whitfield.

Medicine.—W. J. Lascelles, E. B. Mayrs, A. Fullerton.

Surgery.—E. B. C. Mayrs, Elizabeth Robb, A. Fullerton, W. R. E. Wilson.

Midwifery.—Elizabeth Robb, A. Fullerton, Margaret Gorman, B. Lyons, W. R. E. Wilson, E. B. C. Mayrs, R. N. M'Kinstry, W. S. Lynd, W. S. B. Hay.

Pathology.—Mary A. Gallagher, W. T. M'Curry, E. G. B. Calvert, R. L. Rea, J. A. Watson.

Materia Medica.—A. Porter, E. G. B. Calvert, Elizabeth Walker, J. A. Watson, Mary Gallagher.

Hygiene.—A. Porter, Elizabeth Walker, E. G. B. Calvert, T. W. Elliott.

Organic Chemistry.—Eliza E. Ross.

FACULTIES OF SCIENCE AND MEDICINE.

Zoology (Practical).—C. J. A. Woodside, M. H. Turnbull, S. J. Smyth, S. Lees, J. Lascelles.

Zoology (Lectures).—C. J. A. Woodside, S. J. Smyth, S. Lees, S. J. Crawford, Annie E. E. Beattie.

Botany (Theoretical).—S. J. Smyth, S. Lees, C. J. A. Woodside, W. Gilmore, J. Lascelles.

Anatomy.—A. C. Dickey, H. E. Magee, M. G. Thompson, J. P. M'Ginley, D. R. Wheeler.

Botany (Practical).—C. J. A. Woodside, Annie E. E. Beattie, T. F. Ingram, W. Gilmore, S. J. Smyth.

Histology.—Margaret S. Purce, Arabella C. Kirker, W. Napier, M. G. Thompson, A. C. Dickey, J. P. M'Ginley.

Practical Pharmacy.—David Corry, W. A. Thompson, Mary A. Gallagher, Sylvia Marsh.

Medical Jurisprudence.—E. G. B. Calvert, Elizabeth S. Walker, A. Porter, W. Russell.

Operative Surgery.—G. Purce, S. Miller, Margaret Gorman, Elizabeth Robb.

University of Bristol.

The following candidates have passed the Second Examination for the Degrees of M.B., Ch.B.—Herbert Archer, Oliver C. M. Davis.

University of Edinburgh.

The following medical awards are announced:—

Thesis Gold Medallists.—O. H. Blacklay, M.D., W. E. Bullock, D.Sc., M.D., A. P. Mitchell, M.D., Ch.M., G. M. Robertson, M.D., and G. D. Whyte, M.D.

Goodsir Memorial Fellowship.—F. G. Bell, M.D., Ch.B.

Ellis Prize in Physiology.—W. E. Bullock, B.Sc., M.D.

Gunning Victoria Jubilee Prize in Physiology.—Marjory Macnaughton, B.Sc.

Ettles Scholarship.—J. N. J. Hartley, M.B., Ch.B.

Allan Fellowship in Clinical Medicine and Clinical Surgery.—E. W. Adcock, M.B., Ch.B.

Freeland Barbour Fellowship.—T. D. Inch, M.B., Ch.B.

M'Cosh Graduate's and Medical Bursaries.—D. C. Barron, B.Sc., M.B., Ch.B.

Mouat Scholarship in the Practice of Physic.—D. Martin, M.B., Ch.B.

Buchanan Scholarship in Gynæcology.—J. N. J. Hartley, M.B., Ch.B.

James Scott Scholarship in Midwifery.—T. Pullar, M.A., M.B., Ch.B.

University of Aberdeen.

At the graduation ceremony on July 8th the following Degrees in Medicine were conferred:—

Degree of Doctor of Medicine (M.D.).—James L. Gordon, M.B., C.M., William K. Irwin, M.B., Ch.B., John Inkster, M.B., Ch.B., James A. M. Clark, M.B., Ch.B., Clarence Ed. Greeson, M.B., Ch.B., Robert W. Macpherson, M.B., Ch.B., George C. Soutter, M.B., Ch.B.

Degree of Master of Surgery (Ch.M.).—Francis W. Stuart, M.B., Ch.B.

Degrees of Bachelor of Medicine (M.B.) and of Surgery (Ch.B.).—**George Riddoch, with first-class honours. Ordinary Degree: Alexander L. Aymer, Hamish D. F. Brand, William H. Brodie, Francis F. Brown, James T. Cameron, Francis J. R. Cowie, *William I. Escoffery, Winniefred M. Gray, M.A., *James M. McLaggan, George Pirie, Frederick Ritchie, *Robert S. Snowie.

**Passed Fourth Professional Examination with "Much Distinction."

*Passed Fourth Professional Examination with "Distinction."

The John Murray Medal and Scholarship (awarded to the most Distinguished Graduate (M.B.) of 1913) to George Riddoch.

The George Thompson Fellowship to Martin M. Cruickshank, M.B., Ch.B., B.Sc.

Diploma in Public Health (D.P.H.).—*Alexander M. Brown, M.B.Aberd., Elizabeth M. Edwards, M.B.Aberd., William A. Mearns, M.A., M.B.Aberd., Robert W. S. Murray, M.B.Aberd., *Robert Richards, M.B.Aberd., John Ritchie, M.D.Aberd.

*With credit.

Conjoint Examinations in Ireland.

The following candidates have passed the First Professional Examination of the Royal College of Physicians and the Royal College of Surgeons.—Arthur Briscoe, Moses Briscoe, Maurice J. Broderick, J. J. Crowe, Francis Daly, William Evans, J. Holland, Henry Hurst, Thomas P. MacDonnell, George F. Maher, Denis B. McEniry, Harold I. Mooney, B. J. Mulligan, Michael J. O'Connor, Marks M. Price, George C. E. Roe, James F. Seale, James G. Thornton, D. E. Young.

Second Professional Examination.—W. G. Thompson (honours), Miss Elizabeth Budd, John Coffey, B. J. Daunt, M. Dockrell, John A. Fretton, J. J. Hayes, B. Hirson, James McGuire, J. A. McKinnon, Miss Marjorie McMullen, Thomas Moore, Thomas F. Moran, J. F. O'Mahony, J. P. Pegum, Patrick K. I. Ryan.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

MR. R. SOAMES (Devon).—The flour of the soya bean is sufficiently poor in carbohydrates to render it useful for making bread, cakes, etc., for diabetic patients. It contains a good deal of oleaginous matter which does not become rancid on keeping for some time.

DR. ALEXANDER HAIG'S MELABOLISM THEORIES.

A Bournemouth correspondent writes to remind us that from time to time we have published articles on diet and metabolism in this journal. For many months he has been in close touch with Dr. Alexander Haig and has learnt much of great value from him. Very many practitioners are not aware how much they are losing by not studying his writings and attending his demonstrations. He is widely misunderstood. To begin with his is not a low proteid diet and he points to members of the ape tribe as examples of the enormous strength that can be built up on nuts and fruit. Fred Welsh, the champion boxer, who makes mincemeat of his most powerful opponents, lives on a diet akin to Haig's.

DUM SPIRO, SPERO (Hunts).—Careful articulation after a deep inspiration, or singing the words and then saying them directly afterwards in front of a mirror will do much to overcome the unfortunate habit of stuttering. Patience and perseverance are the keynote of success in the treatment of this form of speech defect. Attention must be paid to the general health at the same time.

Appointments.

CHAPPLE, HAROLD, M.B., M.C.Cantab., Obstetric Surgeon to Guy's Hospital.

DEPREE, H. T.,. M.B., B.C.Cantab., Honorary Anæsthetist to Guy's Hospital.

EDINGTON, G. H., M.D.Glasg., D.Sc., F.R.F.P.S.Glasg., Visiting Surgeon to the Western Infirmary, Glasgow.

FAWCETT, JOHN, M.D.Lond., F.R.C.P.Lond., Physician to Guy's Hospital.

FINLAY, D. E., M.B., B.S.Lond., Certifying Surgeon under the Factory and Workshops Acts for the Gloucester District of the County of Gloucester.

HUNT, G. H., M.B., B.Ch.Oxon., Fifth Assistant Physician to Guy's Hospital.

LANCASTER, H. F., M.D.Brux., L.R.C.P.Lond., M.R.C.S., Consulting Anæsthetist to Guy's Hospital.

SOAMES, RALPH M., M.B.Cantab., M.R.C.S., L.R.C.P.Lond., Tuberculosis Medical Officer for the county of Surrey.

TRETHOWAN, W. H., M.B., M.S.Lond., Orthopædic Surgeon to Guy's Hospital.

Vacancies.

Enniskillen Union, Lisbellaw Dispensary District.—Medical Officer. Salary £100 per annum, and Medical Officer of Health, salary £10 per annum, together with Registration and Vaccination Fees. Applications to Richey Wilson, Clerk of the Union. (See advt.)

Enniskillen Union, Tempo Dispensary District.—Medical Officer. Salary £100 per annum, and £14 per annum as Medical Officer of Health, together with the usual Registration and Vaccination Fees. Applications to Richey Wilson, Clerk of the Union. (See advt.)

House of Recovery and Fever Hospital.—Junior Assistant Medical Officer. Salary £50 per annum, and board. Immediate application to the Medical Superintendent. (See advt.)

Horton Infirmary, Banbury.—House Surgeon. Salary £100 per annum, with board and residence in the Infirmary. Applications to E. Lamley Fisher, Hon. Secretary, Horton Infirmary, Banbury.

Johannesburg Hospital, Johannesburg, South Africa.—Non-Resident X-Ray Medical Officer. Salary £750 per annum, with the right of private practice. Applications to Dr. Lewis Jones, 143 Harley Street, London, W.

Kent County Asylum, Chartham, near Canterbury.—Third Junior Assistant Medical Officer. Salary £220 per annum, with furnished apartments, lighting, heating, attendance, laundry, milk, and garden produce. Applications to Medical Superintendent.

Lincoln Mental Hospital, The Lawn, Lincoln.—Assistant Medical Officer. Salary £150 per annum, with board, etc. Applications to Dr. Russell, Medical Superintendent.

Whittingham County Asylum, Preston, Lancs.—Assistant Medical Officer. Salary £200 per annum, with board, furnished apartments, and washing. Applications to the Medical Superintendent.

Births.

ANDREW.—On July 4th, at Lynton, Leiston, Suffolk, the wife of H. T. Andrew, M.B., of a son.

BENTALL.—On July 10th, at 13 Roe Lane, Southport, to Dr. and Mrs. Bentall—a son.

FOSTER-BARHAM.—On July 5th, at Horton Lane, Epsom, the wife of G. Forster-Barham, M.D., of a daughter

JEUDWINE.—On July 9th, at 7 Brooklands, Filey, the wife of Capt. W. W. Jeudwine, I.M.S., of a son.

MCLEAN.—On July 12th, at Bay View, Rushbrooke, Co. Cork, Ireland, the wife of W. McLean, M.R.C.S., L.R.C.P.Lond., Medical Inspector Board of Trade, of a daughter.

PRINGLE.—On July 13th, at 195 Croydon Road, Anerley, the wife of Ernst George Pringle, M.D., of a daughter.

Marriages.

DIXON—ALLEN.—On July 5th, at Christ Church, Sutton, Surrey, Robert Halstead Dixon, M.B.Lond., of Ealing, son of Robert Dixon, of Truro, to Edith Kate, only daughter of the late George Allen and of Mrs. Allen, Farringford, Sutton, Surrey.

HALL—MEIN.—On July 10th, at Jesmond Church, Newcastle-on-Tyne, George Hall, M.D., B.Sc., M.R.C.P., 9 Ellison Place, only son of Mr. and Mrs. M. Stokoe Hall, to Margaret, elder daughter of Mr. N. Mein and the late Mrs. Mein.

Deaths.

JOHNSON.—On July 8th, after a long illness, at 57 Talbot Road, Bayswater, W., William Alfred Johnson, M.D., L.R.C.P., L.S.A.Lond., member of the General Council of St. Andrews, youngest son of the late Edward Johnson, M.D., of Umberslade Hall, Warwickshire, aged 84 years.

MABERLY.—On July 6th, at Kingsway, Burnham, Somerset, G. F. Maberley, M.R.C.S., in his 90th year.

MCCASKIE.—On July 7th, at Southport, Norman McCaskie, M.D., aged 64.

OPERATIONS—METROPOLITAN HOSPITALS.

WEDNESDAY.—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas's (2 p.m., London (2 p.m.), King's College (2 p.m.), St. George's (Ophthalmic, 1 p.m.), St. Mary's (2 p.m.), National Orthopædic (10 a.m.), St. Peter's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Gt Ormond Street, (9.30 a.m.), Gt. Northern Central (2.30 p.m.), Westminster (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Cancer (2 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

THURSDAY.—St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), University College 2 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), London (2 p.m.), King's College (2 p.m.), Middlesex (1.30 p.m.), St. Mary's (2.30 p.m.), Soho Square (2 p.m.), North-West London (2 p.m.), Chelsea (2 p.m.), Great Northern Central (Gynæcological, 2.30 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), St. Mark's (2 p.m.), Samaritan 9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

FRIDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), King's College (2 p.m.), St. Mary's (2 p.m.), Ophthalmic (10 a.m.), Cancer (2 p.m.), Chelsea (2 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), City Orthopædic (2.30 p.m.), Soho Square (2 p.m.).

SATURDAY.—Royal Free (9 a.m.), London (2 p.m.), Middlesex (1.30 p.m.), St. Thomas's (2 p.m.), University College (9.15 a.m.), Charing Cross (2 p.m.), St George's (1 p.m.), St. Mary's (1 p.m.) Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

MONDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), St. George's (2 p.m.), St. Mary's (2.35 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), Chelsea (2 p.m.) Samaritan (Gynæcological, by Physicians, 2 p.m.), Soho Square (2 p.m.), Royal Orthopædic (2 p.m.), City Orthopædic (4 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Royal Free (2 p.m.), Guy's (1.30 p.m.).

TUESDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), West London (2.30 p.m.), University College (2 p.m.), St. George's (1 p.m.), St. Mary's (1 p.m.), St. Mark's (2.30 p.m.), Cancer (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Royal Ear (3 p.m.), Samaritan (9.30 a.m. and 2.30 p.m., Throat, Golden Square (93.0 a.m.), Soho Square (2 p.m.).

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, JULY 23, 1913. No. 4.

NOTES AND COMMENTS.

A Medical Poet Laureate.

MEMBERS of the medical profession have at various times taken a place in the front ranks of art and literature. Poetry is one of the emotional gifts that might well receive stimulation from the intimate contact with the facts of life and character that forms part and parcel of the daily routine of a doctor's existence. As a matter of fact, there have been many poets in our profession, the most distinguished amongst them being Keats. The crown of the laureateship, however, has not hitherto fallen to the lot of any of them, a fact that may be taken to imply not so much that their poetry has fallen short of the true æsthetic standard as that their voices may not have caught the popular and the official ear at the moment when time and circumstance have demanded the filling of a vacant laureateship. Be that as it may, the world of medicine may now boast its Poet Laureate in the person of Mr. Robert Bridges, whose appointment by the King has just been gazetted. He was born in 1844 and educated at Eton and Oxford. Later he studied medicine at St. Bartholomew's and took the degree of M.B.Oxon. in 1874, and the diploma of Fellow of the Royal College of Physicians of London in 1900. He held the posts of Assistant Physician to the Children's Hospital in Great Ormond Street, and of Casualty Physician at St. Bartholomew's. He retired from the practice of his profession in 1882 and devoted himself to poetry. His work, although little known to the public, is held in high esteem by competent judges. His publications include eight poetic dramas, various shorter poems and sonnet sequences, of which the most notable are "The Growth of Love," and "Eros and Psyche," and a masque entitled "Demeter," which has been performed at Oxford. A collection of his works has been recently published.

A Fighting Medical Officer.

THE Medical Officer of Health for Ilford, Dr. Cornelius F. Stovin, in the discharge of his official duties, has brought the sanitary administration of his district prominently before the gaze of the public. He had some personal differences with the Borough Council, and these were at length subjected to the ordeal of a Local Government Board inquiry. From the facts disclosed, it appears that Dr. Stovin presented an annual report to the Council to which he added in its final published form a considerable amount of matter that had not been originally submitted by him. A course of that kind not unnaturally excited a good deal of comment, and is not of the kind that would be commended as an example to other medical officers of health. Fortunately, however, the point seems to have been waived by the Ilford Council, and their differences with Dr. Stovin appear to have been amicably settled. The chief grievance of the latter, so far as can be gathered from the reports of the Government Inquiry, seem to have been certain drainage defects that were not dealt with by the sanitary authority on his representations. All's well that ends well. Dr. Stovin has had the courage of his convictions, he has fought for a sound cause, and his methods, even if somewhat quixotic, have apparently been crowned with success.

A Bogus Medical Practitioner.

LAST week, at Glasgow Assizes, one Richard Harrison was sentenced to twelve months' imprisonment for having given a death certificate purporting to be from a registered medical practitioner, he being unregistered under the Medical Act. Prisoner had acted at Swindon as an unqualified medical assistant to a Dr. A. P. Walters, a name which he assumed at Treforest, when he signed the death certificate on which the criminal charge was based, as "M.R.C.S. and L.R.C.P." From statements made in Court it seems that there were other charges outstanding against the prisoner, who was of drunken habits. It was proved by the police that in 1900 he was at Bromsgrove, afterwards at Aberavon, and finally at Pontypridd in 1905. There was a conviction against him at Maidstone for a similar offence. Such being the case, one may well wonder why the police should permit so notorious an offender to wander from place to place and settle down to his nefarious practice in fresh quarters. The fact of the matter, as it has often been pointed out in these columns, is that the control of quacks and quackery is very much in the hands of the police of the United Kingdom. Given the intention and the requisite driving power they could speedily rid the nation of these undesirable rogues and vagabonds. When the police take action, as they do on rare occasions, it is almost always against some unfortunate medical man who has been unfrocked, or someone who has acted as unqualified medical assistant. The quack who has no shred of medical knowledge or training is infinitely safer than either of the two foregoing offenders from the attentions of the police, no matter how gross his claims or how unbridled his cruelty and rapacity. It is not unlikely that existing laws provide ample machinery for suppression by the police of medical quacks and quackery.

The Wording of Medical Certificates.

IN accordance with the best traditions of the profession, it has been the custom on the part of medical men not to give the name of a disease from which a patient is suffering upon any medical certificate, except that used for death, where it is felt that this would be prejudicial to the patient's interests. It cannot be necessary that employers should always know the exact nature of any malady with which an employee is affected, any more than other private personal details regarding him. The two vital questions are, "Is the illness contagious?" and "Does it incapacitate the employee from work?"—briefly to answer which is all that is required in the majority of cases. To divulge the nature of a disease might be highly detrimental to the worker, and it would be contrary to the established ethics of medical practice. It is satisfactory, therefore, to note that the Lancashire Insurance Committee have recently effected a compromise with medical men on the panels in agreeing to accept the word "illness" on certificates instead of the name of the disease in those cases which the medical attendant considers exceptional. Apart from the ethical aspect of the question, this move will tend towards the prevention of verbal inaccuracy. Medicine is not an exact science, and it is not always possible to make a correct diagnosis upon the first examination of a patient. To compel medical men to state the nature of the disease at once is simply to crush all spirit of scientific investigation and to encourage slip-shod methods. It is to be hoped that the example of the Lancashire Insurance Committee may be copied by other authorities throughout the country.

The Future Site of London University. During the past week the pros and cons of the future site of the University of London have been vigorously discussed. Two sites only seem to have been seriously considered by the Senate. The first is the one at Bloomsbury, near the British Museum. The chief objections seem to be its inadequate size and its huge cost. The other site is that on the south side of the Thames, east of the palatial hall now being built for the London County Council. This situation is warmly advocated by the Council, which, as the educational authority of London, naturally has a considerable voice in the matter, besides which it will have to find some of the purchase money. The crucial objection to the south side of the Thames is its aloofness from the hub of the metropolis. It is to be hoped that the Senate will not come to any hurried decision. There is a third site which appears to have escaped the notice of the *Times* and the other London newspapers in some inexplicable way, namely, that of the Foundling Hospital, which will shortly become vacant, owing to the removal of the children to country quarters. This site is ample in size, it is central in position, and if only the purchase money could be raised London could be put in possession of a home worthy of her academic Alma Mater. It is to be hoped that the advantages of the Foundling Hospital site will be laid before the public and considered by the Senate at least as fully as those of the British Museum and the Embankment.

LEADING ARTICLES.

SUGGESTED REFORMS IN THE BRITISH MEDICAL ASSOCIATION.

In spite of various vicissitudes of fortune, the British Medical Association remains the established centre of organisation of the medical profession. After all said and done, it constitutes our main hope, as it is our chief stimulus for future progress in the consolidation and protection of professional interests, as well as in the furthering of scientific information. Like all human institutions, the Association has its defects, and it is well to recognise that its future strength must to a great extent depend on the candour with which self-criticism and suggestions for reform are examined. In a spirit of entire friendliness, therefore, certain points of policy advanced by what may be termed the advanced wing of the Association may be briefly noticed. The tenour of these proposals may be gathered from the instructions to representatives of the Brighton meeting, which appeared last week on the agenda of the Marylebone Division of the Metropolitan Counties Branch of the Association. The first dealt with a suggested increase of subscription. Many members hold that it was a mistake to increase the original subscription from one guinea to twenty-five shillings, and that any further increase is to be deprecated. What value does a member get for his money? He has a weekly journal of portentous size, but that is surely a self-supporting property to which he is entitled to look for huge profits to the corporate income. He has the privilege of belonging to a branch and of attending the annual meeting, and his general interests are defended by the Council of the Association; there is also the use of a library and central London offices. He does not, however, obtain the advantages of individual protection against the legal complications incident to his profession. The question of the increase of fee opens up the financial aspects of the case, which obviously lie at the root of the whole matter. This is more directly approached in the second item, namely, "the necessity for decreased expenditure." The finance of the Association, in our opinion, requires careful expert inquiry, with a view to increased economy, especially in the conduct of the journal. The latter is a magnificent journalistic property which in private hands would be made to yield a far larger profit than it does under present conditions. The journal, in point of fact, should suffice in itself to sustain the cost of various developments in favour of members. The formation of a new company, which is next raised, suggests the spirit of unrest that has undoubtedly permeated the profession to a large extent during the past few years. Presumably it is proposed to reconstitute the existing company on broader lines rather than to form a brand new corporation. Next comes the resignation of representatives, doubtless an outcome of the Insurance Act disputes. It seems clear that some means of enforcing an automatic resignation is needed when a representative is absolutely out of touch with his constituents. Then the question of a Central Defence Fund is brought forward. That a large reserve of the kind should be in the hands of the Association to meet emergencies is clearly of vital importance. How it is to be raised is a different matter, but we adhere to the question that under economic management the journal of the Association should be able to provide all the necessary funds. The sixth item is "the formation of a trades union." There could hardly be a surer token of the rapid changes that have taken place in the professional attitude with regard to social matters than the deliberate proposal to form a trades union. It apparently registers an advance in a commonsense handling of the economic side of professional life, an aspect that must in the long run be forced remorselessly upon all human enterprises. Dr. F. J. Smith, whose name is now inseparably connected with thorough and enlightened reform, suggests that each division should have power to refer any question to a postal vote within its boundary. Clearly, any proposal that renders representation more direct and more authoritative deserves careful attention. The eighth item is the "reform of the constitution." It is well that this question should be brought forward at Brighton. The recent experiences during the passage of the Insurance legislation have shown the administration of the Association to be cumbrous, slow, and to a large extent irresponsible. It should not be beyond the wit of the Association to frame a constitution under which it would be impossible for administrative control to drift into the hands of a few individuals. In other words, the government of the Association should be democratic, directly representative and responsible to its constituents. The final clause in these "instructions" deals with the inevitable Insurance Act, which need not be considered here. The rest of the items, as readers will recognise, raise matters of vital importance to the present and future welfare of the British Medical Association, and it is to be hoped they will in due time reach a wise and final settlement.

THE PROFESSION IN IRELAND.

The delegates' meeting held last Thursday in the Royal College of Surgeons was, we are glad to say, thoroughly representative. This was the first essential for the foundation of a successful organisation. In the next place, an executive committee was constituted which may prove to be the strongest which has yet acted for the profession. At any rate, it is the most democratic and the most directly representative. To begin with, the over-representation of the two larger associations—the British Medical and the Irish Medical—has been cut down to an equality with that of the various smaller societies and of the universities and medical corporations. Each of these bodies is, in future, to nominate one member of the executive committee. The strongest point of the constitution, however, is the fact that every county area in the country is to send one representative. The larger towns are to have increased representation. This introduction on a large scale of the principle of direct representation will have two good effects. It will increase the sense of responsibility of the members of the committee, and it will give the profession of every district a direct voice in all discussions and decisions. By this means the committee will be in a strong position to gauge professional feeling on every point that arises. It need hardly be said that in the elections and nominations that will take place in the next few weeks, great care will be required. We want not merely strong men, but cool men. The noisiest in a public meeting is not necessarily the wisest. The committee is likely to have more important questions to deliberate on than the Irish profession has ever yet had to face. Men of various qualities and opinions are required, for only so can the general voice of the profession make itself heard. So far, we have not referred to the one weak point in the new constitution—the question of finance. Up to the present, almost the entire expense of organisation has been borne by two bodies—the two larger associations. It is more than doubtful whether either of these can contribute in the future. It is all but certain that the British Medical Association has not the power to do so. Unless, therefore, the members of the profession determine to shoulder the burden themselves, the whole organisation will come down like a house of cards. The sum required is not large. Eight hundred or a thousand a year would be ample. It is extraordinary, however, how careless members of the profession are of their own interests, and unless the matter is taken up determinedly all through the country the fight cannot be carried on.

CURRENT TOPICS.

The Mount Vernon Hospital Staff Resignations.

On Thursday last a telephone message reached the office of the Medical Press and Circular from a firm of solicitors, which was duly received by a junior clerk in the absence of the manager. The senders asked the clerk peremptorily for the name of the writer of the article upon Mount Vernon Hospital in our issue of the 16th. This extraordinary telephonic request coming from a firm of solicitors obviously contemplating a libel action was naturally declined. Later in the day, on being rung up by our manager, the solicitors repeated their demand for the name of the writer, which was again refused with a suggestion that the proper course for a firm of solicitors to pursue under such circumstances was to communicate in writing. On Friday we received a letter from them, saying that their clients, the Committee of Management of Mount Vernon Hospital, considered they had been "grossly outraged" by the article in question, and "that a paper claiming to influence the minds of others should be fair and accurate in the statements which are permitted to be made in its columns." To that letter we sent an immediate reply asking details of any point or points of unfairness in our article, and offering, should we be convinced of any unfair or inaccurate statements, to give publicity to the same in our next issue. The fact that we go to press early in the week was intimated, but in spite of the apparent urgency of the matter in the minds of the solicitors, no answer to our letter had reached us late in the afternoon of Monday, July 21st. A telephone message asking when a reply might be expected was answered by them to the effect that they had nothing to say until they heard further from their clients. In view of the forcible terms of the solicitors' letter, it is somewhat surprising that there should be any delay on the part of the Committee in giving particulars of what is described as a "gross outrage." This brief note is inserted in order that our readers may learn that the management have a version of the staff resignations sufficiently convincing to themselves to warrant the intervention of a firm of solicitors.

Yellow Bacteriology.

The daily Press has again been exerting its influence towards the enlightenment of the public. That the poorest man may not live a day longer without scientific knowledge of some sort or another our morning papers have found room between the fat advertisements of lying cure-alls for a bacterio-statistical paragraph lifted from *Le Matin.* We are told impressively that "a cubic centimetre of the water in which a bronze coin of 10 *centimes* was washed would disclose no fewer than 760,000 bacteria, 3 per cent. of which was mouldiness." This alleged sentence is almost worth reprinting for its plucky disregard of literary conventions, but still more as it is a fair example of the stuff that is doled out to us for our improvement. Apart from the fact that we have no idea of how many cubic centimetres of water were used, and that therefore we cannot say what proportion the 760,000 bacteria mentioned bear to the total intrinsic flora of the French penny, it is doubtful whether these rows of zoetropic zeros convey much to us. The figures are so big it is hard to get a grip of them. The whole game is very futile. An educated Frenchman spending his days in laundering our personal equipment or douching out our naso-pharynx, publishing the results, then asking to be taken seriously, is too much of a good thing. We are quite free from the clutches of the green-eyed monster, even if this is one of the things they do better in France.

Deutschland ueber Alles.

Germans are human. We have looked upon them for so long as a race of iron fists with no velvet glove, as indomitable supermen plodding unswervingly towards a place in the sun, as beings who would attain their appointed goal at any cost unmoved by human frailties, and only amenable to the dictates of science, patriotism, and the police regulations. We were wrong every time, and all the time. They are men like unto ourselves, and liable to carelessness even in matters scientific. The Prussian Minister of the Interior has issued a decree. It starts off with some glitterless generalities about the undesirability of issuing potent poisons to the public in bulk and with no directions. After these wise saws come modern instances of how the German club doctor manages his dispensing. He has issued 25 grams of salicylate of sodium, with directions that this be divided into twenty-five doses, and one half of these self-divided quantities be taken occasionally. "As much as will go on the point of a knife" is a frequent direction for the internal administration of drugs, and one man ordered a tablet of corrosive sublimate to be dissolved in "a beer-bottle of vinegar." There is no evidence that these slipshod methods actually resulted in definite harm to anyone, but it is certainly right that they should be discouraged. And it may be a comfort to some of us to see that such careless ways and slackness are not a monopoly of our own country.

The Nursery School.

A problem of no small magnitude is that of the care of young children under the school age among the poorer classes. The homes of many such infants are anything but rearing grounds for healthy children, who would undoubtedly be much better if they were cared for in an institution—if only for a few hours daily. The question was discussed in the Section of Hygiene of Infancy and Child-Study at the recent Congress of the Royal Sanitary Institute at Exeter, in a paper by Dr. F. H. Stirk, School Medical Officer, Exeter. The ordinary day nursery does not always fulfil the functions that might be expected of it, since any trained supervision therein is too often intermittent rather than continuous. The ideal plan would appear to be the extension of the work of the health visitor, infant consultations, etc., up to the end of the second year, when the child could be admitted to the nursery school. Here it would be attended with others up to the age of five, and the school would therefore include the present babies' classes of air infant schools. In poor districts the gain to the community would be enormous, for a good healthy foundation would be laid before the school age commences. The staff should consist of teachers as for infant classes, a woman to tend the children and wash them when necessary, and the school nurse would make daily visits with a view to the early detection of disease. The school medical officer would attend when required by the school nurse. From the financial standpoint, such an enterprise might prove a little more costly than the existing infant schools, but this could be met in part by a capitation grant from the Board on the basis of that for older children. The experiment is one which should commend itself seriously to the notice of all local authorities.

The National Association for the Prevention of Consumption.

Two days before the International Congress of Medicine opens in London, the National Association for the Prevention of Consumption and other Forms of Tuberculosis will hold its Fifth Annual Conference in the Central Hall, Westminster. The opening address will be delivered by the Right Hon. H. H. Asquith, M.P. On August 4th Dr. H. W. G. Mackenzie will introduce the subject of tuberculin treatment in a general survey, and papers on the nature of tuberculin—its preparation, varieties, and underlying pathological principles—will be read by Professor G. Sims Woodhead, of Cambridge, and Professor Lydia Rabinowitsch-Kempner, of Berlin. Professor Beraneck, of Neuchatel, will read a paper on the *rationale* of the use of tuberculin: its possibilities and limitations; and the therapeutic value of tuberculin and the principles of dosage will be dealt with by Professor Sahli, of Berne, and Dr. Nathan Raw, of Liverpool. The range of application of tuberculin will be discussed by Professor Adami, of Montreal, Sir James Kingston Fowler, Sir St. Clair Thomson, Sir R. W. Philip, Dr. Noel D. Bardswell, Dr. Clive Riviere, and others. On August 5th there will be a public discussion on the need for the co-ordination of anti-tuberculosis measures. The opening address will be delivered by Sir R. W. Philip and the following delegates have promised to take part:—Professor Adami (Canada). Dr. Hermann Biggs and Professor W. C. White (United States), Professor Pannwitz (Germany), Dr. Rist (France), Professor Saugmann (Denmark), Professors Tamburini and Signorelli (Italy), and Dr. von Unterberger (Russia). A conversazione will be held on the evening of Monday, August 4th, at which Dr. Rollier (Leysin) will give a cinematograph demonstration on the cure of surgical tuberculosis by direct sunlight. A film ("The Fight against Consumption"), illustrating the working of a complete co-ordinated scheme for dealing with consumption will also be shown. The ensuing week is pre-eminently one of congresses, so that those practitioners who are up in London may find it advantageous to attend as many meetings as possible, especially as we understand that tickets of admission are being sent to all medical practitioners in the Metropolis.

Leprosy in the Light of Modern Research.

Many problems concerning the ætiology of leprosy have been attacked with fresh vigour during the past few years, especially from the bacteriological and prophylactic aspects. Our contemporary, the *South African Medical Record*, entering into the spirit of modern methods, has recently issued a series of three special numbers devoted to leprosy, the writers dealing with the subject primarily from the standpoint of South Africa, but at the same time generally in the light of modern research. Dr. H. Bayon, the Research Bacteriologist in Leprosy to the Government of the Union of South Africa, contributes a most interesting article entitled "A Critical Review of Recent Experimental Leprosy Research" Among the conclusions at which he arrives are the following: That Kedrowsky's culture is true leprosy; that the disease can, in certain circumstances, be transmitted to animals, the most suitable apparently being the rabbit, rat and mouse; and that leprosy is a contagious disease. He regards this last point as established "because it is a disease due to a definite bacterium; because the great majority of cases originate in countries where leprosy is relatively common; where the disease has developed in individuals who had never left a leprosy-free country, the intimate contact with lepers, who, in their turn, had contracted the disease abroad, is proven; and because in the countries where leprosy has been re-introduced in modern times, the infection spreads concentrically from the first imported cases." In an article on "The Administrative Side of the Leprosy Question," Dr. C. F. K. Murray, the Chairman of the Leprosy Commission in 1894, advocates a modification in the present system of segregation, advising the establishment of leper settlements or villages to admit of family life, the granting of enough land to allow those able to work to do so, the establishment of one or more central leper hospitals to which all the more feeble should be sent for treatment, and the impressing upon the sick of the value of the settlement from the standpoint of cure.

PERSONAL.

H.R.H. Princess Louise (Duchess of Argyll) will open the completed building of the Hospital for Epilepsy and Paralysis, Maida Vale, on Friday next.

The Duke and Duchess of Norfolk opened the new premises of the Norfolk and Norwich Hospital last week.

The Duchess of Albany opened the new buildings of the Central London Ophthalmic Hospital last week.

Dr. Albert Lindow, of Plumstead, has been placed on the Commission of the Peace for the County of London.

Mr. John George Fenwick, late of Bournemouth, has bequeathed £50,000, free of duty, to the Newcastle Royal Infirmary.

Dr. William Dyson, M.D.Vict., has been appointed Honorary Special Lecturer in Dermatology in the University of Manchester.

Dr. Robert Bridges, M.A., M.B.Oxon., F.R.C.P., formerly attached to the staffs of St. Bartholomew's and the Great Ormond Street Children's Hospitals, has been appointed Poet Laureate.

Dr. A. J. Clark, M.B.Cantab, M.R.C.P.Lond., has been appointed Lecturer in Pharmacology at Guy's Hospital Medical School.

Mr. Kenelm H. Digby, M.B., B.S., F.R.C.S., has been appointed Professor of Anatomy in the New University of Hong Kong.

Dr. E. N. Cunliffe, M.D.Vict., M.R.C.P.Lond., has been appointed Lecturer in Clinical Medicine in the University of Manchester.

Dr. David Hunter, M.A., M.B.Cantab., has been appointed Medical Superintendent of the Coppice Mental Hospital, Nottingham.

Mr. L. E. Barrington-Ward, Ch.M., F.R.C.S.Edin. and Eng., has been awarded the Chiene Medal in Surgery in the University of Edinburgh.

Dr. T. Buzzard, M.D., F.R.C.P., has been appointed by the Senate of the University of London a Governor of the Westminster Hospital Medical School.

Mr. P. L. Watkin Williams, F.R.C.S.Edin., M.R.C.S., L.R.C.P.Lond., has been appointed Consulting Surgeon to the Bridgewater Workhouse Infirmary.

Dr. James Galloway, M.A., M.D.Aberd., F.R.C.P.Lond., has been appointed Consulting Physician for Skin Diseases to the Metropolitan Asylums Board.

At the last meeting of the Maidstone Town Council Dr. Charles Pye Oliver, M.O.H., was publicly congratulated by the mayor on his recent appointment as an Honorary Physician to H.M. the King.

Dr. G. C. McK. Mathison, M.D.(Melb.), has been awarded the D.Sc. degree in Physiology of the University of London, for a thesis entitled "The Action of Asphyxia upon Nerve Centres," and other papers.

Our readers will sympathise with Dr. J. L. Livingstone, of Hursley, near Winchester, in the sad death of his seventeen-year-old son, who fell from a tower of Bodiham Castle, Sussex, to the ground, and was instantly killed.

Dr. John Gutch, of Ipswich, was the recipient the other day of a handsome presentation at the annual meeting of the East Anglian branch of the British Medical Association, in recognition of his valuable services as secretary for the South Suffolk Division of the Association for many years past.

Dr. James Ritchie, M.A., M.D., B.Sc., F.R.C.P.Edin., Superintendent of the Laboratory of the Royal College of Physicians of Edinburgh, and well known as the joint author of Muir and Ritchie's "Manual of Bacteriology," has been appointed to the new Chair of Bacteriology in the University of Edinburgh, instituted under the bequest of Mr. Robert Irvine, Royston, Granton.

Dr. H. F. Hayes Newington, for twenty years Treasurer of the Medico-Psychological Association of Great Britain and Ireland, and a Past President, was presented with his portrait in oils and an address last week upon the occasion of the 40th anniversary of his connection with the Association. The Committee who signed the document included a number of the Association's past Presidents.

Capt. P. J. Marett, R.A.M.C., who has already published valuable papers upon sand-fly fever, has been selected to undertake a research into the nature of the virus of this disease, in addition to his military duties at Malta. Captain Marett will have the title of Beit Memorial Research Fellow, inasmuch as the research is being assisted by the trustees of the Beit Memorial Fellowships, upon the advice of the advisory board.

CLINICAL LECTURE
ON
REFLEXES AND THEIR SIGNIFICANCE. (*a*)

By FREDERICK S. PALMER, M.D., F.R.C.P.Lond.,

Physician to the West End Hospital for Diseases of the Nervous System.

FROM the clinical standpoint, the study of reflexes is indispensable in all neurological cases. It is of paramount diagnostic and localising importance. By a careful observation of these tests valuable evidence is obtained of the condition of the spinal centres, and of the pathways of conduction above and below them.

As the grey matter in every segment of the spinal cord is known to contain centres for certain muscle groups, and reflex movements, a knowledge of these signs, the various segments to which they belong, together with their anatomical and other relations constitutes the basis of spinal localisation. In the physiological sense of the term a reflex is briefly defined as "the result of peripheral excitation," or, in other words, the involuntary response to a stimulus applied to the surface—mucous, cutaneous, or tendinous. The time usually occupied in the reaction is estimated at about one-tenth of a second. Normal reflex activity depends on the integrity of the reflex-arc, and its proper connections with other centres situated at higher levels. If any one of these structures be irritated or destroyed, irregularities of reflex-action occur. The reflex-arc is constructed of an afferent, or sensory nerve, an intermediate centre (spinal cord or medulla), and an efferent or motor nerve. Excitation of the centripetal nerves reaches the centre by the posterior roots, from whence the motor response is transmitted along the centrifugal route. All lesions of the reflex-arc which diminish the function of conduction either decrease or abolish the reflex movement; but when the spinal centres are abnormally irritated, and when they are incompletely cut off from the controlling influence of the cerebral centres, the reflexes are increased. Total destruction of communication between the centres at different levels, whether it be caused by injury or disease, results in abolition of the deep reflexes below the seat of the lesion. Before discussing the various methods of eliciting reflex-action, it should be borne in mind that in certain instances, the movement may be inhibited by voluntary effort, and in some functional diseases, notably neurasthenia and hysteria, the reflexes are very frequently exaggerated. In order to arrive at an accurate conclusion of the results of these tests, it is essential to obtain complete relaxation of the muscles, and, if possible, to secure the intelligent cooperation of the patient. Several observations are sometimes necessary. Three groups of reflexes are distinguished:—

(1) Superficial—cutaneous or mucous.
(2) Deep—muscular or tendinous.
(3) Organic—or visceral.

SUPERFICIAL.

In this group are included the cranial reflexes, such as contraction of the pupil to light, dilatation of the pupil on irritating the skin of the neck, contraction of the palate on tickling the fauces, sneezing and lachrymation from irritation of the nasal mucosa, etc.

The cutaneous reflexes vary in activity even in normal individuals. Usually they are most marked in children, and they are more easily obtained in women than in men. They consist of more or less rapid muscular contractions in or near the part stimulated, but if the excitation be excessive, the contractions may spread to neighbouring muscle groups, or invade others at a distance. When present, the reflexes demonstrate the integrity of the reflex-arc at the level which is being tested, or through which such impulses are travelling. In organic cerebral hemiplegia the superficial reflexes, with the exception of the abnormal type of plantar reaction, are at first commonly diminished or lost on the affected side, but subsequently they are increased.

The most important normal cutaneous reflexes with the spinal segments to which they belong are:

Scapular.—Contraction of the scapular muscles on stroking the skin between the scapulæ 5th cervical to 1st dorsal.

Epigastric.—Contraction of the upper fibres of the rectus with dimpling of the epigastrium on the side irritated, on stroking the skin downwards from the nipple. 4th to 7th dorsal.

Abdominal (Rosenbach's sign).—Contraction of the abdominal muscles with drawing of the umbilicus to the side stimulated, on stroking the skin in a downward direction from the costal arch, or on scratching the skin over the outer edge of the rectus. 9th and 10th dorsal.

Absence of the reflex is very often an early and fairly reliable sign in disseminated sclerosis. It is also frequently lost in some actute abdominal diseases, and said to be exaggerated in pachymeningitis and early tabes.

Cremasteric.—Ascension of the testicle on stroking the skin over the inner side of the thigh, or by making pressure over the sartorious muscle. 1st and 2nd lumbar.

The reflex is sometimes diminished, or may be absent in elderly men, and exaggerated on the affected side in some cases of sciatica.

Bulbo-cavernous.—Contraction or twitching of the bulbous urethra, felt by a finger placed behind the scrotum, on pinching or pricking the dorsum of the glans penis. 3rd or 4th sacral. Loss of the reflex is common in tabes.

Gluteal.—Contraction of the gluteal muscles on stroking the skin of the buttock. 4th and 5th lumbar.

Anal.—Contraction of the sphincter ani on pricking the perianal cutaneous surface. 5th sacral and coccygeal.

Plantar.—Flexion of the toes, most marked in the four outer ones, on slight stimulation of the sole of the foot. The movement is accompanied

---

(*a*) Clinical lecture delivered at the West End Hospital on May 28th, 1913.

with, or preceded by, contraction of the tensor fasciæ femoris, and if at all pronounced, by drawing up of the leg and thigh. 5th lumbar to 2nd sacral.

Careful observation of the test is of the utmost importance. The stimulation should be gentle, just sufficient to provoke a slight response and no more. In children under three years of age, or who are unable to walk, the normal reaction is extension of the toes.

The most convenient method of eliciting the reflex is to place the limb to be tested at rest, rotated on its outer side, flexed at the hip and knee, then gently scratch the outer side of the sole with a pencil, and watch the first movement of the toes, particularly the hallux.

Abnormal Cutaneous Reflexes.

Plantar (Babinski's phenomenon).—Extension of the great toe on gentle stimulation of the sole of the foot with or without a fan-shaped extension of the other toes (*phénomène d'éventail*). The response is less rapid in appearance than the normal movement of flexion.

Oppenheim's Reflex.—Extension of the hallux obtained by making firm pressure along the inner edge of the tibia from above downwards.

Paradoxical Flexor Reflex (Gordon's sign).—Extension of the great toe brought about by squeezing, or making firm pressure on the deep calf muscles.

Malleolar Reflex (Chaddock's sign).—Extensor movement of the hallux on scratching the skin over the outer malleolus from the heel inwards.

Persistent extension of the great toe obtained by any of these methods is a manifestation of some defect in the pyramidal system, rarely, if ever, seen in health. Gordon claims for the paradoxical flexor response that " it is also present in slight lesions, or irritation of the motor tract, and motor centres," and may be elicited in some cases long before the Babinski plan gives a definite result. I have made a great many observations of the test during the last four years, and my experience is that I have been much more successful in eliciting the response by gentle irritation of the outer side of the sole than by any other method. The same may be said of Oppenheim's and Chaddock's signs.

Normal Deep Reflexes.

Although these reactions are commonly called tendon reflexes, the description is not strictly correct, since they may be provoked by concussion of the periosteum and muscle, as well as by the tendon. Like the normal superficial reflexes, they may be increased, decreased, or abolished. As a rule, they are increased in spastic paralysis and decreased in atrophic cases. There appears to be considerable doubt whether they can be regarded as true examples of spinal reflexes, or merely indications of the myotatic irritability of muscular tonus. For clinical purposes it is sufficient to say, their presence implies that the reflex-arc at the level under investigation is intact.

The most important of the deep reflexes and their segmental levels are :—

Arm-jerk.—(*a*) Contraction of the biceps, when the arm is semi-flexed, on tapping the tendon at the bend of the elbow. 5th and 6th cervical, flexion movement.

(*b*) Contraction of the triceps, when the arm is semi-flexed and the hand supported by the observer, on striking the tendon or muscle at the back of the elbow. 7th cervical, 1st dorsal, extension movement.

Wrist-jerk.—Contraction of the supinator longus, when the elbow is flexed, and the patient's hand supported, on tapping the forearm about the styloid process of the radius. 6th to 8th cervical. Flexion movement.

The reflex is often increased in neurasthenia and disseminated sclerosis, and sometimes diminished in tabes.

Knee-jerk (Westphal's sign).—Contraction of the quadriceps extensor, particularly of the vastus internus, with forward movement of the foot and leg, when the flexors of the knee are relaxed, on sharply striking the ligamentum patellæ. 3rd and 4th lumbar.

The ordinary plan of eliciting the reflex is to ask the patient to cross one knee over the other, and this is in most cases sufficient ; but in stout people, who often experience difficulty in placing one lower limb across that of the opposite side, and also in some nervous persons, who are unable to relax their hamstring muscles by this method, recourse must be had to other measures, these are :

A.—The observer passes one arm beneath the hamstring muscles of the leg to be tested, and grasps the opposite knee with his hand, so that the knee rests upon his arm, and the foot is slightly raised from the floor when the patella tendon is struck.

B.—Place the patient on a firm elevated seat with its edge in contact with the hollow of his knee, and his feet not touching the ground, when the slight blow is delivered.

C.—In the recumbent position with his legs extended, the observer draws the patella slightly downwards, places one of his fingers across its upper border, and strikes the finger with a percussion hammer.

D.—Make the patient lie on a couch with the limb to be examined rotated on its outer side, and flexed at the hip and knee when the tendon is tapped.

Reinforcement.

If none of these plans succeed in eliciting a response, the method called reinforcement must be tried. The object in view is to obtain more complete relaxation of the knee flexors by diverting the patient's thoughts from the test, and fixing his attention elsewhere. The measure is useful in increasing the energy of a feeble jerk, but it has no appreciable influence over a reflex which is absent from pathological causes. There are two methods of reinforcement.

Jendrassik's.—The patient seated in a chair with his eyes fixed on the ceiling and his terminal phalanges interlocked on their palmar surfaces, is told to pull strongly with both arms when the tendon is struck.

Laufenauer's.—When the patient is seated with both feet resting on the floor, a little in advance of his knees, he is directed to squeeze the observer's arm when he grasps the quadriceps extensor with one hand, and strikes the tendon with the other.

The knee-jerks on account of their significance and accessibility are probably more frequently tested than any other of the deep reflexes. Not for one moment would I question the value of the evidence thus obtained. Their absence is always highly suspicious of some involvement of the nervous system, central or peripheral, but I feel bound to say that I dissent from the assertion made in nearly every text-book on medicine and by nearly every author who has written on diseases of the nervous system, that loss of the knee-jerks is always pathological. For some years I have devoted a good deal of attention to the subject, and in the out-patients' department of this hospital I have in a few cases failed to elicit the reflex when I have been unable to discover any other definite symptoms of organic nervous disease. I do not attach so much importance to that, because in dealing with numbers in a limited time, it is probable that I did not exhaust all the methods of elicitation, or in a necessarily hurried examination I may have overlooked other objective symptoms; but let me quote two cases from my private notes, about which I feel tolerably sure.

The first is a lady, 56 years of age, unmarried, who has been coming to see me at long intervals for the last 3½ years. Her complaints, chiefly gastric, are I believe entirely functional. At her first visit I tested her knee-jerks and failed to obtain any response. On each subsequent occasion I have repeated the experiment in a different way with precisely the same results. She is quite as concerned as I am about the absence of her knee-jerks, so I cannot imagine she tries to inhibit the reaction. Her pupils are equal, respond briskly to light and accommodation, and her gait is perfectly normal. She is spare and active, and there is no trace of rombergism. From what I know of her character and antecedents, I consider it most unlikely that she ever had specific disease, or has been addicted to alcohol. If she has any organic trouble I am unable to discover it, and the development is very slow, for I think she is in better general health now than when I first made her acquaintance.

The second is that of a medical friend, who called to see me a few evenings ago, and has given me permission to make use of the note. In the course of conversation he told me he had no knee-jerks, and had known that fact for many years. At his suggestion, I tested the statement by every method I could think of at the time; but, like all my predecessors who had examined him, with a negative result. He is a man of good professional standing, whom I have known, and sat next to at committee meetings for the last eight years. I am glad to add that so far as I know, he appears to enjoy excellent health in spite of his absent knee-jerks, and he volunteered the remark that he never had syphilis. From these two examples, and others I can recall, I am convinced that some modification of the statement contained in books is desirable, if not actually necessary. Absence of the reflex is, however, so rarely met with in healthy people that when it occurs either bilaterally or still more significant on one side only, it would make me keenly on the look-out for other signs of organic disease, or developments in the same direction.

The knee-jerks are, or may be, lost in many morbid nervous conditions including tabes, taboparesis Friedreich's ataxia, neuritis, complete transverse myelitis, acute anterior polio-myelitis, progressive muscular atrophy, amyotrophic lateral sclerosis, Landry's paralysis, syringomyelia, the later stages of subacute combined sclerosis, some intracranial tumours with pressure, deep coma, pneumonia, and temporarily in family periodic paralysis and after attacks of epilepsy.

Increase of the reflex occurs in organic diseases of the pyramidal tract without complete break of continuity, in lateral and insular sclerosis, dorsal and cervical myelitis, the early stages of subacute combined sclerosis, tetanus, strychnia poisoning, and in some functional disorders.

Ankle-jerk.—Contraction of the calf muscles when the leg and ankle are flexed, on tapping the Achilles tendon, first and second sacral, extension movement. The most convenient plan of testing the reaction is to make the patient kneel on a chair with his feet beyond its edge.

The reflex is often abolished before the knee-jerk in tabes, and on the affected side in many cases of sciatica.

ABNORMAL DEEP REFLEXES.

Ankle-clonus.—Sustained uniform to and fro movements of the ankle (alternate flexion and extension) at the rate of from 6 to 9 a second, when the knee is flexed, and the observer abruptly flexes the foot, supporting the knee with his other hand.

A spurious form of ankle-clonus is not infrequently seen in functional disease (hysteria) but it is never sustained, nor is it associated with an extensor plantar reflex. It consists of a few vibratory movements when the test is first applied, and passes off quickly.

Jaw-jerk (Mandibular reflex).—Contraction of the masseter and temporal muscles, sometimes accompanied by closure of the eyelids, on tapping a finger placed horizontally across the chin, or on striking a paper knife laid on the lower incisors, when the mouth is partially open.

The reflex is said to be usually absent in health, but from numerous tests made in the wards and out-patients' room, I have noticed a movement strongly resembling a jaw-jerk in some cases of neurasthenia and hysteria.

Contra-lateral movement.—Extension of the leg with adduction of the opposite limb on striking the patella tendon when the patient is in the recumbent position and his knees are semi-flexed.

Paradoxical contraction.—Tonic persistent contraction of the anterior tibial muscles when the foot is gently flexed upon the leg and the muscles are suddenly approximated.

The reflex is rarely obtained and is usually associated with a spastic condition of the lower limbs.

The abnormal deep reflexes with the exception of the jaw-jerk, of the value of which, as a sign of organic disease, I am by no means satisfied, may be looked upon as manifestations of an involvement of the nervous system.

ORGANIC REFLEXES.

The chief organic reflexes of clinical interest are those of the bladder, rectum and pupil. In health, evacuation of the contents of the viscera is performed by contraction of their own muscular fibres (probably in some cases assisted by the efforts of the diaphragm and abdominal muscles), and relaxation of the sphincters which guard their orifices. Normally the sphincters are maintained in a state of tonic contraction, relaxed only during the acts of micturition and defæcation. Both these functions are to a great extent under the influence of the will. The signal for action is given by the sensory nerves, conducted to the brain, and the impulse proceeds along the motor pathway. The centres concerned in micturition and defæcation are three in number—cerebral, spinal, and sympathetic. The highest are located in the cortex, corpus striatum and optic thalamus, the spinal are contained in the second sacral segment, and those for the lowest levels are situated in the hæmorrhoidal and hypogastric plexuses. Any pathological condition of the centres or their connecting links produces disorders of reflex-action, incontinence or retention of urine, diarrhœa, or constipation. Examination of the sphincters in such cases gives us important information concerning the seat of the lesion.

Sphincters.—The state of the sphincter vesicæ is ascertained by passing a sound along the urethra, and noting the degree of resistance encountered.

The sphincter ani is tested by digital examination, and inspection of the anus.

When the sphincters are permanently relaxed from destruction of their centres, as, for instance, in myelitis of the lower end of the spinal cord, there is a continuous escape of urine and fæces; but if the break occurs above the centres and it is complete, there would be at first retention followed by intermittent incontinence, and there may be constipation—the voluntary cerebral influence is suspended. When the bladder is full, the sphincters are relaxed reflexly without the patient having any power to hold back his urine, and it may even be discharged without his knowledge.

If the sphincters remain intact, the bladder may become enormously distended, relief taking place from what is called overflow incontinence. Over-distension of the bladder leads in time to paralysis of the detrusor, the viscus is never emptied, residual urine collects, decomposes, sets up cystitis, and the other evils which follow in the upper urinary organs.

True dribbling of urine (incontinenza veri) is frequently noticed in tabes, from anæsthesia of the bladder, or possibly, from degenerative changes in the sensory part of the reflex-arc.

In tabes, and also in disseminated sclerosis, the urinary disorder may take the form of hesitating or precipitate micturition. Expulsion of the contents of the rectum is most probably influenced by a similar mechanism, incontinentia alvi occurs when the sphincters are paralysed, but the discharge of fæces depends to a considerable extent upon the consistency of the stools, and the efforts of the abdominal muscles.

In the absence of other morbid conditions not of nervous origin, incontinence of the sphincters nearly always means organic central disease, but there is no doubt that it may occur in hysterical affections. About five years ago I saw at a nursing home in one of the suburbs, a young lady, 23 years of age, who was suffering from paresis of the lower limbs with incontinence of urine. She was very emotional—alternately sobbing and laughing. All her cranial nerves and reflexes, with the exception of the pharyngeal, which did not respond, were perfectly normal. She could flex and extend her legs freely in bed, but said she could not raise her heels. She was well nourished, and although she had been in bed some little time, I could not detect any signs of muscular atrophy. Percussion over the pubes convinced me there was no distension of the bladder. After some coaxing I persuaded her to try to get up. The nurse placed her feet on the floor, but when she attempted the erect position, her knees immediately gave way (astasia abasia) and she fell, not on the ground, but very skilfully across the bed. A few applications of the wire brush down the spine arrested the incontinence; in a fortnght I heard she was walking about the room and shortly afterwards left the home apparently cured.

Pupil-Reflex.

The pupillary reflexes are those of light and accommodation.

Light.—If the patient be placed opposite a good light and both his eyes are completely covered by the observer's hands, under normal conditions, when one hand is suddenly withdrawn, the iris is seen to contract at once and decidedly. Wernicki's pupil, or as it is more frequently called the hemiopic pupillary reaction, is a test employed in some cases of hemianopia. A ray of light is thrown on to the blind side of the visual field.

Absence of the reflex indicates a lesion in the optic pathway behind the chiasma between it, and including the quadrigeminal bodies.

Accommodation.—This is easily tested by asking the patient to look first at a distant object, and then at something quite near to him; the eyes must necessarily accommodate to enable him to see it. The centres for the pupil-reflex are the third cranial nerve, the ciliary ganglion and the second dorsal.

Abolition of the light reflex occurs in paralysis of the third nerve, disease of the ciliary ganglion and in advanced optic atrophy. The reflex may be modified or not obtained under certain toxic conditions, such as belladonna or opium. Absence of the ordinary light reflex with preservation of accommodation, the Argyll-Robertson pupil is one of the earliest and most valuable tests of tabes, and general paralysis. It has been noted in nearly eighty per cent. of the cases. It may be unilateral or bilateral, but the presence of a sluggish or normal light reaction does not exclude these diseases, nor does an active knee-jerk.

The opposite of the Argyll-Robertson pupil, loss of convergence with preservation of the light-reflex, is seen in diphtheritic neuritis; paralysis of the palate with regurgitation of liquids, nasal intonation, and the other symptoms of diphtheria would, however, make the diagnosis clear.

Summary.

If we ask ourselves the question what help does the study of reflexes give us in the diagnosis of nervous diseases apart from the important evidence they supply in localisation, I think it may be said:

1.—That the Argyll-Robertson pupil, Wernicki's sign, true sustained ankle-clonus, a persistent extensor type of plantar reflex, the contra-lateral movement, and paradoxical contraction are valuable objective signs of organic nervous disease.

2.—Loss of all reflexes in any particular area points to pathological causes.

3.—Abolition of the knee or ankle-jerks and sphincteric incontinence is strongly presumptive of central or peripheral nervous disease.

4.—Increase in the normal jerks without other objective symptoms is suggestive of neurasthenia.

5.—Absence of the palate and plantar reflexes is in favour of hysteria.

ORIGINAL PAPERS.

THE MEDICAL TREATMENT OF PHLEBITIS.

By H. VAQUEZ, M.D.

Professor at the Faculty of Medicine of Paris, Physician to the Paris Hospitals.

[SPECIALLY REPORTED FOR THIS JOURNAL]

Speaking generally, phlebitis that has been diagnosed is phlebitis that can be cured, provided, of course, that we are dealing with docile patients who grasp the importance of every detail of the treatment During the acute stage the patient must be kept perfectly quiet and motionless, with the head low on a rather hard mattress. He should be absolutely forbidden to sit up or make any attempt to flex the thighs on the trunk, since this movement kinks the veins and may detach an embolus

If the phlebitis be limited to the leg, the latter may be placed in a gutter splint, but should the inflammation extend higher than this, a splint is inapplicable, because it would bruise the sacral and gluteal regions In this case it will suffice to wrap the limb in cotton and fix it by means of broad linen bands which are attached to the mattress with safety pins and are passed round the leg, knee and thigh. It is well to fix also a broad band over the chest to prevent involuntary movements while asleep.

Whenever possible it is preferable to employ a mechanical bed, which greatly facilitates the nurse's duties, indeed it is practically indispensable in cases of double phlebitis, especially as it lessens the irksomeness of immobility.

In any case we must take care that the heel is well supported, not too much raised yet raised enough, in order to avoid the bruising of the heel that would otherwise ensue. The foot should not be in extension but at a right angle and fixed in that position with bandages. The patient's comfort depends on these little attentions.

Medicinally we are justified in relieving the pain by morphine injections at bedtime.

Of local applications some are permissible, while others should on no account be employed. The common practice of applying compresses steeped in a solution of sal ammoniac is simply detestable, because with the idea of setting up counter-irritation we run the risk of causing disastrous effects. The strong solution runs down the leg and collects at the most dependent parts of the limb, macerating the skin and paving the way to sloughing, which may take months to heal. What may be usefully applied is belladonna pigment or belladonna and opium ointment.

After five or six days of the painful stage we must proceed to employ resolutive measures. For three or four hours daily the limb is wrapped in thick hot moist dressings which have the same effect as a poultice, these compresses to be steeped in normal saline solution. The temperature is to be taken night and morning and duly recorded on the chart.

Period of Passive Movement.—This stage may be said to begin as soon as the three following signs are present, viz.:—(1) Complete absence of a rise of temperature for at least twenty days. After this period of apyrexia the clot is in all probability solidly anchored. Experience teaches us that in seven or eight days the original clots are solid enough to adhere, and the only cause for anxiety is the elongated clot which does not contract adhesions or undergo absorption as soon.

(2) Absolute indolence of the veins on palpation both superficial (saphena) and deep (back of calves, popliteal hollow, internal aspect of the thigh and inguinal fold).

(3) Retrogression of the œdema as shown by marked diminution of the rotundity of the limb and a characteristic flabbiness. In cases of double phlebitis the examination must comprise both limbs.

These favourable symptoms are manifested towards the 25th or 30th day from the onset of the phlebitis, when in the interval there has been no rise of temperature. This is a departure from the classical delays formerly imposed which were too protracted and kept patients immobile for unnecessary periods, much to their detriment. On the contrary we must have recourse to passive movement as soon as possible in order to avert numerous complications.

At this stage we must follow a methodical course in the employment of the exercises. To begin with, we shall seek to restore suppleness to the joints, commencing with the joints of the foot and toes. This gains time and gives patience until the time comes to move the large joints, which would be dangerous before we are certain of having secured adequate rest for the limb. At the same time the skin of the limbs may be lightly, very lightly, rubbed. After two or three days the rubbing may be extended to the whole limb, taking care to avoid undue pressure on the vasculo-nervous bundles. After five or six days of passive movement we may proceed to flex on the knee, if necessary, by breaking down any adhesions.

The next thing to engage our attention will be the stiffness of the muscles, which is often very pronounced. The wasting of the calf and thigh is well marked, and this atrophy explains the awkward gait of the patients. It is better to postpone the stage of getting up until we have in some measure restored strength to the muscles and suppleness to the joints. This is the next stage of the massage which is gradually made to act on the deeper structures and is followed by passive movements of the articulations.

At last the time comes for the patient to leave his bed. It is quite unnecessary to make him use crutches if the directions given in the preceding paragraph have been followed. He need only steady himself by grasping the furniture as he goes along, and ere long all he will require is a stick. In this way, by the end of the second month, the patient should have recovered the complete use of his limbs and be able to walk, without any trace of stiffness.

When once he is up and about it is unnecessary, and even undesirable, for him to wear an elastic stocking. Should the circulatory troubles persist, with œdema and cyanosis increased by standing, this is no reason to advise an elastic stocking, which hinders not only the normal venous circulation, but also the collateral circulation that has been set up. At most a crêpe bandage may be allowed.

Treatment of Subacute Venous Septicæmia.—This is a special variety of phlebitis, often limited to the superficial veins and displaying a tendency to recur or shift from one spot to another. Just when we are tempted to look upon the patient as convalescent from his attack of phlebitis and to allow him to get up, inflammation supervenes along the track of the same saphenous vein or the one on the opposite side. Each fresh attack is accompanied by a rise of temperature lasting two or three days. I can recall the case of a man who is now having his tenth recurrence of phlebitis. In these cases complete recovery may be indefinitely postponed, and becomes a veritable "Will-o'-the-wisp."

The treatment of these cases is not carried out on exactly the same lines. The patient must be immobilised for seven or eight days, which is sufficient to obviate the risk of embolism in superficial phlebitis. Effleurage (light rubbing), which is so much recommended in these cases, has not, on the other hand, given me satisfactory results, though done with the greatest gentleness; indeed, it has seemed to set up fresh attacks of inflammation. These patients should therefore be left at rest, and after the period of immobility the joints should be passively moved, but no friction applied over the veins.

Treatment of the Sequelæ.—The shorter the period of immobility the less marked will be the œdema. After an appropriate course of treatment all that remains should be a little non-painful stiffness, which a little rubbing and massage will cause to disappear.

On the establishment of the collateral circulation it is not uncommon for varicosity of the veins to develop, and it is difficult not to credit this with an inflammatory origin, though as a rule it is considered to be of purely mechanical origin. Its occurrence is ushered in by a feeling of weight in the legs on standing but not in walking, and here elastic stockings may advantageously be recommended.

Pain, too, is a common sequela of phlebitis. This may be due to irritable vessels or distension and congestion of the veins with neuropathic reactions In these cases electrotherapy and hydropathy are indicated.

Sometimes we get neuritic manifestations more especially affecting the sciatic nerve. In this case electrotherapy is preferable to hydrotherapy.

The Surgical Treatment of Phlebitis—Surgical intervention may be called for in several different conditions :—

(1) In the acute stage of ordinary phlebitis and in most cases of relapsing subacute inflammation there can be no question of surgical measures. When, however, the recurrent inflammation becomes fixed in a particular area, ablation of the packet of varicose veins will effect a cure.

(2) In presence of persistent pain accompanying varicose dilatation excision is also indicated, possibly on a large scale.

(3) Lastly, in presence of a varicose ulcer, resection of the ulcer if not too extensive, or of the veins at a distance, is indicated. In cases of persistent pain accompanying tiny venous dilatations with atrophic changes in the skin threatening ulceration, such as is often met with in the internal malleolar region, here agan surgical intervention will often effect a cure.

APEX-TREATMENT
FOR
PULMONARY CONSUMPTION.

By WILLIAM EWART, M.D.Cantab., F.R.C.P.,

Consulting Physician to St. George's Hospital and to the Belgrave Hospital for Children; formerly Assistant Physician and Pathologist to the Hospital for Consumption, Brompton.

I.

THE PULMONARY FACTOR.

In human tuberculosis there are two chief aspects for study, the bacillus, and the lung as its main breeding ground and supply. The fact that tuberculosis is largely a lung question obtained practical recognition more than a third of a century before the discovery of the bacillus, in the foundation of the Brompton Hospital, followed by other special hospitals and later by our sanatoria. Little headway was made with pulmonary treatment because its other factor was unknown. Another third of a century has nearly elapsed since Baumgarten and Koch's discoveries led to the foundation of the tuberculosis laboratory, and of the laboratory treatment of the bacillus. Remarkable strides have been made in the study of that treatment, but comparatively little headway with the cure. Is this perhaps because the lung factor has received during that period hardly any of that attention which has been lavished with such admirable thoroughness upon the infective factor? That question might, with some fitness at this date, have been considered at our Annual Conference for 1913. As that was not possible, owing to the programme having been already completed, it is now presented in these pages.

The "specific" treatment by tuberculin has been aimed also at the other localisations of tubercle, but at none of them on so large a scale. In most of them some alternative treatment is available and is preferred. We do not treat a tubercular joint or a tubercular peritonitis by tuberculin; we hand them over to the surgeon for short work. Incidentally it is significant that in tubercular arthritis the latest appeal from the quick cure by the knife has not been addressed to tuberculin but to heliotherapy, which has justified itself as a cure independently of it. That fact bears upon the special question as to the efficacy of tuberculin, which is not under discussion here, though, strange to say, it has again been raised for discussion elsewhere at the end of these thirty-three years. The special point before us is why the pulmonary affection is almost alone in being, practically speaking, restricted to the "general" tuberculosis cure, whether by tuberculin or open-air sanatorium, or by both combined. The reason for this is not that it is in any sense less "local" than the others. In a tubercular peritoneum or joint we can hardly guess where the original lesion may have had its site. In the lung we know that it has its site at the apex; we can listen for it there, and now we can even see it. Pulmonary tuberculosis is eminently a local affection, and essentially an "apex question": *no apex-tuberculosis, no phthisis.* The difficulty is that for reasons peculiar to the lung the local trouble is not readily accessible to the knife; and moreover that it is still assumed to be inaccessible to any other form of localised treatment, excepting, perhaps, the intra-pulmonary injections which have recently been advocated. But this remains only an assumption until conclusive evidence shall have been obtained from a further study of the pulmonary factor. It is not suggested that that study has been entirely neglected. Freund took it in hand in 1858 in connection with prevention; and modern surgery has taken it in hand with remarkable results for the rescue of the hopelessly advanced stage. But if we turn to the special hospitals and sanatoria for treatment, and to the preventoria for prophylaxis, do we find that any attempt has been made to localise the treatment to the site of the disease? The purpose of this inquiry is contained in the three questions: "*Is there* any local apex-treatment?" *Should there* be a local apex-treatment?" "*Can there* be any local apex-treatment?" These will be further considered in subsequent issues.

THE
LEUCOCYTE COUNT IN GAS AND ETHYL CHLORIDE ANÆSTHESIA.

By WILLIAM GUY, F.R.C.S.,
Dean, Edinburgh Dental Hospital,
ALEXANDER GOODALL, M.D., F.R.C.P.,
Lecturer in Physiology,
AND
H. S. REID, M.D., F.R.C.S.,
Carnegie Demonstrator of Physiology, School of Medicine of the Royal Colleges, Edinburgh.

In a previous paper (*a*) we postulated that an anæsthetic which caused little demonstrable disturbance of function was, *cœteris paribus*, to be preferred to one which had more effect on the body apart from the anæsthesia. We have already demonstrated the effect of several of the short-time anæsthetics on the circulation (*b*). As the result of these observations we were able to show the great advantage of the use of gas and ethyl chloride in sequence over the use of ethyl chloride alone. We have now made a series of observations on the leucocyte count immediately before and immediately after the use of this sequence. So far as we are aware, no account of the effect of the short time anæsthetics on the leucocyte count has ever been published. The subjects of observation were all patients at the Edinburgh Dental Hospital. After the mouth had been examined a sample of blood was taken from the lobule of the ear and diluted in the Thoma-Zeiss leucocytometer pipette, with 1 per cent. acetic acid tinged with methyl green. The anæsthetic was then administered. An inhaler containing one gallon of nitrous oxide was applied and rebreathing was allowed. After five respirations a measured quantity of ethyl chloride (from 1 to 3 cc.) was introduced and this mixture was re-breathed for 25 seconds. The operation was then carried out and immediately thereafter a second pipette (which had previously been carefully compared with the first one) was charged. The number of leucocytes in 400 of the small squares of the counting chamber was then ascertained and the number per cmm. thus determined.

In order to exclude the possibility of fallacy from differences in the concentration of the blood we made frequent observations of the hæmoglobin content at the same time as the leucocyte count but never found any difference between the amount present before and after the anæsthetic.

Some of the patients were suffering from suppurative conditions and showed a leucocytosis. It is well known that persons showing a leucocytosis due to one cause may not react in the usual way to a second stimulus to leucocyte increase, and therefore we have placed in a special category all those cases in which the initial count exceeded 10,000 per cmm.

We also excluded cases where there were signs of obvious illness. Otherwise the cases in Table I. are consecutive.

26.	F	19	10,800	9,000
27.	M	19	11,000	8,000

It is probable that the error in the leucocyte count may reach but does not exceed 20 per cent.

We find that of the 90 cases in Table I., 47 show no difference greater than 20 per cent. between the pre-anæsthetic and the post-anæsthetic count. Of the remaining cases, 30, or 33.3 per cent. show an increase in the leucocyte count; 13 or 14.4 per cent. show a decrease of more than 20 per cent.

A point of passing interest is that the average count (before anæsthesia) in 90 practically healthy persons was 7,277 per cmm.

Of the 27 cases in Table II., with a pre-existing leucocytosis, 13 show no change exceeding 20 per cent., 1 shows an increase exceeding 20 per cent., and 13 show a decrease exceeding 20 per cent.

It may be concluded (1) that the administration of gas and ethyl chloride in sequence as described causes little disturbance of the leucocyte count, such disturbance as does occur being usually in the direction of a slight increase, and (2) this comparatively negative finding is a factor additional to those which we have already demonstrated in favour of the advantage of this procedure in the induction of short time anæsthesia.

THE TREATMENT OF INFANTILE PARALYSIS.

By PAUL B. ROTH, F.R.C.S., &c.,
Surgeon to the Kensington and Fulham General Hospital, Senior Clinical Assistant in the Orthopædic Department, London Hospital.

This paper is concerned with the treatment of the results of anterior poliomyelitis. It may be summed up in two words—Prevent Deformity. This is done by :—

1. Maintaining at all times the natural temperature of the affected part.
2. Relaxing the affected muscles, so as to prevent them from becoming stretched, and their opponents from becoming contracted.
3. Exercising the affected muscles so soon as they show any return of voluntary power.
4. Employing suitable mechanical means.

1.—Maintain at All Times the Natural Temperature of the Affected Part.

It is still an everyday occurrence to meet cases of I.P. which have been treated for years by instruments, massage, and electricity, without any attempt having been made to keep the limb warm. When the instrument and stocking are removed, we find a bluish wasted leg, disfigured with the scars of broken chilblains, and inches shorter than the other one. Yet if the limb be kept warm, there will be little wasting, no discoloration or chilblains, and no shortening. The way to keep it warm is not by massaging it, but by putting on sufficient clothing. The best plan is to add layer after layer of stocking until the limb becomes as warm as the other. When the child is fitted for an instrument or boot, the measurements must be made over this extra clothing. Unfortunately the instrument-maker of the present day usually makes his measurements upon the naked limb, and the efforts of the parents to keep the limb warm by extra stockings only result, when the instrument or boot is applied, in cramping of the toes, pressure sores, and callosities. The parents soon realise this and omit the extra clothing.

In addition to the stockings, after the boot is put on, a gaiter lined with cat or rabbit skin should be worn, with the fur turned towards the limb. Girls wear these gaiters until they grow up: as soon as boys are old enough they can be put into trousers and the trouser leg of the affected side lined with the fur.

At night it may be necessary to wear a stocking, but not nearly so much clothing is required then as is the case in the daytime, for in bed it is the rule for the paralysed limb to get warm without extra clothing of any kind. This is due to the warmth afforded it by the healthy limb, to the little loss of heat undergone when cosily tucked up in bed, and also to the horizontal position of the limb. This leads to an important point in treatment, never to let the affected limb hang down. Whenever the child is resting the affected limb must be supported: if a leg, on a chair; if an arm, then in a sling.

Be the vaso-motor system of the limb ever so seriously affected, it can still carry on its work if sufficient help is given it by minimising the heat loss and reducing the peripheral pressure. And if it carry on its work every one of the tissues will receive its normal amount of blood, and so many of the classical signs of I.P. will never even make their appearance.

To what extent the sequelæ of an attack of I. P. are due to the vaso-motor disturbance I am not prepared to say, but that they are largely due to it there can be no question. Even the muscular paresis is largely influenced by it, for one has frequently noted good movement in a limb when made warm before the fire, in which, when cold, there appeared to be no voluntary movement at all.

Every morning and evening the circulation may be still further assisted by ten minutes in a warm bath (100° F.).

It is customary in these cases to order massage, because it is able to restore the circulation in the part for the time being; but if, as in the simple manner above described, the part be kept warm and the circulation good always, the need for massage vanishes, and it can then only be considered a luxury, not a necessity.

2. RELAX THE AFFECTED MUSCLES, SO AS TO PREVENT THEM FROM BECOMING STRETCHED, AND THEIR OPPONENTS FROM BECOMING CONTRACTED.

Nothing is more disheartening to the orthopædist than the examination of case after case of I.P. of the lower extremity in which the foot has been allowed to become dropped, though actually under medical treatment all the time. With the dropping of the foot the tendo Achillis becomes contracted, and often secondarily to this, the hamstrings follow suit. A cutting operation is now usually necessary to repair the negligence of the medical attendant. If a case be treated efficiently from the start, a tenotomy will never be required.

The harm caused by allowing the foot to become dropped is only in part the obvious disability of a shortened tendo Achillis, which can be put right by a tenotomy; much more to be deplored is the stretching and elongation of the paralysed extensor muscles. For when recovery begins in the nerve, and impulses are sent along it to dorsiflex the foot, though these impulses would cause healthy muscles to do so, they are quite unable to produce a sufficient contraction in the stretched muscles. If the muscles are already relaxed, they are in the best condition for contraction, but if stretched they are in the most unfavourable condition for it. Dr. Abercrombie, of Sheffield, to whose recent paper (1) I shall again refer, gives the following explanation of this: "When a muscle-fibre is overstretched, its sheath (sarcolemma) is brought into a state of tension, causing lateral compression of its contents. By this lateral compression the longitudinal channels which compose the dark bands will be compressed one against the other, and this will have the effect of obstructing the orifices of the minute pores through which the translucent material gains entrance to the channels. This affords a simple mechanical explanation of the ill-effects of overstretching; for since the ingress of the translucent material into the channels of the dark band is impeded, so also will physiological contraction of the muscle be hindered or prevented, even though the nervous mechanism of the muscle be intact."

The treatment to be adopted, therefore, is in some manner to relax the affected muscles, that is, in this particular case, to prevent foot-drop. This is done by applying a right-angled splint to the foot and leg, either a tin "night-shoe" or a Thomas club foot splint (*a*), and making the child wear it day and night, until recovery in the muscles is well advanced. In all probability it will need to be worn at night for years. It is not sufficient to tell off a parent or even a masseur to move the foot every day, to prevent it from becoming dropped; slowly but surely the foot will become fixed in a dropped position if it be not placed in the splint.

It is to be hoped that this principle, namely, the relaxation of paralysed muscles during the period of repair in the nerve supplying them will soon be generally recognised, and employed in all nerve lesions where recovery is hoped for. Mr. Sherren (2) has advocated it in injuries to the peripheral nerves, but so far as I know its general use has never been suggested in I.P., certainly never in I.P. of the erector spinæ or of the quadriceps extensor.

3. EXERCISE THE AFFECTED MUSCLES SO SOON AS THEY SHOW ANY RETURN OF VOLUNTARY POWER.

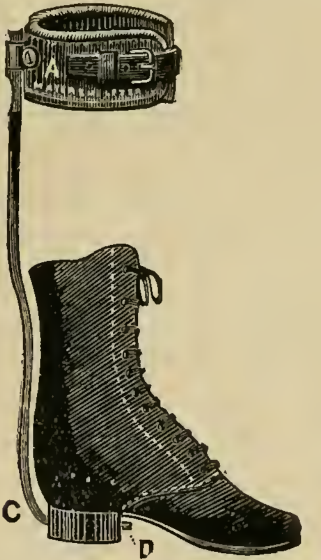
The method of exercising the muscles and of discovering whether they possess voluntary power has been clearly described in Dr. Abercrombie's paper, "The Treatment of Muscular Paresis by Means of Eccentric Movements," from which I have already quoted. In that paper he emphasises the importance of eccentric as opposed to concentric movements. "By a concentric movement is meant the ordinary movement of a muscle which does work while becoming shorter; on the other hand a muscle is said to perform an eccentric movement when it does work while becoming longer." He, however, merely touches upon a point which I specially wish to emphasise, namely, the importance of the stimulus of the patient's will. This was recognised many years ago: thus—"as soon as possible rouse the action of the paralysed muscles by the most important functional stimulus of the will, which cannot be replaced by any other." (3) In carrying out the eccentric exercises the patient's will is specially brought into play, and it is perhaps largely owing to this that they prove so successful.

Apart from set exercises every effort is made to get the patient to move and use the affected limb. If it be the leg that is paralysed, he is encouraged to walk and run and skip; if the arm, then the good arm is bound to the side for a fixed time every day and the affected only allowed to be used.

(*a*) The latter is quite efficient, and much the cheaper of the two.

4. Employ Suitable Mechanical Means.

If the condition be so severe that he cannot walk, or that he can only walk with great difficulty, or with obvious tendency to the production of deformity, a walking instrument must be provided, but not otherwise. For when an instrument is worn, although it favours muscular recovery to a certain extent, *e.g.*, in a very bad case which could not walk at all without it, yet after a certain point has been reached it hinders recovery by doing the work of the muscle for it. It should therefore be applied sparingly and not retained too long. The application of a walking-instrument and T strap in order to correct a simple paralytic varus or valgus has always appeared to me to be peculiarly unnecessary; it can be so much better corrected by thickening the sole and heel of the boot on the outer or inner side, as the case may be. This wedged sole can be applied, moreover, to the patient's ordinary boot at the cost of a couple of shillings; whereas the walking-instrument and T strap cost perhaps 30s., and necessitate a surgical boot. When there is paralysis of the extensor group of muscles only, causing foot-drop, it is not necessary to apply a walking-instrument double to the knee, with uplifting toe-spring attached; a much simpler and lighter appliance is a posterior uplifting toe-spring, supplied by Mayer and Meltzer. This was first described by my father, Bernard Roth. (4) It consists of a flattened posterior steel (see Fig.), which is moulded to the contour of the leg; its upper end is riveted to a metal band passing round the calf; its lower end turns suddenly forward at right angles and fits into a slot in the back of the boot-heel. This is not visible from the front, and only slightly noticeable from the side.



Cliché of Inf. Par. Splint.

I cannot enter further here into an account of the mechanical treatment of I.P. I hope to deal with it adequately in a subsequent paper.

Remarks.—The stock treatment for a case of I.P. is "Massage and Electricity." Almost any doctor will tell you so. This idea has also got firmly implanted in the mind of the public; it should be our endeavour to uproot it. As regards massage, I am unable to see that it does anything more than improve the circulation of the part for the time being, and for just so long as the massage lasts; for half-an-hour perhaps out of the twenty-four; whereas sufficiently warm clothing will keep the circulation at its best for the whole of the twenty-four. As regards electricity in these cases, has anyone ever shown that it is really of value? It was introduced by Duchenne (5) in 1855, who firmly believed that it would cure I.P.; he even thought it could produce a new muscle. Since then it has gradually caught on, and now in every electrical department, twice a week, we find the paralysed limbs of little children stuffed into baths along with a couple of electrodes.(*a*) A prayer by a Christian Scientist would possibly be more useful. Even when the case is treated with care, and each paralysed muscle stimulated separately with a button electrode, is it not doubtful whether good is done?

Though I cannot hope this single paper will shake the universal faith in "massage and electricity," I do trust it will do something to spread the knowledge of a better treatment which may roughly be summed up in two sentences—*keep the limb warm, and apply a night-shoe.*

CLINICAL RECORDS.

NOTES ON CASES ILLUSTRATING THE RELATION OF CERTAIN AFFECTIONS OF THE SKIN TO CARDIO-VASCULAR DISEASE.

By DAVID WALSH, M.D.Edin.,
Senior Physician, Western Skin Hospital, London.

The following cases illustrate the association that in the author's opinion commonly exists between many affections of the skin and cardio-vascular disease. It is fairly obvious that any serious defect in the heart or arteries must correspondingly disturb the balance of the peripheral circulation. That being so, it necessarily follows that the normal processes of nutrition, secretion, repair, defence, and so on, must be modified by the abnormal cutaneous blood supply. The author's view is that one of the early signs of many forms of valvular disease is the diminution or loss of the speedy recovery from non-destructive traumatism which characterises the healthy skin. The sun which simply tans a sound skin is apt to set up a severe dermatitis in the case of a patient suffering from heart disease or from arteriosclerosis. The author has notes of a number of cases of sun dermatitis and summer eruption, in all of which some serious organic or functional cardio-vascular defect has been found. Some of the skin eruptions symptomatic of cardio-vascular defects are of an acute nature, but the greater number are naturally of a chronic or recurrent nature, extending in some instances over many years. Any dermatologist who wishes to put the matter to the test will find an unlimited number of cases among his patients. The skin is subject to incessant attacks of micro-organisms of many kinds, which are kept at bay, as it were, by the circulation of a copious supply of blood adequate in quality and in quantity. When the cutaneous circulation is damaged through disease of the heart or blood vessels, the natural defences of the blood (opsonins, phagocytosis, etc.) are correspondingly decreased, and the organisms from without are able to secure a footing in the deeper tissues, where they give rise to

---

(*a*) The apparent good produced by this treatment is due to the hot water.

secondary vascular changes, such as plugging of vessels, perivascular inflammation, arterio-capillary fibrosis, and so on.

R. G., m., 41, housekeeper, came to hospital complaining of a rash affecting limbs and trunk; the scalp, face and neck also affected. Had been under a private doctor for six months; said at one time he "peeled from head to foot." When first seen he had a fine papular rash, running into sheets in places, moist and diffuse in groins. The general health had always been good, except that he suffered at times from rheumatic pains in joints. He now had pain in right shoulder. His mother suffered from rheumatism, and died at 78. The digestion was good, a little shortness of breath, no palpitation. Pulse 100, arteries somewhat thick for age. Cardiac dulness one inch to left of nipple line, impulse to lower border of fifth rib. A systolic mitral murmur was heard, conducted into axilla. The seborrhœic dermatitis almost disappeared under treatment, but recurred more than once, and he was under treatment again 16 months after his first visit. The patient had at no time shown symptoms calling attention to the heart. The view taken of the case was that the cardiac defect had rendered the skin vulnerable to invasion by the seborrhœic organisms, and at the same time less amenable to local treatment. To the disturbance of the blood supply was also attributed the chronic and recurrent nature of the malady.

N. T., female, æt. 32, s. teacher, came with several small patches of alopecia areata of 12 months' duration; she had a previous attack at 7 years of age. Her father died of a fit in early life. Mother living, in good health. General health good, slight muscular rheumatism at times. She had a slight operation a year ago—the removal of a small growth from breast. She suffers from a little indigestion and shortness of breath at times, but has no palpitation. The pulse is 80, compressible; arteries good. The cardiac dulness is one inch outside nipple line, and on lying down after exertion a mitral systolic murmur is heard, conducted into axilla. The murmur could not be heard when patient was standing up. (In all these cases a stethonoscope was used for auscultation.)

This case illustrates the association of alopecia areata with valvular disease. In the author's experience it is the rule rather than the exception. The only condition that led to the examination of the heart and the detection of a latent murmur was the alopecia areata. The causation of the bald patch is probably the same as in the skin eruption—the weakened surface circulation acts as a predisposing condition, and permits the exciting traumatism—in the shape probably of seborrhœic organisms—to gain a footing and more or less effectually block the local blood supply. The shedding of the hair is an accident due to the sudden plugging of the small capillaries of the hair bulbs.

S. W., f., 51, married, complaining of rosacea of face of four years' duration; suffered from rheumatic pains in joints at time, but otherwise has had good health. She has of late years complained of indigestion, shortness of breath and palpitation. A mitral systolic murmur was heard, conducted into axilla; cardiac dulness 1 inch outside nipple line. A rough systolic murmur also heard over tricuspid area. The rash was papulo-erythematous.

T. P., f., 28, s. teacher, complaining of loss of hair for several years past. The hair was thin, especially along vertex and at crown; formerly very thick. The scalp was thin and light; much dandruff. The pulse was 120, compressible. She had suffered from dyspepsia, but did not complain of shortness of breath or palpitation; ankles sometimes swollen at night. The face flushes readily. The cardiac dulness was found 1 inch outside left nipple line. There was a mitral systolic murmur audible at angle of scapula.

The foregoing is one of many cases of premature baldness associated with valvular disease of the heart. As a rule the condition does not respond favourably to treatment.

C. F. W., m., 16 years, school, for two years had suffered from a severe papular and pustular eruption of face. The papules were not obviously connected with the follicles; were dull red; and pus, when present, was scanty. The heart was found to be dilated—dulness 1½ inch to left of nipple line. The patient went in for football, running, and other violent exercises, and had fainted a few weeks previously. He had been in the habit of using strong carbolic soap for the face. The case was diagnosed as acneitis, due to the irritant action of the soap in a cardiac subject. With rest and heart tonics the heart condition rapidly improved, but the skin eruption persisted months after the heart murmur had disappeared and the heart had returned to a normal size. A von Pirquet test was applied, with positive results. Treatment was then commenced with .0003 injection of tuberculin (T.R. mixed), increased gradually. The face condition gradually improved, and is now practically well.

Various other chronic tuberculides and paratuberculides have been noted in patients suffering from cardio-vascular disease. Several cases of lupus and of ulerythema have also been met with, but their number has not yet been large enough to permit of any sound deductions. The association of skin rashes with cardio-vascular affections opens up an exceedingly wide and important field of investigation. It seems not unlikely that disturbance of capillary circulation may afford a key to many affections of internal organs—that is to say, like the skin, they are unable to establish a healthy reaction against traumatism.

OPERATING THEATRES.

HAMPSTEAD HOSPITAL.

Abdominal Cases Operated on by Mr. Jackson Clarke.

Case 1.—Acute Obstruction (Adhesions).—Boy, æt. 10. History of pain in his side, chiefly at night, for some weeks. Four days ago acute abdominal pain and vomiting. Large dose of castor oil gave little result. Since then pain has been nearly constant and vomiting frequent. Absolute constipation. Abdomen tender all over, more marked over epigastrium. No movement. Tympanitic note over whole of abdomen. Lies with knees drawn up. Peritonitic facies. Temperature, 99.8°; pulse, 74. *Operation.*—$CHCl_3$—ether. Abdomen opened. Intestine found gangrenous, strangulated by adhesions formed after operation for appendicitis 3½ years ago, and a second operation for ventral hernia three months later. Three feet of intestine excised. One dainage tube. Tube out on 23rd day. Post-operative bronchitis. *Result.*—Cured.

Case 2.—Extra-uterine Gestation.—Woman, æt. 31. Patient has never lost a period. Two months' history of a constant vaginal flow, almost disappearing with rest, and increased by exertion. Pain for the same length of time in the right side of the abdomen. Seven days ago sudden severe pain in "stomach," accompanied by profuse perspiration and the loss of about half a pint of blood. Two days ago something came away with a few sharp dragging pains. Temperature, 100.2°; pulse, 88. *On examination:* Abdomen flaccid and moves well. In no pain or respiratory distress. Uterus palpable of the size of a 3½ months' pregnancy. To the right of the uterus pain and tenderness and a second mass not quite so large as the uterus. Complains of pain on micturition. *Vaginal examination.*—Uterus enlarged; cervix hard and os closed. Marked tenderness in right fornix, and a distinct tumour is palpable bimanually. *Operation.*—C.E.—ether. Abdomen opened and a large cystic tumour found on the right side, bound down by numerous adhesions. Adhesions broken down, and tumour brought out through the wound, which ruptured in the act, revealing a two months fœtus. Oophorectomy performed on the right side. Wound healed by first intention.

CASE 3.—Carcinoma of Ascending Colon and Cæcum.—Man, æt. 63. Abdominal pain and vomiting once a week for six weeks. Extreme constipation. No hæmatemesis or melæna. Losing weight. No gastric previous history. Abdomen soft, not distended, and gives tympanitic note all over. No visible peristalsis. Large semi-mobile tumour to right of umbilicus about the size of a cocoanut. Tender on deep palpation. Liver enlarged; descends half-way to umbilicus. Bronchitis. Some enlarged glands felt per rectum. No enlarged inguinal glands. Inguinal scrotal hernia. *Operation.*—Median incision. A large carcinomatous tumour presented about the size of an apple, and involving the ascending colon and part of cæcum. Too adherent for excision. Meso-sigmoid very short. Ileo-sigmoidostomy performed. Lateral drainage tube. Tube out on fifth day. Uneventful recovery.

CASE 4.—Suppurative Cholecystitis; Appendicitis.—Man, æt. 56. Eight days' history of continuous pain in right iliac fossa. Bowels not open four days. No vomiting. On admission marked resistance and tenderness and some fulness over seat of pain; maximum tenderness over McBurney's point. Bowels open day of admission. Urine normal. Temperature 99.2°; pulse, 100. *Operation.*—On admission. Battle's incision. Appendix inflamed, but not gangrenous. Cæcum injected. Appendicectomy. One tube. Tube out on seventh day. Wound healing well. Fourteen days after operation much pain, suggestive of renal colic. Two days later markedly jaundiced. *Second operation.*—Fortnight later. $CHCl_3$—ether. Incision over gall-bladder, which was found to be inflamed, shrunken and perforated. Some purulent matter escaped. Cholecystectomy. One tube. Subsequently suffered from diarrhœa and incontinence of fæces, which improved a good deal before discharge. Tube out on 15th day. On discharge both wounds healed. Some swelling of legs.

CASE 5.—Perforated Duodenal Ulcer.—Woman, æt. 31. Twelve hours' history of acute pain and sudden onset, between shoulders and whole of right side of abdomen. Vomited four times after pain began. Bowels open twice. No jaundice. Past history of dyspepsia. Looked ill on admission. Abdomen rigid. Temperature, 98°; pulse, 80. *Operation.*—On admission. $CHCl_3$—C.E.—ether. Median subumbilical incision. Pelvis contained quantity of turbid, inoffensive blood-stained fluid. Nothing abnormal found in pelvis. Supra-umbilical incision. Turbid fluid again found. Nothing abnormal in lesser sac. Old healed scar of gastric ulcer. Fluid escaping from second part of duodenum; ? post-peritoneal perforation. Posterior gastro-jejunostomy performed; no clamps. Two tubes, one for upper wound through a third incision made in posterior abdominal wall below last rib, and second tube down to pouch of Douglas. Uneventful recovery. One of the tubes (pelvic) out on fourth day. Date of removal of upper tube not noted.

CASE 6.—Enlarged Prostate.—Man, æt. 63. Eleven years' history of increasing frequency of micturition. Only able to pass a small quantity at a time, and cannot hold it. Frequency at night, five or six. No pain on micturition. Pain in back frequently. *Operation.*—C.E.—ether. Supra-pubic prostatectomy. Five separate adenomata of firm consistence were enucleated from the prostate, which was otherwise normal. Tube out on eighth day. Passed urine per urethram on 12th day. Complete control on discharge.

Remarks by Mr. Jackson Clarke will appear later.

TRANSACTIONS OF SOCIETIES.

THE NEW LONDON DERMATOLOGICAL SOCIETY.

MEETING HELD THURSDAY, JULY 10TH, 1913.

DR. DAVID WALSH, the President, in the Chair.

DR. ALFRED EDDOWES brought (1) a patient who he considered exhibited a tendency to rodent ulcer. The patient, æt. 39, had a good family history. At the age of 15 she suffered much from constipation, which she neglected for years. She had a high colour always. About ten years ago she noticed the formation of a large number of white spots on her face (milia). Eight years ago she underwent an operation in Dublin for a small sore on the left cheek "which used to run a little, and when it first appeared used to bleed frequently after washing." Soon after the operation a white spot formed on the sides of the scar and very slowly increased until she consulted Dr. Eddowes last September. It was then clearly a rodent ulcer, nearly an inch in diameter. As Dr. Eddowes had not any available beds at the time the case was passed on to a surgeon at a general hospital, and he removed the growth freely with the knife. The disease, however, again recurred at the lower edge of the scar. It was freely destroyed with a Paquelin cautery by Dr. Eddowes ten days ago. During the operation a small rodent ulcer which had been previously detected on the side of the nose was also burned out. It is in the very red (chronically hyperæmic) skins that hypertrophy of epithelium naturally occurs. Milium is one manifestation, warts another, as also most probably is rodent ulcer. Suspecting this, Dr. Eddowes has treated the skin of this patient's face, and with satisfactory result: the milia are disappearing and the redness of the skin is less marked. Some red, chronically hyperæmic skins do not appear to owe their high colour to excess of, or chemical changes in the secretion, as in the case of acute seborrhœa, but rather to glandular inadequacy of skin—to coin a word for the moment—a *sub*-sebaceous state. Incidentally, he said he had operated upon many rodent ulcers—primary and recurring—and had never had a recurrence after his operations. He only undertook those of reasonable size. Extensive cases he always passed on to surgeons, who occasionally had been too conservative. He personally never operated on such cases without full permission from the patient to take away or destroy as much skin and other tissue as he thought fit. Those present would see that he acted up to his conviction in the present instance.

(2) A case of acute seborrhœa, with band alopecia and pustular acne. The patient, J.B., æt. 26, says she has had a tendency to lose hair and to have pimples or boils on her forehead for six months. She now has acute seborrhœa of scalp, face, ears, chest and back. Upon the forehead there is a band of almost total alopecia, an inch wide; over this area, and on forehead, back and chest are points of suppurating acne. From many of the follicles are protruding comedones and sebaceous plugs. The condition on the forehead seems to occupy a position between alopecia areata and folliculitis decalvans. All the affected areas are redder than normal.

DR. H. SAMUEL showed (1) a man, æt. 45, with lupus verrucosus of the right buttock, of six years' duration. The disease had spread to the inner side of the left gluteal fold, but under X-ray treatment the margins of the original patch were clearing and flattening in a satisfactory manner. The patient also showed some rosacea.

The PRESIDENT recalled a similar case shown by him before the old Dermatological Society of Great Britain and Ireland in 1906 (vide *Brit. Journ. Derm.*, vol. xviii., p. 117), in which a dose of old tuberculin was given, producing a most severe reaction.

DR. EDDOWES referred to a similar case under his own care, in which lupus existed in other parts. He injected mercury with some benefit.

(2) A woman, æt. 34, with lupus erythematosus of the nose and scalp. The patch on the nose had been scraped, having been originally diagnosed as lupus vulgaris.

(3) A young woman with lupus vulgaris of the face, who had received many different kinds of treatment, including Finsen light, ionisation, and salicylic and creosote plaster. Some recent patches had been treated with carbonic acid snow in acetone.

Dr. J. D. P. McLatchie showed a young man with syphilis. The patient had contracted a chancre 2½ years ago, followed by the usual secondary symptoms, and he had received only two months' treatment. Eighteen months ago a lump appeared in the position of the original chancre, and during the last six months he developed some red, scaly lesions on the forearms.

The President thought that tertiary lesions on the penis were not uncommon, and they might be mistaken for a re-infection. He drew attention to the frequency of symmetrical lesions, perhaps parasyphilitic, about the backs of the forearms in tertiary syphilis.

Dr. Tom Robinson considered that cases of "relapsing chancre" (Hutchinson) were fairly common, and that they resulted from insufficient treatment.

Dr. Samuel said that the spirochætes might get locked up in the primary lesion with the formation of a fibrous nodule. This should be got rid of as quickly as possible.

Dr. Robinson showed a case of

PSORIASIS IN A CHILD OF 5½.

The disease first showed itself two years ago, and the eruption had persisted up to the present time. There was no family history of psoriasis.

Dr. P. S. Abraham remarked that cases of psoriasis were distinctly rare under the age of three years. He had seen about twenty under this age.

Dr. John Peterson (introduced) referred to the localisation of the disease in infancy, and said that he had never seen lesions of psoriasis upon the backs of the elbows or the fronts of the knees in very young patients. He believed that the scalp was primarily affected in nearly all the cases, and that if this condition were vigorously treated with an ointment of 15 gr. of salicylic acid to the ounce of pure lard the condition would improve. When the eruption had spread to the body and limbs he was accustomed to treat it with resorcin ointment and pure liquid tar. A salicylic acid and sulphur soap should be used in the bath at least three times a week after all the spots had disappeared.

Dr. D. Vinrace showed a little girl, æt. 11, previously exhibited before the Society, with persistent sores upon the face after varicella. She had been tested by the Von Pirquet test with a negative result. Altogether 28 spots, leaving scars, had occurred on the face and body. Most of the lesions had been treated with the acid nitrate of mercury, but lately the solid carbon dioxide had been used.

The general opinion of the meeting was that the condition was one of multiple lupus.

The President showed a young man from Dr. Robinson's clinic at the Western Skin Hospital with alopecia areata of two years' duration associated with valvular disease of the heart. He also read notes of an investigation recently pursued by himself into 36 consecutive cases of alopecia areata, in only four of which no serious sign of cardio-vascular disease could be found, while 24 were found to have valvular disease.

Dr. Vinrace showed (2) a man, æt. 23, with pityriasis versicolor limited to the left shoulder, of several week's duration.

Dr. McLatchie suggested that the explanation of the unusual localisation of the disease was that the patient wore the same vest continuously, day and night, and slept upon his left side.

Dr. Samuel referred to the low degree of contagiosity in cases of this affection.

Dr. Eddowes considered that the usual text-book treatment of two or three days was seldom, if ever, sufficient.

BRITISH OTO-LARYNGOLOGICAL SOCIETY.

Meeting held July 16th, 1913,

Dr. Frederick Spicer presiding.

Dr. Percy Jakins exhibited the following cases:—(1) A man, æt. 24, with a plum-coloured growth on the left vocal cord; (2) a girl, æt. 22, with a small sessile growth upon the left vocal cord; (3) a woman, æt. 35, with perforation of the nasal septum and extensive specific ulceration of the tonsils and fauces, healing rapidly under treatment by "606."

The Chairman said with regard to case 1 (vascular laryngeal growth) that before making a definite diagnosis of its nature he would like to remove a portion and examine it microscopically.

Dr. McCulloch mentioned a case of papilloma of the larynx, which was ultimately considered to be malignant, but which disappeared under treatment by ultra X-rays (see *British Medical Journal*, October 17th, 1908. There has been no recurrence of the growth.

Mr. Charles Heath and Dr. Walker Wood concurred in the opinion that the diagnosis should be cleared up in the way the Chairman suggested, but that if the growth were obviously innocent, it should be removed by the indirect method. Discussing case 3 (specific ulceration), Mr. Charles Heath said from its appearance he had no doubt that the faucial ulceration was rapidly healing under treatment. The nasal septum, however, was showing less evidence of repair, and this was doubtless due to the non-vascular structure of the cartilage.

Dr. McCulloch (introduced by the Chairman) exhibited four case of extreme deafness (labyrinthine) showing improvement by treatment with the ultra X-rays, tuning fork and other tests being given.

The Chairman expressed himself as deeply interested at the results so far obtained in such hopeless cases; he would be glad to know more about this treatment.

Dr. Walker Wood said that in reference to the cases shown by Dr. McCulloch, he had personally examined and tested them before treatment and again three months later after treatment. There was an undoubted improvement, and although it was but slight, it was encouraging. He hoped on a subsequent occasion that Dr. McCulloch would contribute a paper to the Society explaining his views of the nature and action of these ultra X-rays.

Mr. Charles Heath was also much interested in the cases which had been exhibited by Dr. McCulloch, and said that if the improvement in the hearing was not great, it was unmistakable. This was a class of deafness which had not hitherto been relieved by any form of treatment, and if the X-rays utilised in this manner were likely to be effective, the sooner the fact was known the better. He gathered that Dr. McCulloch had been giving attention to this form of treatment since 1908, and had read some of his publications on the subject in 1909 and 1910. Possibly, at another meeting of the Society Dr. McCulloch might be willing to read a paper upon this treatment, when it could be more fully discussed, and when there might be more cases available upon which to form an opinion of its merits.

Mr. Charles Heath showed:—(1) A case of aural suppuration of 40 years' duration in one ear and 38 in the other, with an interval of two years between the operations. There had been complete recovery with excellent hearing on each side after conservative mastoid operations by the method devised by the exhibitor of the case. (2) A case of chronic aural suppuration of two years' duration with cholesteatoma in both ears (specimen shown) with perfect restoration of structure and function in each ear after conservative mastoid operation by the exhibitor's method.

The Chairman congratulated Mr. Heath upon case 1, and said the ears of this patient were the most satisfactory results of mastoid operations he had ever seen. With regard to case 2, the result of operation showed how much advance there has recently been in the treatment of chronic aural suppuration; not long ago, a patient such as this would have undergone the radical operation, and would have been made deaf by it.

Dr. Pullin drew attention to the cosmetic effects of these two cases of double mastoid operations, and congratulated Mr. Heath upon the results.

Mr. Heath, in reply, said with regard to the case of 40 years' duration, she was referred to him by Dr. Meggison, who did not anticipate that hearing could be restored, but in the hope that arrest of aural suppuration by mastoid operation might put an end to the severe headaches which had marred the whole life of the patient, whereas the result was that hearing had been restored to 20-50ths and 14-50ths, which was really excellent hearing; the headaches, too, had abated. With regard to the double cholesteatoma case, prior to the introduction of the conservative mastoid operation in 1906, Mr. Heath, too, would, under such conditions—as the Chairman had stated—have performed radical operations, and this patient would now be more or less deaf, whereas at present her hearing was more acute than the average girl of her age.

A set of new instruments used in conjunction with the naso-pharyngoscope for the direct treatment of the Eustachian tubes, was shown by Dr. Walker Wood,

Mr. Charles Heath also exhibited several new instruments.

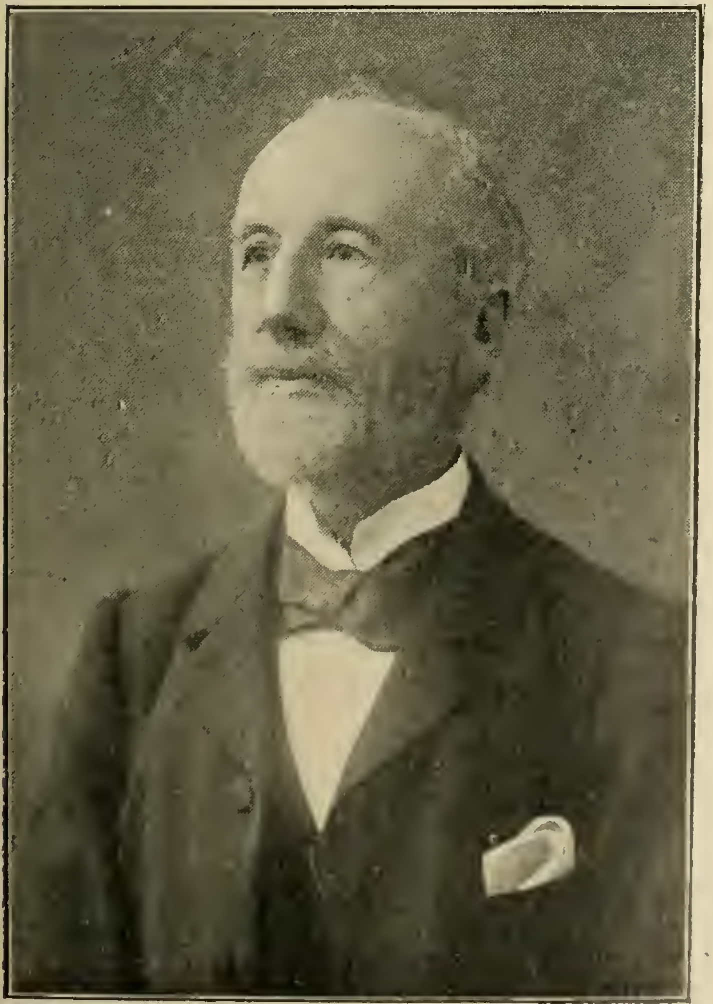
A paper by Dr. James Harper (Glasgow) on "A New After-Treatment of Intra-Nasal Operations" was then read.

SPECIAL REPORTS.

THE EIGHTY-FIRST ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION, HELD AT BRIGHTON, 1913.

[By Our Special Representative.]

It is just twenty-seven years since the British Medical Association met at the "Queen of Watering Places," and once again, true to its traditions, the municipality of this famous South-coast resort has extended a magnificent welcome to the many hundreds of members now attending the annual meeting. The town is crowded with visitors, and no pains have been spared by the local members of the profession or by the civic authorities, both of Brighton and the sister corporation of Hove, to render the 1913 meeting a pleasurable one.



Dr. William Ainslie Hollis.

The New President.

Dr. William Ainslie Hollis, Consulting Physician to the Royal Sussex County Hospital, the newly-elected President of the Association, is a man who richly deserves the honour bestowed upon him, for he has always striven to promote the best interests of the medical profession. Born in 1839 at Lewisham, he was educated at Brighton College and Trinity College, Cambridge, where he took his M.A. in 1866. He entered St. Bartholomew's Hospital, qualifying as M.B.Cantab. in 1867, and becoming M.D. in 1871. He held the appointments of Medical Registrar and Casualty Physician at St. Bartholomew's Hospital, subsequently becoming attached to the medical staff of the Chelsea, Brompton and Belgrave Dispensary.

In 1876 Dr. Hollis, having been elected F.R.C.P.Lond., left the Metropolis for Brighton, in which town he has identified himself prominently with the work of the British Medical Association. He was Chairman of the Brighton branch and was afterwards elected to the Branch Council and representative of the South-Eastern Branch. He was also Treasurer of the local defence fund, and at the present time is Consulting Physician to the Royal Sussex County Hospital, in which institution he has always taken the keenest interest.

Dr. Hollis has held the office of President of the Brighton and Sussex Medico-Chirurgical Society and the Natural History Society.

The Association may well congratulate itself in having chosen such a distinguished physician as its leader in this critical time in its history.

General Arrangements.

The conservatism of the medical profession is once more illustrated by the fact that at the annual representative meeting at the Town Hall, Hove, on Monday last, the motion to form a trade union was defeated by more than two to one, after the case for and against had been fully debated.

The President delivered his address last night in the Dome before a crowded and distinguished audience, taking for his subject "The Medical History of Brighton." The Mayor of Brighton, Alderman Thomas Stanford, opened the proceedings by welcoming the Association to Brighton. A replica of the presidential badge of office was presented by the local Division to Dr. Hollis as a token of the esteem in which he is held by his colleagues in the town.

The address in medicine is to be delivered to-day in the Music Rooms of the Pavilion by Professor George R. Murray, Physician to the Royal Infirmary, Manchester, and that in Surgery is to be delivered to-morrow by Sir Berkeley Moynihan, Surgeon to the Leeds General Infirmary.

The annual temperance breakfast has become quite an established function of the annual meeting. It is held under the auspices of the National Temperance League, and will take place on Thursday morning, July 24th, at 8.15 a.m., at the Royal Pavilion. The President, Dr. Hollis, will preside, and Mrs. Mary Scharlieb, M.D., M.S.Lond., will deliver the address. The proceedings will terminate at 9.30.

Religious Services.

A service will be held this afternoon at 3 p.m., at St. Peter's Church, which will be conducted by Canon Hoskyns, the Vicar. It is expected that the Bishop of Truro will preach the sermon. The members attending the service will robe in the Pavilion and will then march to the church, headed by the Corporations of Brighton and Hove.

This morning, at 9 am., a Roman Catholic service will be held at the Church of St. John the Baptist, Bristol Road, conducted by Canon Mgr. Johnston. D.D.

The Work of the Sections.

The scientific work of the Association will be conducted in sixteen sections, all of which will meet in the conveniently situated quarters of the Municipal Technical College and the Municipal Training School, kindly placed at the disposal of the Association by the Brighton Education Committee. These fine buildings are adjacent to each other, and they afford ample accommodation not only for the whole of the sections, but also for the Pathological Museum. Many interesting discussions are to take place, among which may be mentioned that in the Section of Medicine on "Fibrositis and Muscular Rheumatism." to be opened by Dr. A. P. Luff; that in the Section of Surgery on the "Diagnosis and Treatment of Primary Carcinoma of the Stomach," to be opened by Mr. G. H. Makins, C.B.; and that in the Section of Gynæcology and Obstetrics on "Affections of the Urinary Tract Complicating Pregnancy," to be opened by Sir J. Halliday Croom. The Section of Medical Sociology will attract considerable attention this year, for one of the subjects down for discussion therein is "Hospitals in Relation to the State, the Public, and the Medical Profession," to be opened by Professor Benjamin Moore, Mr. J. G. Gibbon, D.Sc., Prof. W. Pfeiffer, Dr. Adolf Gottstein (Charlottenburg), and Prof. Grober (Jena).

The Social Functions.

To-night there is to be a concert and ball to be held in the Pavilion and Dome by invitation of the Mayor of Brighton. The annual dinner takes place on Thursday evening in the Hove Town Hall. On Friday evening the local Division is giving a soirée in the Hove Town Hall. On Thursday afternoon the Mayor of Hove, Alderman Barnett Marks, has invited a large number of members to a garden party in the picturesque grounds of St. Ann's Well Gardens. Numerous excursions and visits to places of interest in the neighbourhood have been arranged for. Dr. Hugh Stott, the Mayor of Lewes, has invited a party to visit the historic county town of Sussex, and the visitors will afterwards be entertained at tea by Mr. and Mrs. Frankfort Moore. The Duke of Norfolk has graciously thrown open his magnificent seat, Arundel Castle, to a large party. Other places included in the programme are Chichester, Tunbridge Wells, Eastbourne, Shoreham, Worthing and Portsmouth. A Masonic reception will take place this afternoon immediately after the Church service, by kind invitation of the W.M. and Wardens of the Hova Ecclesia Lodge.

The arrangements made for golfers are excellent in every way. The Hon. Secretary of the Golfing Subcommittee is Dr. P. Stanhope Eves, 14 North Street, Brighton, and the principal event is the competition for the Ulster Cup, which was presented to the Association by the Ulster Medical Society in 1909. This will be played for on Thursday, July 24th, at the East Brighton Golf Club, 18 holes, bogey play, under handicap (limited to 18). Lady visitors, members of recognised golf clubs, may be made temporary members of the Ladies' Golf Club at the Dyke. Tennis and cricket are also provided for.

It will be seen that nothing has been left undone to ensure the comfort and happiness of members of the Association and their wives attending the annual meeting at Brighton.

The Exhibition.

Members should not fail to make a tour of the annual exhibition, held in the Corn Exchange adjoining the Dome. Here they will find displayed in tempting fashion the latest thing in foods, beverages, drugs, instruments and books. It has been decided this year to keep the exhibition open on Wednesday night, the occasion of the Mayor's soirée. In spite of the fact that the International Medical Congress will be held so soon after the Brighton meeting in London, it cannot be said that the customary attractiveness of this annual display has diminished aught thereby, and therefore members will miss a good deal if they do not seize the opportunity, at least once during their visit, to walk round the stalls and inspect the various exhibits.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, July 19th, 1913.

At the Gynæcological Congress, Hr. Kehrer, Dresden, introduced the subject of

The Lime Constituents of the Blood in Physiological and Pathological Pregnancies and in the Puerperium.

In normal pregnancy, he said, the lime constituent in the blood was raised. In nephritis gravidarum there was a slight diminution of lime, and in eclampsia a more considerable diminution. In the normal childbed, on about the ninth or tenth day, there was a considerable diminution, due to loss of blood, secretion of milk, and perhaps to the diminished food supply, which was deficient in lime in the early part of the puerperium; it might stand in some relation to the tetanoid condition that was present in 80 per cent. of all lying-in women. During the lying-in period of women who had suffered from nephritis or eclampsia during pregnancy there was a striking increase in the lime constituent.

Hr. Lampe, Munich, discussed the relation between

Basedow's Disease and the Genitals.

In all the cases observed, 25 in number, of Basedow's disease a protective ferment was found as against the Basedow thyroid, and in most cases against the thymus and ovary—*i.e.*, the Abderhalden reaction was positive with Basedow serum plus thyroid in all the cases, and in most with Basedow serum plus thymus, and Basedow serum plus ovary. Samples of Basedow serum plus other substances—kidney, liver, muscle tissue, etc.—all failed to show the reaction. From these evidences it appeared that Basedow's disease was a dysthyroidism, that in most cases of the disease the thymus failed to act properly, and that the germ glands in most cases underwent a deviation from the normal. The diminished function of the germ glands was therefore to be looked upon as secondary to the imperfect functional activity of the thyroid. The matter was further discussed by Hr. v. Graff and J. Novak, Vienna. After examination of 36 women suffering from Basedow's disease the following conclusions had been reached:—Basedow's disease was frequently associated with signs of infantilism and disturbances of menstruation which, generally as oligo- or amenorrhœa, preceded the disease. In many cases the disease stood in a timely and probably causal relationship with the three most important phases of sexual life—viz., puberty, gravidity and the climacteric. In many cases the cause of the Basedow's disease must be sought in the hypo-function of the genital apparatus. Two illustrative examples were noted—viz., outbreak of the disease after operation and sterilisation of the healthy woman by application of the Röntgen rays. The speakers then passed on to thyroid and gestation. Enlargement of the thyroid commenced during gestation only in from 44 to 49 per cent. of the cases. In an exhaustive examination of women before the commencement of pregnancy (500 women were examined), 40 per cent. of them suffered from struma. An increase took place during the actual labour, but a diminution during the puerperium. Glycosuria, both spontaneous and alimentary, was more frequent in women with enlarged thyroids than in those without enlargement. In eclamptic cases the enlargement of pregnancy was frequently absent. The evidence before them tended to disprove the assumption that the climacteric furthered the disposition to the development of goitre.

Hr. Schickele, Strassburg, spoke on

The Substances that Excited Uterine Contractions and Internal Secretions.

The exciting substance in pituitrin had nothing to do with the heightened blood pressure. It was present in extracts of hypophysis (both anterior and posterior lobes), which had no pressure-raising action. There-was no specific action, therefore, in the posterior lobes. Substances that excited uterine contractions were to be met with outside the hypophysis, as, for instance, in the ovary, corpus luteum, uterus, thyroid, mammary gland, as well as in the fœtus and placenta. The blood serum of the umbilical cord, as well as that of the pregnant woman herself, also contained it. It was also true of the kidneys, liver and spleen. These substances were present both during pregnancy and at other times. It could not be determined with certainty that the action was stronger during pregnancy than at other times.

Hr. Kalledey, Budapest, read a paper on the

ÆTIOLOGY AND ORGANOTHERAPY OF HÆMORRHAGE FROM THE UTERUS.

He had treated 21 cases of dysmenorrhœa with ovarian extract. In all the cases complete recovery was brought about. Of these 21 cases five were pregnant. From these observations the speaker concluded that dysmenorrhœa was due to a hypo-function of the ovary. The speaker also treated meno- and metrorrhagia with extract of the hypophysis, also with a good result. With extract of corpus luteum he had succeeded in arresting hæmorrhages in five cases.

AUSTRIA.

Vienna, July 19th, 1913.

RADIUM RAYS IN THE TREATMENT OF UTERINE CARCINOMA.

The discussion of Dr. Wertheim's communication on the radium treatment of uterine carcinoma was carried on at the recent meeting of the K.k. Gesellschaft der Aerzte in Vienna.

Dr. A. Jungmann stated that he had been treating lupus cases with radium radiations since 1905. Up to the present his series of patients in this department totalled 650. Among those were 350 cases of chronic cutaneous tuberculosis; and his experience tended to prove that radium is a powerful therapeutic agent in this special domain of clinical pathology. It proved specially effective in the treatment of lupus of the mucous membranes. Among his radium patients there were also 160 cases of carcinoma. Most of these cases were of cutaneous cancer of a more or less aggravated type; but there were also some of deep-seated cancer: some inoperable; some who had refused to be operated on; and others who had come in subsequent to operation. Jungmann here laid stress on the general fact of his experience that radium presented a possibility to patients, who, according to all pre-existent laws of surgical prognosis and practice, would have been given up for lost, and left with nothing to look forward to but an early and agonising termination of life, of—at least in a considerable proportion of cases—a substantial prolongation of life under conditions by no means so burdensome. Recurrence did, indeed, take place in many instances, nevertheless the fact remained that, even in such cases, a repetition of the treatment—continuously maintained—had the effect of maintaining the patient in good condition. He advocated the administration of large doses in the treatment of carcinoma, inasmuch as the fact had long been recognised that small doses had but an irritant effect.

RADIUM TREATMENT OF PROSTATIC TUMOURS.

Dr. R. Paschkis had treated an inoperable sarcoma of the prostate with radium radiations, and the patient, after an interval of two and a half years, still maintains the appearances of complete recovery. No result had been obtained in the treatment of a number of malignant tumours of the bladder. The explanations advanced for the failure of radium therapy in those cases—over and above the fact that they were always very far advanced, sometimes inoperable, and sometimes even recurrent—was that the quantity of radium, and the time-period of its application, were too limited in each case. He had never seen erasion or direct cauterisation applied to the mucous membrane of the bladder; but he had appled the radiations, *experimenti causa*, for a long time to a quite small papilloma of the otherwise normal bladder of a female patient. The result was that the papilloma remained unaffected, and the mucous membrane normal. He had also applied the radiations *per urethram* in two cases of prostatic hypertrophy. Both these were old men who had been affected for years; and in each case the local change had produced chronic and complete retention of urine, without any change of the general condition.

CLINICAL VALUE OF RADIO-ACTIVITY: RADIUM *v.* MESOTHORIUM.

Dr. E. Ranzi stated that for the past four years radium rays had been employed in von Eiselberg's clinic: in the treatment of inoperable tumours; and in the after treatment of those cases in which operation had been resorted to, and complete extirpation found impossible. A beneficial effect was distinctly noticeable in a good many of the tumours; in one case, indeed, the primary tumour disappeared completely. On the other hand, some cases proved completely refractory to the radiations; in one instance, the application of the rays actually seemed to increase the rate of growth of the tumour every time they were employed. In a relatively small number of cases, there had been some hæmorrhage after the application of the rays. This would suggest the desirability of caution in the employment of the radium rays in the vicinity of large blood-vessels.

Dr. L. Freund stated that when carcinomatous tissues were exposed to radium radiations in small quantity, the superficial layers of the new growth were unquestionably destroyed. But this destructive agency did not reach the deeper structures: partly on account of the fact that the intensity of the radiations varied approximately, as the inverse square of the distance, and partly on account of the absorption of the rays by the tissues penetrated. The deeper layers of the tumour, and the scouts of the new growth, the infected lymphatic glands, which from the beginning occupied a position widely separated from the primordial mass, were reached by a dose of radiations which were so far from being destructive that they were merely irritating; accordingly, we find that the glands grow vigorously while the superficial layers of the original cancerous growth are shrinking. On this account, dosage with small quantities of radium rays is suited to the treatment of quite superficially situated, and shallow, carcinomatous growths. So our efforts must be directed to the raising of the distant effect of the radiations to the highest available standard. It is only this distal action that can give any special value to the treatment of large tumours with radium or mesothorium; in its absence there is no appreciable difference obtainable which can tend to rank such above the other incompletely radical methods of removal of malignant growths. Such essential increase of "action at a distance" can be obtained only by means of powerful sources of radiation—such as can over-compensate for the weakening of the rays by tissue absorption and effect of distance. Such sources require the presence of large quantities of the radio-active material. We cannot yet determine whether radium or mesothorium will prove to be the survivor in this competition for ultimate clinical precedency.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

PROFESSORSHIP OF BACTERIOLOGY, UNIVERSITY OF EDINBURGH.

As was very generally anticipated and desired, the Curators have appointed Dr. James Ritchie, Superintendent of the Royal College of Physicians Laboratory, to be the first incumbent of the new Chair of Bacteriology. Dr. James Ritchie is too well known in Edinburgh for it to be necessary to utter any encomium on his appointment. He is a graduate of Edinburgh, and served as resident under Professor Greenfield. Thereafter he went to Oxford, where he was successively Lecturer, Reader, and Professor of Pathology. When Dr. Noel Paton resigned the Superintendentship of the College of Physicians' Laboratory in order to take up his duties as Professor of Physiology in Glasgow, it was universally felt that the College was fortunate in being able to secure Dr. Ritchie's services, and under his control the Laboratory has flourished exceedingly. Dr. Ritchie's contributions to bacteriology are numerous; among them we may mention the textbook of which, along with Professor Muir (Glasgow), he is author. In the meantime, Professor Ritchie will not sever his connection with the College Laboratory, as it is understood that, pending the creation of a University Bacteriological Department, arrangements are in contemplation for his continuing his work there. The University has made a fortunate selection in electing Professor Ritchie.

Clinical Teaching in Edinburgh.

At the same meeting of the University Committee at which Dr. Ritchie's appointment was announced, there was also made public the fact that the University had entered into an agreement establishing a close and intimate relationship with the Royal Infirmary as to the work of the Pathological Department and as to the teaching of clinical medicine, surgery and gynæcology. Without entering into details of the agreement, which are, of course, of purely domestic interest and depend on the local circumstances, the general tenour of the document is to create a Board of Selection for teaching appointments, consisting of representatives of the Infirmary Board, the University, and the Royal Colleges. This Selection Board reports two names to the General Board of Managers. Another matter settled by the agreement is the status of the Professor of Pathology, who hitherto has had no connection with the Pathological Department of the Infirmary. Now, the Professor of Pathology is to be consulting pathologist to the institution; the present pathologist continues in office, and is appointed lecturer on morbid anatomy by the University. The four senior ordinary physicians become senior lecturers on clinical medicine, and examiners; the assistant physician, lecturer on clinical medicine, with a fixed honorarium; while the University is to pay and appoint clinical tutors. The senior lecturers, with the University clinical professors, are to form a Board to control clinical teaching. The privileges of the extra-mural students are safeguarded in the agreement, but the whole effect of it will be to bring clinical teaching and pathology more and more under the control of the University, as now appears inevitable in view of the changes which are at present taking place in medical educational methods, and the increasing costliness of equipment.

Power of Scottish Insurance Commissioners to Prosecute.

An important decision has been given by a full bench of judges in the Justiciary Appeal Court. The bench consisted of the Lord Justice-General, the Lord Justice-Clerk, and Lords Johnstone, Dundas and Guthrie. The question was raised on an appeal against convictions under the National Insurance Act obtained at the instance of the Commissioners for non-payment of contributions on behalf of servants. The competency of the complaints was objected to on the ground that the Commissioners had no title to prosecute, and this appeal was sustained by the Court, which quashed the convictions and allowed the appellants full expenses. The leading judgment was given by the Lord Justice-Clerk, who enumerated the four qualifications recognised in Scotland as conferring the right to prosecute, the last of them being a statutory right. The Insurance Act, although it gave the Commission power to sue, was silent as to any power to institute criminal proceedings, nor could it be clearly inferred from the wording of the Act that it was the intention of the legislature to confer such power. Lord Dundas, concurring, said that it must be inferred that the Legislature, while providing that the Commissioners might sue, had deliberately refrained from giving them the right to prosecute. No person other than the Public Prosecutor was entitled to prosecute unless the Statute so provided. Lord Guthrie, who also agreed, said it would be no public loss if the result of this decision was to lead those responsible for framing Statutes to see that, if power to prosecute was desired, it was expressly given. Lord Johnstone concurred. Lord Dunedin said he had only a vote in the case of divisions among their Lordships, and their Lordships were unanimous. He indicated that he might have been prepared to take the leap and hold that power to prosecute was implied. He was most emphatically of opinion that with the assistance of the Scottish Law Officers the matter ought to have been made perfectly clear in the Statute.

Assistant to the Edinburgh Medical Officer of Health in Connection with Sanatorium Treatment.

For this appointment, to which a salary of £500 per annum attaches, there were only three applicants, of whom Dr. John Gray, County Tuberculosis Officer, Gloucester, was elected. He is a Glasgow graduate, and has filled the position of Assistant Police Surgeon at Bradford, Assistant Superintendent of Leeds Infirmary, and Superintendent of the Sanatorium at Bridge of Weir.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

ALCOHOLIC QUACK MEDICINES.

To the Editor of The Medical Press and Circular.

Sir,—Inasmuch as in my evidence before the Select Committee I gave a prominent place to alcoholic quack medicines, I have been interested in the correspondence under the above heading that has been going on in your pages. I agree with writers who point out what a vast amount of injury is being inflicted by these compounds. This was forcibly suggested indirectly in Prof. Saundby's clinical lecture which gave rise to the discussion. Many quack medicines are in themselves merely inert trash; they do harm only in such cases as pass into chronic or mortal phases owing to delay in applying scientific treatment. This indirect injury is bad enough, whether it leads in simple cases only to such minor results as complete loss of hair in curable alopecia, or in serious diseases to grave endings, lingering torment and death from lupus or cancer. The peculiarity of the alcoholic nostrum is that it inflicts actual injury upon at least 95 per cent. of the people who employ it. Alcohol is not a remedy for any disease, and where it is able to mitigate for a short time the symptom of mental depression it does it at the cost of reaction, pernicious and damaging in a high degree. My evidence before the Committee was restricted to the question of newspapers and quack advertisements. My task was to show that the newspapers were either aware of the nature of the traffic they were abetting, or more or less culpably negligent in not taking notice of the facts constantly being thrust upon their attention. The majority of leading papers either have medical men on their staffs or have regular medical contributors, and if the proprietors had any real desire to keep their pages clean they could soon put an end to the present scandal. Papers of inferior class justify themselves on the ground that quack advertisements find ready admission to their contemporaries of the highest class, and to those that set themselves up especially as the enemies of humbug and fraud. All the newspapers assume the *rôle* of patriots, defenders of the national honour, guardians of the welfare of the poor. It is, I repeat, a gross scandal that the majority of these papers should be deriving great incomes from a traffic the nefarious character of which they must be fully alive to.

I am, Sir, yours truly,
Henry Sewill.

The Old Rosery,
Earlswood Common.
July 17th, 1913.

OBITUARY.

THE HON. WILLIAM HENRY LANGLEY, C.M.G., F.R.C.S.I.

Particulars have now come to hand respecting the fatal illness and untimely death of this distinguished Irishman, the Principal Medical Officer of Southern Nigeria since 1911, formerly Deputy Principal Medical Officer in Northern Nigeria, and Principal Medical Officer in the Gold Coast Colony. Dr. Langley was only 44 years of age at the time of his death. He had enjoyed good health up to the middle of last April, but about that date he first showed signs of impaired vigour. He had recently passed through a strenuous time during a tour of service in discharge of his official duties, and the mental strain evidently had told upon him. Under medical treatment his condition improved for a while, but on June 1st feverish symptoms set in. These were accompanied by bloodlessness, and he sank from heart failure on the evening of June 11th.

The funeral took place at four o'clock on the afternoon of the following day with full military honours. The Deputy-Governor of Southern Nigeria, in the absence in England of His Excellency Sir Frederick Lugard, the Governor, Members of the Executive and Legislative Councils, and other officials attended From Government House, Ibahan, the funeral cortége slowly passed to the Colonial Church, at which it was met by the Right Rev. Bishop Tugwell and the Colonial Chaplain. The coffin, covered with beautiful wreaths, rested before the chancel during the first part of the burial service. At the cemetery the remainder of the service was read very impressively by the Bishop, and when the firing party had performed its sad duty the "Last Post" was sounded, and the many who were present silently bade farewell to their much-lamented friend and colleague.

Dr. Langley received his medical education at the Carmichael College of Medicine, Dublin, and at the Royal College of Surgeons in Ireland. In due course he became a Licentiate of the Irish Colleges of Physicans and Surgeons, taking the Fellowship of the College of Surgeons in 1902. His official career was very distinguished. He served in the Borgu operations of 1897-98. for which he received a medal and two clasps; in the Kontagora Expedition of 1900, for his services in which he was mentioned in despatches and received a medal and clasp; and with the Kano Sokoto Expedition of 1903, his services in which were rewarded with special mention, a clasp, and the honour of Companion of the Most Distinguished Order of St. Michael and St. George. In an official communication to the Right Hon. Lewis Harcourt, M.P., Secretary of State for the Colonies, His Excellency Sir Frederick H. Lugard, Governor of Southern Nigeria, wrote under date June 12th: "Dr. Langley's death is a very great loss indeed to Nigeria. I had intended to recommend him to you for the proposed appointment of Director of Medical Department under the scheme of amalgamation. There is no officer in the West African Medical Service who has the personal knowledge of both Protectorates possessed by Dr. Langley. I have known him intimately since I recommended him for appointment, and I feel his death keenly as a personal loss."

And in an official communication from the Colonial Office, dated June 4th, 1913, to Dr. Langley's brother, who lives in Dublin, the following extract from a letter sent the previous day to his sister is given in the form of a despatch: "Mr. Harcourt desires to associate himself with the terms in which Sir F. Lugard refers to the late Dr. Langley, whose unfailing tact, good temper, and keen practical intelligence, united to his great experience of West Africa renders him exceptionally well fitted for the important post for which it had been Sir F. Lugard's intention to propose him."

Lastly, the *Southern Nigerian Government Gazette Extraordinary*, Lagos, Thursday, June 12th, 1913 (Vol. VIII., No. 37), contains the following paragraphs:—

"It is with the deepest regret that his Honour the Deputy Governor has to announce the death of the Honourable W. H. Langley, C.M.G., Principal Medical Officer, Member of the Executive and Legislative Councils, which took place suddenly at 9.30 p.m. on the 11th instant."

"Mr. James feels that he will be carrying out the wishes of His Excellency the Governor in expressing in this form the deep general sense of the great loss that not only the Government, but also the whole European and native community of Southern Nigeria have suffered in the untimely death of this distinguished officer.

"Dr. Langley, apart from the great services he has rendered to West Africa as Deputy Principal Medical Officer in Northern Nigeria, as Principal Medical Officer in the Colony of the Gold Coast, and recently as Principal Medical Officer of Southern Nigeria, can well be said to have endeared himself by charm of manner and quality of mind to all with whom he came in contact, whether officials or non-officials, throughout West Africa."

REVIEWS OF BOOKS.

TROPICAL MEDICINE. (a)

There is no difficulty in understanding the appreciation which the medical public displayed in their reception of the first issue of this genuinely epoch-making text-book of one of the most modern and most important of all the sciences—and the appurtenances thereof. The volume is thoroughly encyclopædic in the comprehensiveness of its range of vision and appropriation of material, and the fact that it was practically the first in time, as well as spaciousness and quality, to deal with one of the most important of the Imperial concerns of our cosmopolitan British Empire has contributed to make it one of the most brilliantly valuable —whether considered from the mental or material view-point—of the whole "University Series" which collectively represents so well the contemporary high-water mark of British Medicine and Surgery. The dedication to Sir Patrick Manson, "the Founder of Scientific Tropical Medicine," serves as a frontal index of the high ideals of duty and discrimination at which the authors and publishers have so successfully aimed.

In this second issue the authors have displayed in the necessary revision, addition, and increased illustration the same untiring energy and discriminating zeal which were so well portrayed in the first edition. The result now before us—a demy 8vo of xxxii. and 1,747 pages, illustrated with 15 coloured plates and 630 "figures in the text," is one which it would be but ridiculous pretension on the part of a reviewer to criticise seriously within the limits of his allotted space. The conscientious—even devoted—care which has been bestowed upon the accumulation and arrangement of facts garnered from near and far, is displayed throughout every paragraph of this truly colossal work. In fact, the meticulous precision which characterises the presentation of every item conveys something of a prickly sensation to the touch of the reviewer of long-time experience—whose jaded organs of mental sensation have had so little practical reason to anticipate such collision. We feel pretty sure that it was the excess of conscientious devotion to absolute accuracy which dictated the spelling of *Agchylostomiasis,* which, while suggestive of pedantic perfection in the department of etymological research, is decidedly misleading in the present state of English orthography as she is (so very *non*-)phonetically taught. But—such is the impression made by the contents of this truly splendid contribution to the history and practice, the science and art, of medicine—that we feel as if we owed an apology to the authors for firing off this small squib in way of schoolboyish assertion of our privileges. We regard this *Manual of Tropical Medicine* as nearer to perfection in aim and attainment than any that we have had the privilege—the word is chosen with deliberation—of examining in the course of the performance of our critical function for many a long year. No earnest physician at home can afford to be without a copy of this work in his study—and the volume will surely continue to be the indispensable *vade mecum* of every British colonial practitioner, even outside the tropical limits.

(a) "Manual of Tropical Medicine." By Aldo Castellani, M.D. (Florence), Privat-Docent (Naples), Director of the Clinique for Tropical Diseases, Ceylon, Professor of Tropical Medicine and Lecturer on Dermatology, Ceylon Medical College, Member of the Royal Society's Commission on Sleeping Sickness in Uganda, 1902-1903; and Albert J. Chalmers, M.D. (Vic. & Liv.), F.R.C.S.(Eng.), D.P.H.(Cam.), Director, Wellcome Tropical Research Laboratories, Khartoum, etc., etc. Second Edition. (University Series). London: Bailliere, Tindall and Cox. 1913. Price 21s. net.

MEDICAL ELECTRICITY. (*a*)

SEVERAL years have passed since the appearance of the last edition of this book. We prophesy that this, the sixth edition, will have a rapid sale, because it is the standard work which should be consulted by all medical practitioners who employ electricity in the treatment of disease. The number of such medical men is steadily increasing year by year as the scientific writings on the subject have slowly dispelled the cloud of prejudice which used to envelope the employment of electricity in conditions other than muscle-testing. The subject-matter of Dr. Lewis Jones' volume is clear and concise, yet makes easy and agreeable reading.

This edition is thoroughly revised, parts being completely re-written, without greatly increasing the size of the book. There are sections on high frequency, diathermy, galvanic, faradic, and sinusoidal currents, static electricity, and on the use of condenser discharges for electrical testing. There are also chapters on first principles, medical batteries and apparatus, with instructions as to the use of the popular panto or multostat. The Röntgen rays are discussed just as far as is needful for the beginner, as that subject has developed of late years so much that it could not be fully dealt with in a volume containing so much information on other forms of electricity. Perhaps the most interesting chapters are those on Physiological Considerations and General Therapeutic Considerations, which are succeeded by chapters dealing with the treatment by electricity of general diseases, diseases of the nervous system, diseases of the circulatory system, of the respiratory organs, of the digestive tract, of the urinary and reproductive organs, of the joints and fibrous tissues, of the organs of the special senses, and of cutaneous affections. So full a list of diseases yielding to electricity must indeed surprise those who never employ that method of treatment.

Throughout the book, cases are narrated with references to the literature, a method which greatly adds to the interest and the usefulness of this work. Dr. Lewis Jones has had a large experience, and he has not hesitated to assist his colleagues by giving freely of the knowledge he has gained by years of practical work.

CLINICAL PATHOLOGY. (*b*)

THIS book presents an account of the laboratory investigations, whether chemical, histological, or bacteriological, which have a practical bearing upon the diagnosis and treatment of disease. Not more than two different methods of reaching the same object are described. The book is well arranged, on the whole pleasantly written, and is in most respects a trustworthy guide. Its worst fault is an exuberance of certainty which may appeal to the student, but will be accounted for want of breadth of view by many readers. The opening chapters deal with the blood, and in this section very numerous criticisms might be made. The origin of the large hyaline leucocyte suggested by the author is surely unique, and the cell he calls a "transitional myeloblast" on Plate I. forms a quaint picture. The red cells are said to show "apparent amœboid movements" in pernicious anæmia. We are told that blood plates are increased in myelocythæmia. Lymphatic leucæmia is said to be the least common of the "primary anæmias." Six millions per c.mm. is given as the average number of red corpuscles in health.

On page 27 we read: "If that (examination of a blood film) is to be taken as the criterion of our diagnosis, then I have seen an infant pass calmly through an attack of acute lymphoid leucæmia with nothing more deadly than a whoop, and another child shake off in rapid succession the onslaughts of myeloid leucæmia and pernicious anæmia." A most irresponsible statement!

Rogers' work or cholera has apparently been overlooked when we are told that the specific gravity of the blood is of little moment. Hayem's diluting fluid finds no mention, and is better than the formulæ given. The section on bacteriology is more satisfactory. "Anthrax infections in man are extremely rare." What of Bradford? Sections follow on puncture fluids, the urine, the products of different systems of the body, and on histology. Kjeldahl's method is not described on the ground that it is too difficult for ordinary clinical use. This is extraordinary, as second-year students may be required to do a Kjeldahl estimation as part of a professional examination. Hüppert's test for bile is better than those mentioned. We regret to note a great deal of very careless writing. "The relative predominance of *one* of these cells" (p. 191). "Do not blow the plug (flame) out" (p. 152). "Add one drop of ferric chloride" (p. 297). "There is a considerable epidemic of these urines" (p. 226). "If muscle fibres are absent, vegetable fibres may be recognised . . ." (p. 253). We are told the guinea worm is about the thickness of a piece of string (p. 354). We may add that its head is the size of a lump of chalk. There are over a dozen fine examples of the split infinitive. Guaiac is spelt without the initial *a*, and on page 339, we read "loose" for "lose." The story of the curate's egg, old though it be, should either have been told in full or omitted altogether. Space fails us to deal with errors of omission; they are not serious. It seems a pity that such a good book should have so many blemishes which could easily have been put right by a candid friend with a blue pencil.

EXISTENCE. (*a*)

THIS volume had accidentally escaped our notice for an interval too long for the anxious expectations of an ambitious author, and we feel in duty bound to express our regret for the lapse. The text furnished by the title is, indeed, a comprehensively inspiring one. We could, indeed, suggest few, if any, theses which could be made to furnish more ample material or wider range for systematic and syllogistic discussion. The man who undertakes such a task, with sanguine anticipation of success, must be one who had courageously adopted everything knowable as his intellectual province, and had even succeeded in the conquest of that measureless domain with the aid of a persevering skill that has hitherto been given to few, if any, of the most philosophically ambitious.

We should at once say, before proceeding beyond the title page, that the author of this volume is both young and enthusiastic, in years—scientific years, at least—as well as in devoted pursuit of philosophic research and evangelisation. And our perusal did not fail to call up sadly chastened recollections of our own early enthusiasm for scientific attainment—of the days, in fact, in which we fondly hoped that if but a couple more decades could be secured for our terrestrial pilgrimage, and circumstances permitted uninterrupted intellectual progress at the rate of geometrically increasing velocity at which we believed ourselves to be then advancing—why, we would actually know everything—science, philosophy, and the innumerable *et ceteras*. How sadly has the slow but all too sure, disillusion of added years and experience tinted the roseate hue of that prospective vista now that so considerable a section of the same has

---

(*a*) "Medical Electricity." By H. Lewis Jones, Consulting Medical Officer to the Electrical Department in St. Bartholomew's Hospital. Sixth Edition. Pp. 551. London: H. K. Lewis. 1913. Price 12s. 6d. net.

(*b*) "Clinical Pathology." By P. N. Panton, M.A., M.B., B.C.Cantab., Clinical Pathologist to the London Hospital. Pp. 446. London: J. and A. Churchill. 1913.

(*a*) "The Significance of Existence." By I. Harris, M.D. (Koenigsberg), L.R.C.P. and S. Pp. 326. London: Longmans, Green and Co. 1912. Price 6s.

been traversed. And we incline to fear a corresponding experience for the author of the present volume.

Dr. Harris begins at the root of things, and in this regard his conception of scientific exposition would appear to aim at a standard of scientific thoroughness suggestive of that of Lucretius. His text is arranged in sixteen chapters, of which the first is devoted to consideration of "Infinite and Finite." The exponential philosopher who undertakes to discuss the combined and respective connotations of these terms should surely be dowered with clarity ot thought and precision of language. We can hardly compliment our author on the display of either one or the other. The opening sentence is: "All living protoplasm is susceptible to stimulation by its environment and reacts on it in a certain definite manner." And that next following is thus worded: "A sensation becomes the more complex with ascending animal development respectively with the evolutionary stage of a particular organ." The skilled reader will surely agree that science and inspiration are not transmissible by the media of slipshod grammar and conspicuously unkempt diction. And the language and thought of these sentences are maintained throughout every paragraph and chapter of Dr. Harris's work—in discussion of "General Laws of Nature," Purpose, Happiness, Reason, Instinct, Religion, etc., etc.—down to, and through that of "Recapitulations and Conclusions." The last-named—the concluding chapter, opens with the statement: "All existence is an indivisible entity." And we soon reach the sonorous enunciation of a confident belief: "Existence contains from all time and for all time exactly the same potentialities," which is followed by the announcement of: "The fact that to finite beings all forms of existence realise themselves in a series of ascending evolutionary stages depends on their finite proclivities." Such are the guiding sparklets which lead to the will-o'-the-wisp phosphorescence of the concluding sentence of this illuminating paragraph: "From the point of view of the absolute existence there can be no essential difference between existence in patentiâ and in reality."

Why do people think it right to inflict such volumes on a much-suffering humanity?

BARNARD AND STOCKER'S MEDICAL PARTNERSHIPS. (*a*)

THIS volume has been out of print for some time. A new edition has accordingly been called for, and an opportunity has thereby been afforded to the authors of bringing their book more into line with recent decisions affecting the relations between medical men and the agreements giving effect thereto. This book supplies all the needed information regarding the mode of estimating the value of medical practices, the form of articles of partnership, forms of assignment of medical practices, agreements between principals and assistants, and points relating to assistantship with a view to partnership. The law on all these subjects is fully referred to, and numerous legal decisions quoted. The Partnership Act of 1890 is specially dealt with, and notes are given on such of its clauses as are especially likely to affect medical men in partnership. As a useful work of reference this volume will be found extremely helpful to those intending to purchase or to sell a practice, as well as to medical men employing assistants or entering into partnership. We have no doubt that this new edition will be even more popular than its predecessor.

HOW TO CUT THE DRUG BILL. (*b*)

THE author respectfully recommends this book to the Insurance Commissioners "as the text-book for which they are seeking." It appears to us that the author, whose appointments, as stated on the title-page, number a round dozen, including that of Medical Officer to the Southall Jam and Preserving Company, seems to have quite overestimated the importance of his book when he states that it "will prove of inestimable value . . . . to the consultant." In fact, it is hardly worth the reviewer's while to criticise this volume, as the author has already sung its praises sufficiently in his own preface. In a new chapter on invalid foods he refers to those included in his survery as being "guaranteed as of sterling quality." By a curious coincidence every one of the "foods" mentioned appear on the advertisement pages of his book with the single exception of Trommer Elixir. The proprietors of these preparations are lucky in securing such prominence for their wares. The reader is certainly struck by the fact that out of the nineteen advertisements contained in this book the subject matter of only one of these is not dealt with in the text, and this for the simple reason that the one exception is Mr. Hart's own publisher's announcement. The book is accompanied by a green filing card, on which we notice that the word "prescription" is twice wrongly spelt. We should hardly imagine that consultants will find much to interest them in a book of this kind.

AIDS TO GYNÆCOLOGY. (*a*)

THIS evidently popular volume of the "Aids" series has been entirely rewritten and brought up to date—and this process of rejuvenation was necessary, because in hardly any branch of medicine has more progress been effected than in gynæcology. The schematic, more or less "literary" classifications of twenty years ago have given place to more purely surgical and strictly clinical descriptions under pathological rather than anatomical headings. The transformation has been satisfactorily carried out by the author, though we miss some of the illustrations of the earlier editions; in spite of their more or less diagrammatic character they certainly helped to elucidate the text.

Gynæcology is essentially a practical science, and must be learned rather than taught. The most voluminous treatises fail to convey the indispensable "tactus," and as few students can hope to acquire this during the curriculum, the initial knowledge required for examination purposes can be better obtained from a small, didactic work such as this.

VICIOUS CIRCLES IN DISEASE. (*b*)

THE superb binding and lavish use of clarendon and antique type in this book seem to indicate that the author has been riding a hobby while adding to our mental equipment. He has been assiduous in collecting materials to conform to his figure, and if in his zeal he has circled one or two squares who shall blame him? "Chlorosis-metrorrhagia-chlorosis" is one we may quote. Now, metrorrhagia causes secondary anæmia, and probably never alone causes chlorosis, while in true chlorosis metrorrhagia is uncommon. There is a useful chapter on artificial circles, where such factors as social conditions or injudicious treatment form part of the chain. The author gives the following circle—viz., morphinomania—dyspepsia—anorexia—morphinomania. We can present him with one more remarkable—viz., morphinomania—dyspepsia—arorexia and vomiting—abdominal section—morphinomania. This circle in is entirety has been traversed by the same patient four times. If the author does not add greatly to our knowledge he has acquired merit in arranging existing knowledge in a form which must often be of practical value.

(*a*) "Medical Partnerships, Transfers and Assistantships." New Edition, revised and amplified. By Wm. Barnard, M.A. LL.B., Barrister-at-Law, and G. Botram Stocker, Managing Director of the Scholastic, Clerical and Medical Association Ltd. London: The Scholastic, Clerical and Medical Association, Ltd. 1913. Price 10s. 6d. net.

(*b*) "How to Cut the Drug Bill." By A. Herbert Hart, M.S. London: John Bale, Sons and Danielsson, Ltd. 1913. Price 2s. 6d. net.

(*a*) "Aids to Gynæcology." By Jervois Aarons, M.D.Edin., M.R.C.P.Lond., Gynæcologist to St. Anthony's Hospital, etc. Fifth Edition. London: Bailliere, Tindall and Cox. 1913. Price 2s. 6d.

(*b*) "Vicious Circles in Disease." By Jamieson B. Hurry, M.A., M.D. Second edition. Pp. 280. London: J. and A. Churchill. 1913. 7s. 6d. net.

LITERARY NOTES.

An important work on "Arterial Disease and Angina Pectoris," by Sir Clifford Allbutt, M.D., F.R.S., is announced for publication in the autumn by Messrs. Macmillan and Co.

* * *

We understand that arrangements have been made for the translation into English of Prof. Doyen's great work on the "Operations of Surgery." The original work is in five volumes, a second edition now passing through the press; but the translated edition will not exceed three volumes.

* * *

Warwick and Tunstall's "First Aid to the Injured and Sick" (Bristol: John Wright and Son's, Ltd.), has reached an eighth edition. The text has been thoroughly revised and some new illustrations added. It is one of the cheapest and best first-aid annuals with which we are acquainted. In paper it only costs 1s., while in leather cover the price is 2s. 6d.

* * *

"An Elementary Clinical Pathology for Nurses" is the title of a small book published by Messrs. J. and A. Churchill at 1s. It is written by Dr. George Herschell and Mr. Richard Weiss. It has reached a second edition. It deals with the examination of the urine, stools, vomit, sputum and blood, and concludes with the clinical diagnosis of diphtheria. Candidly, we consider this book is more suited for medical men and students than for nurses.

* * *

Miss Margaret French, Sister at the General Lying-in Hospital, Lambeth, has compiled a book which, we think, will be found very acceptable. It is entitled "Babies: A Book for Maternity Nurses." Messrs. Macmillan and Co., Ltd., are the publishers, and the price is 1s. net. It tells all a nurse need know about a young baby, such as bathing, dressing and feeding We note that the authoress recommends three-hourly feeds from the fourth week onwards. The treatment recommended for baby ailments is usually sound, but we think that the statement made regarding talipes, viz., "Severe cases are operated on at about two years," is very misleading. Apart from this and one or two other minor faults, which are quite pardonable, we regard this little guide to infant management as extremely accurate and common-sense in its teaching. We very cordially recommend it to nurses.

* * *

It it good to be reminded, when patients clamour to be sent to some Continental spa, that equal facilities may be had for obtaining various "cures" in our own country. A timely little handbook, containing notes on the therapeutics of radium in the waters of Bath, has recently been published by the Bath Corporation, with the approval of the Bath Medical Committee of the British Medical Association. It has been compiled by Mr. John Hatton, the director of the baths, in order to place before the medical profession the results of the recent investigations of the hot springs of Bath conducted by Professor Sir William Ramsay, K.C.B., F.R.S. Medical men intending to send their patients to Bath would do well to familiarise themselves with the many interesting papers contained in this handbook.

* * *

The present being the fourth issue of "The Social Guide," edited by Mrs. Hugh Adams and Edith A. Browne (London: A. and C. Black. 1913. Price 2s. 6d. net), presumably everyone knows that it is not, as its name might suggest, either a hand-book of etiquette or a reference list of persons "in society." It is, in fact, a hand-book of the social events of the year, or rather to such of them as are supposed to be of interest to London society, and a great deal of useful information it gives. If you want information about cricket matches at Lord's, polo at Hurlingham, racing at Punchestown, travelling in India, the season in Malaya, or West Indians in London, or any other unexpected subject, you will find it here. The book opens with a social calendar, but lacks an index.

MEDICAL NEWS & PASS LISTS.

Society for Relief of Widows and Orphans of Medical Men.

At the quarterly Court of the directors of this Society, Sir Thomas Boor Crosby, President, in the chair, the deaths of Mr. A. Willett, Vice-president, and Mr. L. Archer, Director, were reported. Two gentlemen were elected members of the Society. £1,333 was voted for the payment of the half-yearly grants to the widows and orphans on the books of the Society. Since the last Court three widows had died; one, whose husband had paid in subscriptions £26 5s., had been on the funds since 1885 and had received from the Society £1,540. The Acting Treasurer reported that the total amount received from the estate of the late Mr. James Brickwell was £37,250, bringing in a yearly income of £1,325 10s. A scheme for using this income was submitted to the Court, and was adjourned to the October Court for further discussion. A legacy of £250 had also been received from the executors of the late Mr. Windsor, of Manchester.

Membership is open to any registered medical practitioner who at the time of his election is resident within a twenty-mile radius of Charing Cross. The annual subscription is two guineas; special terms for life membership, varying with the age of the applicant. Full particulars may be obtained from the Secretary at the Offices of the Society, 11 Chandos Street, Cavendish Square, W.

Relief is only granted to the widows or orphans of deceased members of the Society, and the Secretary is constantly receiving letters from widows of medical men who have been left practically penniless, asking for relief, but this has to be refused, as their husbands had not been members of the Society.

Death of Four English Medical Missionaries in China.

A great loss to the medical profession as well as to the missionary cause in China has been caused by the deaths of four doctors from typhus fever. They are Dr. H. S. Jenkins, F.R.C.S.Eng., and Dr. Cecil F. Robertson, F.R.C.S.Eng., both of Sianfu, Shensi; Dr. Egerton H. Hart, of Wuhu, and Dr. F. Hall, of Peking.

Dr. Jenkins, of the English Baptist Mission, after studying at Bristol, qualified as M.R.C.S.Eng. in 1898, and in 1903 obtained both the M.D.Lond. degree and the F.R.C.S. qualification. He had held resident surgical posts at St. Mark's Hospital, London, and the Bristol Children's Hospital, and had been registrar and pathologist to the Mount Vernon Consumption Hospital, Hampstead.

Dr. Robertson, who was the youngest of the four doctors, received his medical training at the Middlesex Hospital. He qualified M.B., B.S.Lond. in 1907, and two years later took the Fellowship of the Royal College of Surgeons.

Dr. Hart, who was widely known in China, spent the last 18 years of his life in charge of the Wuhu General Hospital. It is believed that the attack of typhus fever which caused Dr. Hall's death was contracted from patients in the hospital or out-patient clinic of the Union Medical College in Peking, where for the past four months he had been Dean of the Faculty. He was only 35 years of age.

Gift of a Medical School to South Wales University.

At a meeting of the Council of the University of South Wales last week it was announced that Mr. W. J. Thomas, the Welsh coalowner, would bear all the cost of the new medical school and its equipment. The school will be among the best of the kind in the kingdom.

The Central London Ophthalmic Hospital.

The Duchess of Albany opened the new buildings of the Central London Ophthalmic Hospital last week. The Duchess was received by Lady Stradbroke and members of the committee and hospital staff. Mr. T. B. Archer, Chairman of the Committee of Management, said that the Duchess of Albany in July, 1911, laid the foundation-stone of the hospital, which contained two operating theatres—one for out-patients—a bacteriological and pathological department, X-ray room, museum, library, etc., and very large out-patients' rooms. Accommodation was provided for 24 beds, and they hoped that as the maintenance increased there would be a total of 40. The hospital had been completed without incurring debt, but more equipment was needed. They had spent £20,000. King Edward's Fund had contributed altogether £5,000, and the Zund Fund £3,000.

Vaccine Therapy at University College Hospital.

IT is announced that, owing to the generosity of Sir Harry Waechter in granting the sum of £300 for five years, University College Hospital will open a department for the treatment of disease by vaccine therapy.

Anderson's College Medical School, Glasgow.

THE following are the principal prizes awarded at the close of the session of Anderson's College Medical School, Glasgow:—

Anatomy.—Malcolm Kerr bursary—William Gordon, Russia, and William P. H. Lightbody, Glasgow, equal.

Physics.—Medical Section: Class medal, Norman S. Bruce, Glasgow; Dental Section: Class medal, Arnold J. Duncan, Newcastle-on-Tyne.

Zoology.—Medal, Miss Crawford, Glasgow.

Physiology.—Medal, George Christie Huntly.

Practical Physiology.—Medal, William Lightbody, Glasgow.

Materia Medica and Therapeutics.—Medal, Frederick W Thompson, Garliestown.

Dental Class.—Medal, William S. Murdoch, Garmouth, Morayshire.

Practical Pharmacy.—Medal, William Brown, Larkhall.

Practice of Medicine.—Medal, J. S. K. Boyd, Largs.

Operative Surgery.—Medal, Samuel Blyson, Glasgow.

Aural Surgery.—Medal, David Hardie, Leeds.

Diseases of Women.—Medal, J. Masson Greig and Douglas M'Alpine, equal.

University of Cambridge.

THE following degrees have been conferred:—

M.D.—J. W. Noble, Caius.

M.C.—L. Bromley, Caius.

M.B. and B.C.—E. L. K. Sargent and G. W. Spencer, St. John's; W. M. Oakden, Peterhouse; W. A. Pocock, Pembroke; J. Ll. M. Symns and J. B. A. Wigmore, Caius; A. B. Paul and A. S. Seabrooke, Christ's; E. Wordley, Emmanuel; R. Fisher and W. J. F. Symons, Sidney; J. F. Taylor, Selwyn.

B.C.—H. W. Comyn and E. S. Taylor, King's; K. B. Aikman, Clare; M. N. Perrin, Pembroke; M. Avent, Caius; J. R. Griffiths, Christ's.

University of Bristol.

AT the examination for the M.D. degree, Reginald S. S. Statham passed with honours. Emil Christoferson passed the final examination for the degrees of M.B. and Ch.B. Thomas S. Bradburn, Christopher C. C. Court and Percy Moxey passed the examination for the Diploma in Public Health. William R. Cooper and John R. Kay-Mouat passed Part I. of this examination. William H. Greet and Robert H. Turner passed the second examination for the degree of B.D.S.

University of Edinburgh.

AT the Graduation ceremony referred to in our last issue, the M.D. Degree was bestowed on the following:—Francis G. Bell, Oliver H. Blacklay, John F. Brown, John Brown-Lester, Leonard H. Bryson, William E. Bullock, B.Sc., Herbert M. Cargin, Walter D. Chambers, M.A., Noel A. Coward, John Cram, M.A., James Crocket, George H. Dart, Somerville B. Davis, Ian D. Dickson, John Drummond, William G. Evans, John Findlay, Arthur H. Firth, M.A., Ronald G. Gordon, B.Sc., Alexander G. M'P. Grant, Satis Chandra Sen Gupta, David K. Henderson, Harry F. Holmden, Thomas H. Horrax, Arthur J. G. Hunter, William D. Kirkwood, Robert A. Krause, William R. Logan, Donald M'Clintock, Frank B. Macdonald, Ranald Macdonald, George M'Mullan, John M. Macphail, Norman F. Mann, Benjamin B. Morgan, Robert F. Mudie, Harry G. G. Nelson, John J. H. Nelson, Hugh Paterson, John H. H. Pearson, Alfred A. W. Perie, Lieut.-Col. Kanta Prasad, I.M.S., Dorothy E. Pratt, Robert Proudfoot, George Raffan, George Richardson, George Y. Richardson, George H. W. Robertson, M.A., George M. Robertson, William A. Shafto, John J. M'I. Shaw, M.A., John I. Shepherd, M.A., Edgar W. Smerdon, Henry F. Smith, B.A., Willam R. Smith, B.Sc., Alexander Stuart, Bernard C. Tennent, Robert C. Walker, Willam G. Waugh, M.A., G. D. White, Frank M. Wilcox.

The Degree of Master of Surgery.—Kenneth Mackenzie, M.B., Ch.B., 1908 (with first-class honours), M.D., 1911 (Gold Medal for Thesis); Alexander P. Mitchell, M.B., Ch.B., 1907, M.D., 1909; Lancelot E. B. Ward., M.B., ChB., 1908 (with second-class honours).

Diploma in Tropical Medicine and Hygiene.—Alexander D. Stewart, M.B., Ch.B., Captain I.M.S.

Diploma in Psychiatry.—Percy W. P. Bedford, M.B., Ch.B., William Russell, M.B., Ch.B., Leslie H. Skene, M.B., Ch.B.

Royal College of Surgeons of Edinburgh.

THE following gentlemen, having passed the requisite examinations, on March 27th, 1913, were admitted Fellows of the College on Thursday last:—

Arthur I. Brown, M.D. C.M., William B. Brownlie, M.B., Ch.B.Glas., Charles Corben, M.R.C.S., L.R.C.P.Lond., M.D.Durh., Robert Crothers, L.R.C.P. and S.E., Ruston K. Dadachanji, L.M. and S.Bombay, M.R.C.S., L.R.C.P.Lond., John K. M. Dickie. M.D.Edin., Matthew R. Drennan, M.B., Ch.B.Edin., Edwin C. East, M.R.C.S., L.R.C.P. Lond., Max Greenberg, M.B., Ch.B.Edin., Francis J. Henry, M.B., Ch.B.Glasg., D.P.H.Camb., Frederick N. H. Maidment, M.R.C.S., L.R.C.P.Lond., M.B., Ch.B.Lond., Robert Massie, L.R.C.P. and S.E., Arthur S. Roe, M.R.C.S., L.R.C.P.Lond., M.B., Ch.B.Oxfd., Robert Stout, M.R.C.S., L.R.C.P.Lond., M.D.Lond., Alfred C. Talbot., M.B., C.M., M.R.C.S., L.R.C.P.Lond., John Watson, L.RC.P. and S.E.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow.

THE quarterly examinations of the above Board, held in Edinburgh, were concluded on the 19th inst., with the following results:—

The following candidates passed the first examination:—Donald McG. Stewart, John W. Irvine, John F. Campbell, and William F. C. Radford; and seven passed in Physics, three in Biology, and two in Chemistry.

The following candidates passed the second examination:—John F. Kerr, Thomas D. Renwick, William G. Anderson, Lizzie, O'Flynn, Alexander W. McGregor, James E. Ainsley, Edward A. Neilson, Maurice A. White, and Benjamin St. A. A. Young; and five passed in Anatomy and six in Physiology.

The following candidates passed the third examination:—Stewart N. Toulmin, William D. Bathgate, Leonard O. Weinman, Percy Chisholm, Thomas E. Lawson, Douglas C. M. Page, William O'Grady, Claude T. Darwent, John Berry, Harry L. Guthrie, Edgar Annequin, and Frederick A. V. Denning; and four passed in Pathology and three passed in Materia Medica.

The following candidates having passed the final examination were admitted L.R.C.P.E., L.R.C.S.E., L.R.F.P and S.G.:—George W. Fleming, Stanley E. Jones, Harry G. Hankins, William Murphy, John M. Milne, Charles H. N. Baker, Charles C. Forsyth, Cameron V. Bailey, James B. Donaldson, Stuart MacV. Fisher, Frederick G. Gibbs, John E. L. Keys, Frederick R. Lucas, James R. Menzies, William A. Rees, Ian C. Mackenzie, Charles Cosgrove, and Roy D. Clayton; and two passed in Medicine, three in Surgery, two in Midwifery, and ten in Medical Jurisprudence.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

(a) A paper read before the Section of Surgery, Royal Academy

Reprints.—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Mr. P. C. P. Gerrard.—Your communication was received too late for insertion. As we go to press on Tuesday morning only letters can be attended to that reach us by first post.

Dr. O'Hara (Melbourne).—The suggested notes on leading events in the Antipodes will be thankfully received and will doubtless be read with interest in the mother country.

Tropical (Liverpool).—Our opinion of Castellani and Chalmers, to which you refer, will be found on reference to the page devoted to "Reviews of Books" in our present issue.

Dr. Dowler (Mussoorie, India) is thanked for his communication.

Dr. S. T. (Yorks).—Typhoid fever was responsible for 196 deaths in London in 1910, 181 in Paris, 584 in St. Petersburg, 73 in Berlin, 82 in Vienna, 330 in Calcutta, 558 in New York, and 195 in Buenos Ayres. The death rate per thousand was 0.05 of the population in the towns of England and Wales.

FOURTH INTERNATIONAL CONGRESS ON SCHOOL HYGIENE.

The fourth International Congress on School Hygiene, and the first to be held in America, will take place at Buffalo on August 25th-30th. The programme will consist of 250 papers and 15 symposiums, taking up hygiene from all points of view. The congress is open to all persons interested in school hygiene upon the payment of a fee of $5. Application for membership should be sent to Dr. Thomas A. Storey, College of the City of New York, New York City. President Wilson has accepted the honorary office of patron of the congress. The president of the congress is Mr. Charles W. Eliot, of Harvard University. The vice-presidents are Dr. William H. Welch, of Johns Hopkins University, and Dr. Henry P. Walcott, President of the recent International Congress on Hygiene and Demography, and Chairman of the Massachusetts State Board of Health. The President of the Organising Committee for Great Britain and Ireland is Sir Lauder Brunton, and among the vice-presidents are Lord Sheffield, Mr. C. H. Hobhouse, Lord Belper, Sir Edward Brabrook, Sir Edward Byers, Sir John Cockburn, Sir William Collins, Sir Henry Craik, Sir James Crichton-Browne, Sir George Fordham, Sir Henry Hibbert, Sir William Mather, Sir Shirley F. Murphy, Sir Robert Morant, Sir George Newman, Sir Harry Reichel, Sir John Struthers and Sir Aston Webb.

Dr. W. J. M. (Bournemouth) is thanked for his letter with enclosure.

Mr. R. Kelly (Canterbury).—According to Dr. W. H. R. Rivers, tobacco comes out from the ergographic test less creditably than other drugs, such as alcohol, cocaine and strychnine. Trainers are right, therefore, in prohibiting the use of tobacco while preparing for any feat involving severe muscular effort.

F.R.C.S.Edin. (Reading).—The various muscular phenomena met with in the early stages of phthisis were well described by Pottenger in 1909, who believed that muscular spasm results from the reflex excitation of the spinal segments by afferent stimuli from the lung through the sympathetic nervous system to the cord, thereby exciting neighbouring centres in the anterior horns, with consequent spasm.

Nil Desperandum (Herts).—The principal pharmacological action of the leaves of the *Viola odorata* is that of a laxative and mild urinary antiseptic. The active principle of the root is emetic and cathartic. The plant is certainly harmless, but as to its efficacy in cancer the evidences are that the treatment has afforded slight relief, but not cure.

Appointments.

Barber, H. W., M.B.Cantab., Medical Registrar to Guy's Hospital.

Barnes, H. Patricia, M.B., B.S.Lond., House Physician at the East Suffolk and Ipswich Hospital.

Cleminson, F. J., M.C.Camb., F.R.C.S., Assistant to the Ear and Throat Department at University College Hospital.

Davies, J. L., M.B., B.S., House Surgeon at University College Hospital.

Doran, S. S., L.D.S.R.C.S.Eng., Lecturer in Dental Surgery and Pathology in the University of Manchester.

Douglas, J. S. C., D.M.Oxon., Lecturer in Pathology in the University of Manchester.

Gardiner, H., M.B., B.S.Lond., Anæsthetist to Guy's Hospital.

Heaton, T. B., M.B.Oxon., Medical Registrar to Guy's Hospital.

McNair, A. J., M.R.C.S., L.R.C.P.Lond., Anæsthetist and Obstetric Registrar to Guy's Hospital.

Poulton, E. P., M.B.Oxon., M.R.C.P.Lond., Medical Registrar to Guy's Hospital.

Rees, F. H., M.B., B.S.Lond., House Surgeon at University College Hospital.

Saner, J. G., B.C.Cantab., Resident Surgical Officer to Guy's Hospital.

Vacancies.

Royal Victoria Eye and Ear Hospital, Dublin.—House Surgeon. Salary £40 per annum, with board and residence. Applications to the Secretary. (See advt.)

Monaghan District Lunatic Asylum.—Junior Assistant Medical Officer. Salary £100 per annum, increasing by yearly increments of £10 until it reaches £150 per annum, with furnished apartments, etc. Applications to J. P. Conlon, Resident Medical Superintendent. (See advt.)

Three Counties Asylum, near Hitchin.—Junior Assistant Medical Officer. Salary £200 per annum, with board, furnished apartments, washing, and attendance. Applications to the Medical Superintendent.

Kent County Asylum, Chartham, near Canterbury.—Junior Assistant Medical Officer. Salary £220 per annum, with furnished apartments, including lighting, heating, and attendance, also laundry, milk, and garden produce. Applications to Medical Superintendent.

Kent County Asylum, Maidstone.—Fourth Assistant Medical Officer. Salary £200 per annum, with furnished quarters, attendance, coals, gas, garden produce, milk, and washing. Applications to Medical Superintendent, Asylum, Maidstone.

Hereford County and City Asylum.—Assistant Medical Officer. Salary £155 per annum, all found. Applications to the Medical Superintendent, The Asylum, Burghill, Hereford.

Leicestershire and Rutland Lunatic Asylum, Narborough, near Leicester.—Junior Assistant Medical Officer. Salary £200 per annum, with furnished apartments, board, and washing. Applications to W. J. Freer, Esq., Clerk to the Committee, 10 New Street, Leicester.

Canterbury Mental Hospital, Canterbury.—Assistant Medical Officer. Salary £160 per annum, with board, lodging, washing, and attendance. Applications to the Medical Superintendent.

University of Durham College of Medicine, Newcastle-upon-Tyne. —Demonstrator of Anatomy. Salary £200 per annum. Applications to Professor Howden.

City of Birmingham.—Salterley Grange Sanatorium for Consumption, near Cheltenham.—Resident Medical Officer. Salary £300 per annum, with board, etc. Applications to Robertson, Council House, Birmingham.

Carlisle Dispensary.—Resident Medical Officer. Salary £150 per annum, with apartments (not board). Applications to the Hon. Secretary, Mr. G. A. Lightfoot, 23 Castle Street, Carlisle.

Births.

Cane.—On July 19th, at Kirkee, near Poona, India, the wife of Captain Arthur S. Cane, R.A.M.C., of a son.

Corbett.—On July 5th, at Kasauli, India, the wife of Captain D. M. Corbett, R.A.M.C., of a son.

Deane.—On July 14th, at Wragby, Lincolnshire, to Dr. and Mrs. Wm. Deane—a daughter.

Gillespie.—On July 13th, at Dunkeld, King's Road, Knock, Belfast, to Dr. J. R. and Mrs. Gillespie—a daughter.

Harris.—On July 13th, at 98 Lower Addiscombe Road, Croydon, to Dr. and Mrs. Poulett Harris—a daughter.

Hunt.—On July 18th, at 3 Goldsmid Road, Brighton, the wife of Ernest Rivaz Hunt, M.A., M.D.Cantab., of a son.

Marriages.

Cheadle—Reynolds.—On July 17th, at St. Mary Abbott's, Kensington, Bernard Arthur Cheadle, M.B., B.S.Lond., of Salisbury, Rhodesia, son of the late Rev. J. H. Cheadle, Canon of Westminster, and of Mrs. Cheadle, 11 Campden House Road, Kensington, to Edith Francis, widow of Claude Reynolds, late of Bulawayo, Rhodesia, daughter of the late John Evans, of Stamford Hill, N., and of Knightrider Street, E.C.

Psimenos—Scanes Spicer.—On July 17th, at the Church of the Hagia Sophia, St. Petersburg Place, London, W., by special licence, and with the full sacramental rite of the Holy Greek Church, and afterwards at St. George's, Hanover Square, George John, son of Mr. and Mrs. Psimenos, of Pyrgos, Ilidos, Greece, to Maud Mary Bullen (Dornie), daughter of Dr. Robert Hy. Scanes Spicer, Consulting Throat Surgeon, St. Mary's Hospital, London, W., and Mrs. Scanes Spicer, of 28 Welbeck Street, Cavendish Square, W., and Lynmead, Carlisle Road, Eastbourne.

Downer—Beebe.—On July 17th, at Christ Church, Westminster, Reginald Lionel Ernest Downer, M.D.Lond., of The Firs, Matlock, son of Mr. W. J. Downer, C.B., C.M.G., I.S.O., J.P., and Mrs. Downer, of Newlands, Woking, and Daphne Marguerite, second daughter of Mr. and Mrs. A. Hatton Beebe, of Elvaston, Woking.

Deaths.

Gotch.—On July 15th, at 12 St. Mary Abbott's Terrace, Kensington, two days after his 60th birthday, Francis Gotch, M.A., D.Sc., F.R.S., Waynflete, Professor of Physiology in the University of Oxford, son of the late Rev. Dr. Gotch, of Bristol.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, JULY 30, 1913. No. 5.

NOTES AND COMMENTS.

The Brighton Meeting of the B.M.A.

THE eighty-first annual meeting of the British Medical Association has come and gone. Brightonians have been dosed for a week with things medical, and both the inhabitants and the visitors have been treated to such a display of rhetoric and robes—not to mention rockets—as they are not likely to forget. From the purely professional standpoint, the discussions and papers read in the Sections have been full of interest. Despite the absence of any Cabinet Minister at the Section of Medical Sociology, the meetings held thereat were so numerously attended that admission could only be obtained by showing a special invitation card or the member's ticket. As it was, many distinguished laymen were present at the meetings of this Section, while at a meeting of the State Medical Service Association Mr. Bernard Shaw's grim remarks anent the practice of medicine were fully characteristic of that speaker's philosophy. Socially the gathering was a huge success, for the members were regularly surfeited with entertainments and hospitality. For these reasons the Brighton meeting will remain a memorable one in the history of the Association.

A Large Increase in the B.M.A. Subscription.

THE annual representative meeting of the British Medical Association has been fraught with weighty decisions. Not least amongst them is the resolve to raise members' subscription from twenty-five shillings to two pounds. The reasons for this step may reasonably be assumed to lie in the strain upon funds caused by the recent loss of members owing to differences over the insurance policy, and by the large amount spent in fighting the Insurance Act. It remains to be seen whether the proposed increase will meet the approval of the main body of the Association, for the matter can only be finally settled by a reference to Divisions. When the subscription was raised, some years ago, from a guinea to twenty-five shillings, a good deal of dissatisfaction was expressed in some quarters. Our own view is that it would be infinitely wiser to make a serious attempt to cut down expenditure rather than to increase income by a levy upon members. The financial affairs of the whole Association might well be the subject of careful expert investigation, especially as regards the journal. Were the latter in the hands of a private business firm, it would probably show a far larger margin of profit than it does under present management. As to the increase of subscriptions, although a few members will pay it with alacrity, it will press somewhat unfairly on some of the less prosperous members of the Association; and the project is, in any case, hardly calculated to add to the popularity of that important body.

What Does It Mean?

THOSE who have recently joined the Association have done so on the unwritten understanding that the annual subscription of twenty-five shillings would remain permanently fixed at that sum. The raising of the amount from one guinea to twenty-five shillings some years ago was strongly resented by some who had paid the smaller sum for many years past. If there be a matter that above all things should be determined by direct appeal to members, it is that of the payments they are called upon to make towards the funds of their organisation. The result of an appeal to Divisions will be awaited with a good deal of interest. If the recommendation of the Representatives be thrown out, it will prove once more emphatically that they are hopelessly out of touch with the electorate they are supposed to represent. It seems somewhat strange that such a proposal should be discussed and settled without some previous attempt to learn the views of members upon so vital a point. When the constitution of the Association is revised, as it must assuredly be at some time or other, it is to be hoped that some means of referendum to members upon important matters will be included in the reforms.

Medicine and the Public.

FROM the point of view of the man in the street the annual meeting of the B.M.A. affords a capital opportunity for obtaining free medical advice. The columns of the lay Press devote considerable space to reporting the proceedings, and any medical pronouncement that is considered by the "eminent Harley Street physician" of Fleet Street as likely to afford good copy is eagerly seized upon and "written up" for the special benefit of the public. During the dull season that is fast approaching there could hardly be found more appropriate subjects for discussion in the correspondence columns of the daily papers than those of sea-bathing, sleep, the ravages of some new disease, etc. And so the higher (medical) education of the public is advanced. What does it signify if the names of the readers of papers at the sectional meetings appear in the brief abstracts in the papers? No one raises any objection on ethical grounds to this form of self-advertisement, for if the three great addresses are reported in the lay Press, there is no reason why other equally attractive papers, though delivered before smaller audiences, should not also be mentioned, provided they are sufficiently interesting from the public point of view. It is far better that the masses should obtain crumbs of medical information from a reliable source than whole loaves of pseudo-medical twaddle delivered straight from the bakehouses of quackery and charlatanism.

The Eastbourne Excursion.

A special note may be added as to the Eastbourne excursion on Saturday last, which was one of the best organised affairs of the kind that the writer can recall after many years' experience of similar pleasure jaunts. The party was restricted to about eighty, and tickets were applied for several times over by members at Brighton. The party were received at Eastbourne by the Mayor—Mr. C. W. Bolton—and the Mayoress. A sumptuous luncheon was given at the Town Hall by the Corporation, and many leading citizens were present. In the afternoon the visitors were taken for a drive through lovely country to Beachy Head, whence they returned to the town, and at 7.30 were entertained to dinner by the members of the local Division at Devonshire Park. Among the after-dinner speakers were the Mayor, the President of the Association, Dr. W. Ainslie Hollis, and the Chairman of the Council, Dr. Macdonald. A concert followed, with fireworks in the Park, and the visitors returned late at night to Brighton by special train. The way in which all details of this charming excursion were managed reflects the greatest credit upon the kindliness and tactful experience of the local medical men and the Corporation. The Medical Secretary of the Association, Dr. Alfred Cox, was present, and Dr. Parry, of Brighton (local Honorary Secretary), was prominent throughout the day's proceedings.

Alleged "Bad Air" in an Underground "Tube" Railway.

Last week an inquest was held upon the body of a man, aged 58 years, who was found dead upon the platform of a "Tube" station. The evidence showed that deceased was in the habit of standing on the platform and allowing a number of trains to pass by before he boarded one. The interesting point is that a medical man who was called to deceased and who tried to restore him by artificial respiration, attributed death to a combination of causes, amongst which was the bad air of the tube. As this statement is of public importance, it is interesting to inquire on what grounds it was based. Witness stated in the newspaper report of the inquest himself to have felt the ill effects of the air when attending to the man at the station. He had no analysis of the air to uphold that view. Not long after the first "tube" railway was started in London, many complaints were made about the ventilation, and scientific tests showed the desirability of a better system for the circulation of air, which we believe has subsequently been adopted in all our London "tubes." On the whole, there appears to have been little ground for attributing the death of deceased to the bad quality of the underground air. As a matter of fact, moreover, the fact that deceased was in the habit of letting several trains pass unnecessarily raises a strong assumption of something seriously abnormal in the state of his brain. In dealing with an occurrence so definite and circumstantial as that of carbonic acid poisoning, it is well for a member of a learned profession to avoid advancing vague surmises, in support of which he is unable to produce a shred of proof.

Capt. R. Markham Carter, I.M.S., has been appointed by H.E. the Governor of Bombay to officiate as Professor of Pathology at the Grant Medical College, Bombay, in succession to Major E. F. G. Tucker.

LEADING ARTICLES.

THE ADDRESS IN MEDICINE AT THE BRIGHTON MEETING OF THE B.M.A.

The annual address in medicine at the meeting of the British Medical Association was last week delivered by Professor George R. Murray. The title chosen was "Some Aspects of Internal Secretion in Disease," a subject with which he was particularly able to deal. Although there was nothing strikingly new in his remarks they nevertheless formed a notable summary of the present position of one of the most important branches of modern medical research. It is probable, indeed, that we are on the verge of still greater discoveries than those which have been hitherto made, or—as the lecturer remarked—it was gradually being learnt that many diseases were due to the failure or perversion of normal chemical processes in which the ductless glands played an important part. The marvellous page of modern medicine unfolded by our discovery of the source of the functions of those particular glands was well illustrated in the course of the address. Dr. Murray described as a practical physician the peculiar forms of disease associated with such glands as the thyroid, the pituitary and the suprarenal glands, and the extent to which it was possible to relieve them by administering gland extracts derived from other sources. Referring to the effects of hyperthyroidism, he pointed out that we were still anxiously awaiting an explanation of that morbid activity, which came on sometimes rapidly, sometimes slowly, persisting it might be for a few months or continuing unabated for years. If the cause of this characteristic change in the thyroid gland were known we should be obviously in a much better position to treat the disease in a rational manner. Incidentally we may interpolate that the investigation of this important point, fraught with so much weal or woe to humanity, should be taken up by the State in the interests of the citizen. As Dr. Murray remarked, it was now fully recognised that the ductless glands had important relationships to each other, and that the secretion of one gland might either stimulate or inhibit the activity of other glands. As regards the pancreas, he stated that the gap to be bridged in order to enable us to make use of the present knowledge of the functions of the pancreas appeared to be a narrow one. If only the normal pancreatic hormones could be transferred directly without change from a healthy animal into the blood stream of a case of pancreatic diabetes, striking therapeutic results might reasonably be expected. The opinion has been cherished for some time by various investigators that the future hope in the curative treatment of diabetes lies by way of internal gland secretion. Clinical medicine, as the lecturer concluded, had already gained enormously from results obtained by experimental pathology, and we might look to the future with confidence for still further advances which would place more simple and efficient methods of treatment within our reach. The address may be commended to medical men who wish a careful and authoritative account of an important branch of medical activity.

THE ADDRESS IN SURGERY AT THE BRIGHTON MEETING OF THE B.M.A.

The friendly rivalry that exists between the pseudo-antagonistic branches of therapeutics, medicine and surgery, has long been a source of amusement to those who are unable to discern the essence of the distinction between the two great divisions of medical practice. So gradually, indeed, has surgery encroached upon the domains of pure medicine, so-called, and so subtle has been the intrusion of the surgeon's knife into regions of the human frame hitherto regarded as quite beyond its reach, that now scarcely a nook or cranny of our physical being remains unexplored by the cold steel of the twentieth-century operator. Is medicine the loser? one is tempted to ask, from this apparent curtailment of what has, up to the present, been regarded as its legitimate sphere of work. The answer is to be found in the substance of the Address in Surgery delivered at the Brighton Meeting of the British Medical Association by Sir Berkeley Moynihan, who endeavoured to show that opportunities have been abundantly afforded in recent years for demonstrating the power of surgical research to enlarge the scope and to enrich the knowledge of many of the problems of internal medicine. By a careful study of the "pathology of the living," Sir Berkeley Moynihan is of the opinion that a profound change has by degrees crept over our knowledge of almost every form of chronic abdominal disorder. *Post-mortem* statistics, valuable though they are, cannot afford anything like such important information respecting, say, the condition of the vermiform appendix during a patient's life as an exploratory operation conducted under the most modern and approved *technique*. It is not a little remarkable that conditions of the abdominal organs other than those which require immediate attention are frequently found to exist, particularly in cases where one of them is the centre of some infective or suppurative process. The older and more conservative plan of expectant treatment of abdominal diseases was often disastrous in its effects, whereas nowadays, owing to the introduction of simpler methods and more rapid operating, it is possible not only to reduce shock to an almost negligible quantity, but also to remove the source of the trouble at a much earlier date. With the increase in the number of gastric operations surgeons have found that many patients who complained of symptoms leading to the clinical diagnosis of gastric ulcer were found, when laparotomy was performed, not to be suffering from any ulceration of the stomach, neither were they relieved by gastro-enterostomy. In these cases the organ at fault has been found to be the appendix, lesions of which appear to favour the development of a gastric ulcer. The records of the Mayo clinic show that in 71 per cent. of cases of cancer of the stomach the malignant process is engrafted upon a simple one. If the appendix is to be held responsible for cases of chronic gastric and duodenal ulcer, it may, logically, be charged with favouring the production of cancer. Sir Arbuthnot Lane takes the wider view that the intestine itself is the factory where poisons are elaborated. The debt which medicine owes to surgery is well illustrated by discovery of the dependence of morbid conditions of the stomach and duodenum upon some infective focus resident in the appendix. Physicians will be less and less content in the future to acquiesce in a diagnosis of chronic dyspepsia without giving the patient the benefit of a surgical exploration, the mortality of which may now be reckoned as practically *nil*. In disorders of the pancreas it must be admitted that comparatively little was known about their pathology until surgeons investigated the subject. There is no reason why medicine, in its quest for knowledge, should hesitate to accept the gifts that surgery is able to offer, for the experimental method of investigation of disease in the living subject is acknowledged to be best, and, according to Sir Berkeley Moynihan, no experiments can claim an equal rank with those which form a part of almost all surgical procedures. Working upon these lines, it is at least reasonable to assume that a still greater advance will be made in the future by surgery in the direction of the elucidation of some of the obscure problems of medicine.

CURRENT TOPICS.

The New King's College Hospital.

The opening of the extensive new buildings of King's College at Denmark Hill, Camberwell, by the King and Queen last Saturday signalises the last stage in the transference of the old " King's " from its sequestered site near Lincoln's Inn Fields. After the reception of purses in the out-patients' waiting hall by the Queen in aid of the building fund, His Majesty declared the building open in the presence of a large assembly of guests. Among many features of special interest contained in the new buildings may be mentioned an observation ward, where doubtful cases may be watched for a time before being admitted to their proper wards. This ward contains eight beds, each in a separate glass-screened cubicle, by means of which patients suspected of being in the developmental stage of infectious diseases may be suitably observed. The heating apparatus is of the latest and most approved type, the total length of pipes employed for the purpose being twenty miles. The electric power is generated by Diesel oil engines, and there are over two miles of electric mains and sub-mains. The ice plant is equal to the manufacture of ten tons of ice per day. The staff and management of the new buildings may be congratulated upon the possession of an institution so well equipped to treat disease as the fine block now ready for the reception of patients at Denmark Hill.

Sea Bathing and Health.

At this season of the year, when our sea coast resorts are crowded with holiday makers, it was most opportune that a discussion on the subject of sea bathing should have taken place at the Section of Climatology and Balneology at the annual meeting of the British Medical Association at Brighton. The fame of that watering-place, as the President pointed out in his Address, was largely based upon the virtue of its sea bathing, which sport was greatly popularised by Dr. Russel. It is well known that people do not take cold after bathing in the sea as after fresh water bathing. The temperature of sea water is affected by its saline constituents and is more equable than that of river water, hence bathing therein can be indulged in for a longer period and with greater safety than in fresh water. One of the speakers, Dr. W. D. Johns, of Bournemouth, dwelt upon the value of sea bathing for consumptives, and consequently struck a popular note. If suitable cases were selected the risk was practically *nil*, while the benefits were very great. The restrictions are really few; only quiescent or arrested cases are chosen, and of these swimmers are encouraged to swim on the back in preference to employing the breast stroke. Non-swimmers are not encouraged to learn to swim. Immediately after the bath hot milk is taken, followed by a short walk. This latter piece of advice may be recommended for all. It is a great mistake to bathe after a heavy meal or to remain in the water if chilliness ensue. Young children should not be forced to enter the water against their will. Weakly patients had far better have a quiet brine bath under medical direction. For ordinary folk who are simply run down there is no better tonic than a dip in the briny every morning before or after breakfast.

The Prevention of Epidemic Diarrhœa among Infants.

Whether the prevalence of epidemic gastro-enteritis in infants during summer weather be due to the influence of flies, stone-fruit, bad milk, or other factors may yet remain debatable; nevertheless all are agreed that no stone should be left unturned in order to prevent the occurrence of such disease. The Local Government Board, with laudable promptitude, have recently issued a circular to sanitary authorities in England and Wales reminding them of the importance of taking all practicable measures for the prevention of epidemic diarrhœa and other infectious diseases of infants. Among other things, the Board emphasise the value of systematic visitation of the homes of infants under the direction of the Medical Officer of Health. As such visit should be made as early as possible, authorities are recommended, where they have not already done so, to adopt the Notification of Births Act. It is explained that although local authorities are not specifically empowered to appoint officers for the execution of this Act, it is their duty to appoint the officers necessary for the execution of the Public Health Act, and the Board consider that they may properly employ and pay women to give advice with the object of preventing infectious diseases of infancy, including those arising from improper feeding. Where there is insufficient work to employ the whole time of a woman in this capacity the office may be joined with that of Assistant Inspector of Nuisances, Tuberculosis Visitor, or school nurse. In considering the question of adopting the Act for districts other than county boroughs, the Board suggest that the local authorities before taking any formal proceedings should ascertain from the County Council whether they contemplate the adoption of the Act for the county or for some of the county districts with a view to conferring with the County Council with regard to a scheme for the adoption and administration of the Act. Reference is made to the excellent voluntary work done by infant consultations, health societies, and similar associations, which it is suggested the Medical Officer of Health should co-ordinate with the work of his department.

The Things We Say.

The spirit of breezy confidence of the Western Press in matters medical helps us to hear ourselves as others hear us. Our calling has a full and complete technical vocabulary comparable to that of golf, but we never knew till the *Journal of the American Medical Association* printed some extracts how unintelligibly mysterious our conversation was. The Trendelenberg position is described by the *Philadelphia Ledger:* "It consists simply of posterior operations by means of a specially contrived operating table that in cases of a particularly delicate character have been remarkably successful." Again: "The V— Pharmacy has been named as a supply station for antitoxin. The antitoxin will be used in cases of diphtheria, to prevent blindness in newly born babies, for throat cultures and in the examination of blood in typhoid and malaria cases." The *Boston Record* says: "The B. Welchi is the gas bacillus dwelling in the international track." Reports of medical meetings refer to "chronic intestinal nephritis," "hydrated mole," "perpetual eclampsia," and "an aneurism of the order A." Verily, speech was given to some people to conceal their thoughts.

The Decline in Child Mortality.

That a striking decline in infant and child mortality has taken place throughout the country is a gratifying fact gathered from a report by Dr. Arthur Newsholme recently issued by the Local Government Board. The great saving of child life which has undoubtedly been effected within the last few years is to be attributed, not merely to favourable climatic conditions, but to improved sanitary and housing conditions, more efficient municipal and domestic cleanliness, education in hygiene, increased sobriety of the population, and the widespread awakening to the national importance of child mortality. It is well known, the report states, that after a long series of years, during which no appreciable sustained improvement occurred, a great decline in infant mortality has been experienced in recent years. In seven years, 1906-12, 736,682 infants under one died in England and Wales, the average annual death-rate being 115 per 1,000 births. Had the infantile death-rate been 144 per 1,000 births, the average rate for the seven years 1899-1905, then 922,454 infants would have died in the seven years 1906-12. The improved conditions have implied a saving of 185,772 lives of infants during these seven years. Dr. Newsholme demonstrates that the rate of infant mortality in the towns of a given geographical county shows no parallelism with the proportion of the total population which is aggregated in the towns of that county, and that towns within the same county, sometimes within a few miles of each other, show widely divergent infant mortality rates. It is also shown that the size of a town has no definite relationship to excessive infant mortality. Dealing with some of the special conditions associated with high infant mortality, Dr. Newsholme lays stress on the important bearing of defective sanitation on the question. He also refers to the ignorance of mothers as to child hygiene, and as to satisfactory methods of rearing children under the adverse conditions of town life, which is, he believes, an important factor in producing excessive infant mortality in the more densely populated urban areas. Instruction in the matter of feeding, clothing, and general hygiene is badly needed; and the results obtained where the modern methods of child welfare work have been adopted show that such instruction has marked influence in improving the health of infants. Unsatisfactory storage of food is a further source of trouble, more especially in the summer months. Another important factor, it is pointed out, is the industrial employment of women, which may cause child neglect and produce increased infant mortality. As regards the relation of poverty to excessive mortality, he points out that infant mortality is low among the well-to-do, and that poverty is a direct cause where it induces malnutrition of mother or infant. Moreover, poverty is not infrequently associated with ignorance and carelessness, and with these commonly go overcrowding and uncleanliness.

Insurance Committees in Ireland.

Insurance committees in Ireland are like snakes in Iceland—there are none. The provisional committees appointed twelve months ago came to an end on July 15th, 1913, and up to the time of writing no committees have been appointed to take their place. The representatives of local authorities and the nominees of the Commissioners are to continue in office, but the societies were now for the first time to exercise their right of appointing members. As long ago as May 20th, the Commissioners issued elaborate regulations governing the method to be adopted in the election of representatives of insured persons. They were so planned that the elections should be completed, and the committees ready to take up office by July 15th. The arrangements, however, appear to have broken down, and no committees have as yet been appointed. The chief result of this failure is that the sanatorium benefit is suspended so far as the consideration of new applications is concerned. No consumptive can at present claim this benefit to which he is by law entitled. The position—if it were not so serious—would be amusing to those who remember the blood-curdling threats held over the head of at least one insurance committee in Ireland by the Commissioners, if the committee should fail to carry out in every particular the mandates of the Commissioners. For the past three weeks, owing to the failure of the Commissioners to make effective arrangements for the appointment of new committees, the sanatorium benefit has been at a standstill.

The Cultivation of Medicinal Plants.

It has long been known that crude drugs are subject to considerable variations in activity as regards their active ingredients. Were it possible to establish "physic gardens," such as those at Chelsea, in places where the specimens grown would be under skilled supervision, the results of such "farming" would prove interesting alike to the prescriber and to the pharmacist. The science of the cultivation of medicinal plants may be said to have received an impetus from the garden known as the "Materia Medica Farm," which has been established for some years past upon a site close to the "Wellcome" Chemical Works at Dartford. Such plants as digitalis, which is an exceedingly important crop, are grown here under conditions which, it is claimed, ensure that such slight variations in character as occur in the leaves used in the preparation of the concentrated tincture of digitalis have been reduced to what is necessarily due to the variations of season from year to year. Errors due to the inclusion of faulty or untrue specimens, frequently to be found in the collections made by both amateur and professional herb gatherers among the wild plants, are here completely eliminated. In connection with belladonna, an extended series of experiments has been carried out, such as treating it with different manures and shading it during growth with coloured fabrics. And so in like manner are many other herbs tested and experimented with over considerable tracts of land. A number of plots are used for purely experimental crops as distinct from the staples. One may find the meadow saffron growing there, close by French roses, lavender, and peppermint, together with senega and ginseng, whose root plays so important a part in Chinese medicine. The farm affords all sorts of conditions, from shady to sunny, as may be required for the different plants, so that only the best drugs are obtainable from such a source.

PERSONAL.

H.H. the King has been graciously pleased to approve of the Polar Medal with clasp, inscribed "Antarctic, 1910-1913," being granted to the following members of the medical profession who served in the British Antarctic Expedition, 1910-1913:—Surgeon George Murray Levick, R.N.; Surgeon Edward Leicester Atkinson, R.N.; Assistant-Paymaster Francis Randall Hugo Drake, R.N.; and Edward Adrian Wilson, M.A., M.B. (deceased) (clasp only).

Mr. Langdon Fuller Hanbury, M.R.C.S., has been appointed Medical Superintendent of the West Ham Borough Asylum, Ilford.

Dr. J. B. Tighe, M.B., B.Ch., B.A.O.Irel., has been appointed Medical Superintendent of the Gateshead Asylum, Stannington, Northumberland.

Mr. William Leonard Brandon, F.R.C.S, has been awarded the Stewart Prize of £50 by the British Medical Association for his researches into the epidemiology of beri-beri.

It has been decided to invite public subscriptions in order to endow a child's cot at the Royal South Hants and Southampton Hospital in memory of the late Dr. J. L. Thomas.

Dr. T. Shadick Higgins, Assistant Medical Officer of Health for Birmingham, has been appointed Medical Officer of Health for St. Pancras, in succession to the late Dr. Sykes.

Dr. George Pernet, M.D.Paris, M.R.C.S., L.R.C.P., has been appointed Dermatologist to the West London Hospital, and Lecturer in Dermatology to the West London Post-Graduate College.

Dr. J. A. MacDonald, LL.D., M.D., of Taunton, the Chairman of the Council of the British Medical Association, has been awarded the Gold Medal of the Association for conspicuous services rendered thereto.

At a reception given by Dr. and Mrs. Tunnicliffe last week, a gold watch and chain was presented to Dr. Linnell, Medical Superintendent of the Mount Vernon Hospital, by the staff, chaplains, residents, nursing staff, and household of the hospital.

Dr. H. R. Renwood, M.B., D.P.H., F.R.S.E., has been appointed Professor, and Dr. J. Sherwood New, M.B., B.S., D.P.H., Assistant and Lecturer, in the Department of Hygiene and Sanitation at the new University of London School of Architecture at University College.

CLINICAL LECTURE
ON
PUERPERAL ECLAMPSIA AND ITS TREATMENT.

By Prof. J. VEIT, M.D.

[Specially Reported for this Journal.]

The poison of eclampsia comes from the albumen of the periphery of the placenta.

This will shortly be the view that is generally accepted. One of the methods by which I would wish to bring about its acceptance was the attempt to secure the diagnosis of pregnancy by examination of the blood of the pregnant woman. In every human pregnancy the villi dip into the blood of the intravillous interspaces. If the poison of eclampsia therefore comes from the periphery of the villi and reaches the maternal blood in the intervillous spaces, then in every pregnancy something must reach the blood from the villi and this something must set up changes that bear some relation to the eclamptic poison.

During the last ten years especially a great deal of diligence and sharp-sightedness have been employed in the examination of the blood of pregnant women, and a consideration of the genesis of eclampsia has always played a part in these investigations. We already spoke of the toxicoses of pregnancy and the like. Then came the serodiagnosis of pregnancy; not as I at first thought on the basis of Ehrlich's antibodies or precipitines, but through the optical method of Abderhalden, and this insight into the physiology of pregnancy was materially enlarged by his chemical reactions.

But this proof is not associated with the dipping of the villi into the blood. In animals in which the villi are only connected with the uterus by the glands, the serum diagnosis is also in agreement. In spite of this we gain a great deal in the understanding of eclampsia, for eclamptic convulsions in labour only occur in the human female, and besides the human subject the villi are not met with in comparative anatomy except in the hedgehog and the tarsus spectrum as dipping into the maternal blood, so that the assumption of the origination of eclampsia from the albumen of the villi still stands; it even gains power, as only this dipping into the blood can explain the fact that without any trauma a very strong exacerbation follows so strong that all the protective powers of the body are powerless against it.

Such theoretical conclusions are made use of as the foundation of our treatment of the disease. As eclampsia is an intoxication there must be a counter poison, an antidote. At present we are not enough acquainted with it to already have a sufficiency of observations on the subject.

But until we do know it, cases of eclampsia must still be treated successfully. Whoever works on this subject in addition to practical measures seeks to find out a theoretical basis for his proposals, and as there is no great certainty as to where the poison is to be located, many of the therapeutical measures are directed against one symptom only, which epicritically may be considered rather a consequence and not an essential part of the intoxication. So therefore many of the measures of treatment proposed do not meet with much acceptance, as they are based on a false theory as to ætiology, or are directed against a morbid change which is only a consequence, and not itself an essential part of the disease.

But the circumstance that such measures are proposed on an uncertain basis shows the difficulty we lie under as regards treatment. If no results had followed amputation of the breast or trephining, such proposals would never have been made known, and if good results were seen, or supposed to be seen, it was only because the prognosis in eclampsia was so difficult to determine. Many cases recover, and when we believe that they recover through the treatment, we must believe that they recovered through the particular treatment made use of in the particular case.

The curative measures now generally employed in eclampsia are to find their justification on both theoretical and practical grounds. Theoretically the removal of the source of the poison, viz., the placenta, rapid delivery, the chief effect of the poison, the convulsions, therefore their removal by narcosis, "unpoisoning" of the blood by partial removal of it, venesection with or without saline infusions.

Statistics should afford the practical demonstration. Of these three methods which to-day are worthy of recommendation, that which stands on the best foundation is rapid delivery; as the poison is furnished by the placenta, complete clearing out of the uterus is the first step. Only something that was in the body before can now do harm, and it must be removed.

In recent times Halbertsma has expressed the opinion that the patients must be delivered as speedily as possible, as with the termination of the pregnancy the convulsions also cease. But abdominal Cæsarean section was at that time more dangerous than it is now, and the result was that only a few followed the recommendation. The great majority of men declined abdominal Cæsarean section for that reason, and the result was not very different when Dührsenn proposed vaginal Cæsarean section for eclampsia. Incision of the vagina and cutting through of both anterior and posterior walls of the uterus without regard to opening of the peritoneum did not commend itself to the mind of the obstetrician. The means seemed more dangerous than the disease, and for this reason rapid delivery in eclampsia found but few friends at first. It was only when Bumm, limiting himself to what was most needful, converted the operation into hysterotomia anterior that the position of affairs changed at a stroke. The result seemed to justify commendation, and thus anterior hysterotomy has found friends as a method of treatment for puerperal eclampsia. To-day it is the most widely practised method of rapid delivery. Regardless of any preliminary dilatation of the soft parts, the uterus is at once dilated sufficiently to admit the hand, for turning or application of the forceps to the fœtal head.

Operative treatment by vaginal rapid delivery has no mortality in itself. We may take it as certain that the obstetrician who understands the method and is master of the *technique* will lose no patient by hysterotomy, so long as he has efficient assistance and asepsis is complete. The first requisite is the skill learned from experience. If individual clinics publish all their cases, and therefore report some fatalities, it is explainable by want of dexterity of some of the younger men. They fail to avoid all the errors of *technique*. Amongst these I count incision or tears of the peritoneum or the larger branches of the uterine artery, further, tearing of the wound, and injury to the bladder. All this may be easily avoided.

Anyone who cannot do all this will meet with a misfortune, but the fault will lie not with the operation itself, but with the operator. Naturally it is much to be desired that every obstetrician shall be well enough trained to avoid such injuries, or a more simple method of treatment must be thought out. This objection may be raised against all operations, rapid delivery included, and indeed the art of self criticism is not possessed by every obstetrician. He believes that because brilliant results follow rapid delivery, every obstetrician is at once master of the operation. That is a serious error.

The second requisite is efficient assistance. The experienced obstetrician requires as actual aid only the skilled sister or midwife. The hands that hold the hook forceps and the speculum only need to be covered with a clean glove, and to hold them quietly. These conditions are naturally met by all physicians but not by all midwives. In this way it is explainable why so many different views prevail regarding the technical difficulties of anterior hysterotomy, One will prefer to take his case into the clinic, another will be satisfied to operate in any hovel. I believe that for the majority of cases and in considering the average skilfulness of the assistants removal of the patient to a clinic is to be preferred.

The maintenance of antisepsis goes without saying. When it is really earnestly striven for it will be maintained in spite of difficulties. If all these requisites for success in rapid delivery have been filled, then the individuality comes into play as regards the extraordinary differences in gravity in different cases.

The longer the case has been without treatment, so much the worse will be the prognosis. There are, moreover, cases that from the first can be characterised as difficult. Severe nephritis of which eclampsia is the final stage, intensive destruction of the colouring matter of the blood, a very serious condition of the heart. It is extraordinarily difficult to recognise the bad cases as such immediately. Hæmoglobinuria even is not always fatal.

Therein lies the difficulty of a correct estimation of the value of our methods. Formerly every operation was dangerous. Naturally, with a lessening of the danger of operation, eclampsia is treated more easily. Then it became a near thought to plan out a mode of treatment that was entirely free from danger. Here the use of narcotics came in. G. v. Veit laid the theoretical foundation for their employment. His opinion was that the danger lay only in the attack. Keep off the attacks and the woman was saved. His successes with large doses of morphine were excellent. But he had to make the experience that other clinics that made use of the method found no good in it. One could understand this when large doses of morphine are dangerous in themselves. Quite recently, again, Stroganoff has warmly commended the employment of narcotics. He avoids large doses of morphine; he rather combines it with chloral or makes use of the two in turns as well as cuts short the attacks by chloroform. This method has met with favourers, but there are theoretical objections to it. As it was tried only recently in the Berlin clinics, eight women died out of the first eighteen treated in that way! Naturally, after that one would have to think twice before adopting such a method.

The active methods of treatment were now widely adopted when more recently still W. Zweifel and Lichtenstein added the recommendation of venesection to the narcotic treatment of Stroganoff. As regarded the theoretical basis for this Zweifel rightly pointed out that the blood of an eclamptic patient was poorer in water than that of the normal individual. But the results as recorded by Lichtenstein are very interesting. In treating 80 eclamptic cases, he lost only five. Of the last 60 of these he did not lose a single case. Statistics like these naturally set us thinking. But here even there is something to be considered; only five died out of 80, out of the last 60 not one; therefore out of the first 20, five died, which is a high mortality as regards the first 20.

For this reason I would recommend caution in dealing with statistics. For practical purposes, a comparison must now be made between rapid delivery and the method just considered My material is much smaller than that of the Leipsic clinic. From April 1st, 1904, to February 14th, 1906, I have seen 21 cases of anterior hysterotomy recover in succession. Kapp, amongst others, has reported from Rosthorn's clinic that with the active treatment he lost only one out of 22 cases. We can really do good, then, with rapid delivery. If bad cases come into the clinic, however, we do not do so well. In 1912, I saw 18 cases of eclampsia, of which five died; two of them were in a desperate condition when they were admitted; two further died on the eleventh day after delivery, one of these had remained the whole of the time free from convulsions but unconscious, and the other died from her own severe chronic nephritis in which the eclampsia was only an episode. The fifth patient, who died on the second day, had been seriously ill before this. At the commencement of the year 1906, I was already convinced of the constantly favourable effect of rapid delivery. I almost believed that no death would take place if the patient could have attention in time. Then a fatal case occurred, then a long series of recoveries, then the deaths of the year 1902. In spite of this, however, I consider this rapid delivery to be the correct form of treatment. My conclusion is, however, that in eclampsia there are milder and worse forms. If infection and pneumonia are avoided and the cases are seen early, we can now pull through a series of cases one after another until at last some unlucky ones crop up.

Those cases are the most favourable in which it is possible to deliver the patient immediately after the first convulsion. It seems, therefore, very desirable that in Par. 454 of the new Prussian Handbook of Midwifery for Midwives, an "urgent telephone message" should be substituted for a summons to the physician by letter or messenger. Par. 312, in which this is in general allowed, should be specially borne in mind in cases of eclampsia. Moreover, it is desirable that every examination of an eclamptic woman should be undertaken under a narcotic, but an examination is not generally necessary. When the diagnosis of eclampsia is once clear the patient can be operated on straight away; the condition of the cervix uteri is no longer of any account.

In his recommendation of narcotics, Zweifel lays special stress on any operative delivery being as "sparing" as possible. I have therefore put the question to myself as to whether anterior hysterotomy can be looked on as a "sparing" operation, or whether there may be any fear that pain will remain after the operation that may set up further convulsions. I have operated in a similar way in cases of placenta prævia, in multiparous cases without narcosis, and the patients have never complained of pain. I have performed the same operation in other women under narcosis, and have inquired about any pain as soon as they have come out of the anæsthetic, and have always been assured that they felt no pain. I am not in a position, therefore, to draw any distinction between delivery by anterior hysterotomy with contracted os and delivery by forceps with the os dilated. It is perhaps a proper conclusion that rapid delivery should also include venesection and narcosis, that both methods are good, and that they should be combined. If a case of eclampsia is brought into hospital, the patient should be delivered at once, and if she has lost but little blood during delivery let 500 gm. be taken by venesection. If the patient comes out of the anæsthetic let her have a dose of morphine, and if still restless let her (following the proposal of Stroganoff) have then a following dose of chloralhydrate, and later on another dose of morphine, if necessary, and so on. Or, in the other way we can begin with venesection, and deliver at once if another attack comes on.

I see nothing wrong in combining the two methods of treatment. I shall, as hitherto, deliver at once, and if the fits continue, then try to help further by bleeding and narcotics. That venesection and narcotics are useful in eclampsia is shown by the publications of the Leipsic clinic.

As contrasted with these two methods of treatment, all others so far fall into the background. It is true that certain cases will require special measures. In case of anuria, for instance, which, although rare is occasionally seen in eclampsia, the thought of stripping or incising the kidney will present itself. This procedure will never, however, become routine treatment in eclampsia.

Which of the two methods will be the one mostly chosen will depend on the obstetrician himself. Apparently a good deal of benefit will be found in the combination of the two forms of treatment described. This, however, I would say, is only a preliminary judgment. We have the certain prospect of being able to prepare an antidote for the poison of eclampsia, and we will hope that the discovery of it does not lie too far off. Until then, we have good methods of treatment in rapid delivery, in venesection combined with narcotics, or perhaps in a combination of the whole of the three methods.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Sheffield Neave, B.A.Oxon., M.R.C.P.Lond., Physician to the Queen's Hospital for Children. Subject: "Diagnosis in Respect of Certain Symptoms and Signs in Children."*

ORIGINAL PAPERS.

APEX-TREATMENT FOR PULMONARY CONSUMPTION.

By WILLIAM EWART, M.D.Cantab., F.R.C.P.,

Consulting Physician to St. George's Hospital and to the Belgrave Hospital for Children; formerly Assistant Physician and Pathologist to the Hospital for Consumption, Brompton.

II.

THE APEX IN ÆTIOLOGY AND IN TREATMENT.

A mechanical factor often determines the localisation of the tubercular mischief. In the instance of an injury to a joint, the local disablement of the lymphatic circulation which favours the settlement and the culture of the bacillus would be aggravated by any over use of the damaged joint. The joint has to be rested, in spite of the fact that it had owed its previous protection to its normal activity. Local rest which is essential for the "healing" inflammation, if we may use that term, is less essential for the "infective" inflammation. It is less efficient for the local tuberculosis cure than for the purpose of preventing the dissemination of the bacillus, and of encouraging its self-limiting tendency. Hence *the rest-cure* for local tuberculosis.

In the lung, the most plausible and generally accepted explanation for the *apex liability* which is peculiar to man, is the mechanical explanation based upon his upright station and its anatomical and physiological results at the apex in the shape of less active movement, aëration, and circulation, and of a greater proneness to an imperfect expansion, apt to narrow the circulatory channels which absolute atelectasis completely closes. The phthinoid apex, according to that view, is more predisposed, not owing to greater selective tissue-affinity for the bacillus, but owing to a higher degree of that primary "mechanical" disadvantage. Its special liability is further increased secondarily, at the pretubercular stage, by the general debility which reduces the respiratory activity most definitely at the apex. Hence two prophylactic indications: (1) the mobilisation of the apex, which was contemplated by Freund in his upper costal chondrotomy; and (2) our preventive respiratory hygiene, which aims at expanding the apex by a general expansion of the lung; and also at improving the general and the cardiac energy, for the sake of raising the tissue-resistance in general, and therefore also that of the apex. In their purpose and in their mechanism both methods are mechanical. In both of them the apex-prevention cure is the reverse of the rest-cure; it is an activity-cure. There is, however, this difference between them: Freund's treatment is a direct local apex-treatment, and the other is not.

As regards mere prevention, as Freund's operation is not in vogue, the answer to our first question is in the negative: there is no local apex-treatment at present in use. Prevention still relies entirely upon "general" pulmonary expansion for the purpose of mechanical apex culture and apex improvement; and upon the great "vital" cardio-pulmonary cure of activity as a protection for the apex against local tuberculosis.

In treatment the rest-cure has hitherto obtained, for bacillary considerations, greater attention than the indispensable vital-cure. Nay, in the days of the protracted *liege-kur*, it received an almost exclusive attention. That one-sided cure was too thorough; and at the same time incomplete in the most essential direction. Its sole object was to rest the lesion, which is limited at first to a fraction of one apex. For that object it had to rest not only both lungs and the heart, but the entire body. This implied, not only neglecting the help of the vital cure, but actually depressing, by that systematic universal over-rest, the patient's original vitality. This is a sufficiently clear negative to the question whether any local apex-treatment then existed. No attempt had been made in that direction; and we are not aware that any such attempt has been made since. Under the influence from Nordrach, where Walther stakes most upon the vital cure, Davos ultimately gave up that unphysiological exclusiveness; and it has now adopted the opposite policy, which it is to Paterson's credit to have systematised into the "graduated labour cure." By so much our treatment is far less incomplete than it was, since the indispensable mechanical factor has now been added to it at the finish. But it still remains incomplete at the beginning, when a form of treatment which is effectual even after a prolonged ordeal of disease, ought to be much more effectual then than at any other time. No suggestion has been made to apply that great principle at the start, for the same reason which still delays the earliest administration of tuberculin; simply for fear of the local lesion. Meanwhile the diseased apex does not yet possess any separate treatment of its own. To that extent we are still open to the reproach of inconsistency which attached to the *liege-kur* of old. Our treatment does not differentiate between the diseased tissues and the healthy. Identical measures have to be meted out to both of them alike.

THE HISTORY AND ORIGIN OF THE LEUCOCYTE (WHITE BLOOD CORPUSCLE).

By H. D. McCULLOCH, M.B.Glasg.

Formerly Chief Medical Officer, Hyderabad State Railway Hospitals.

In an interesting contribution to *Science Progress* upon a cytological subject by Dr. Charles Walker, he says (1):—"Except during division (*i.e.*, mitosis) an exchange of substance takes place between nucleus and cytoplasm through the extrusion of the nucleoli. When the cell is in a vegetative condition the nucleoli multiply continually and are extruded from the nucleus. The nuclear membrane is pushed out in front of the migrating nucleolus and closes up behind it as it passes. The staining reaction of the nucleolus changes directly it reaches the cytoplasm." To this he adds the further important statement: "that the differentiation into nucleus and cytoplasm is a definite separation of different functions of the cell into different areas, just as the function of the liver and kidneys are a localisation of certain functions in different areas of the body and different groups of cells. Both are the outcome of more primitive conditions."

It seems to me that the application of these observations to physiological processes in the animal body would be calculated to shed some light upon those processes that are at present little understood. Mainly in connection with leucogenesis and the history of the leucocyte. To me these nucleoli appear to be the precursors of the leucocyte and therefore of the blood cells, so-called. They certainly perform diapedesis by emerging from the nucleus, and they take up stations for chemical elaborative purposes, both endogenous and exogenous.

In other words, they become the cell-organs such, for example, as are termed the plastids, plasmosomes, or bioblasts of Altmann. Some of them may reach the periphery of the cytoplasm, and there under the cell wall fuse together, to form the cell-skin or plasmahaut (2). In attempting to trace the history and origin of the lymphoid and lymphatic systems of glands in man, I have long been under the impression that the cell-plastids must be the precursors of the lymphatic glands, and the cell-skin the precursor of the solitary or lymphoid glands. (*a*) Indeed, on reflection there seems to be the very closest anatomical and physiological analogy. The cell is a "closed corporation," so is the animal body. This fact is emphasised by Adami, in discussing exogenous and endogenous toxins. (3)

The human body is more obviously a closed corporation like the cell, just before the blastomere stage of the impregnated ovum. It continues in this closed state throughout the morula stage, when it begins to lose that appearance, till it seems to have entirely disappeared in the developed embryo and in adult man. Yet, I contend that it is still there—I refer to the "closed corporation," if it be looked for, as Adami has looked into it.

Now these nucleoli described by Dr. Walker cannot be said to be mesodermic in origin, by any kind of argument, for there is no mesoderm in unicellular organisms, and there is no mesoderm up to the morula stage of the human embryo. But there are many cells in the morula, particularly at the vegetative pole, and they are all nucleated cells. Such as are capable at a certain stage, when not dividing, *i.e.*, in the intervals of mitosis, of extruding their nucleoli into the cytoplasm of their respective cells, and these may migrate into the internal media thereby establishing "centres of activity" in definite areas, for the organs that are to be. This would be previous to the establishment of the mesoderm. It certainly is to this stage that, according to Beard, the true origin of the sex cells is to be ascribed (4).

It is conceivable that those migrating nucleoli may be performing similar though more complex functions than in the cytoplasm of the primitive cell. That is to say, that a definite separation of definite functions of the morula into different areas is taking place, in anticipation of the further evolutionary changes that are to follow. Those nucleoli are the precursors of the human leucocytes.

The functions of some are concentrated at that pole, from which the synctial cells are protruded, for the attachment of the embryo to the uterine wall. They are said to achieve this by what has been termed their phagocytic action. (5) The lymphoid and lymphatic analgens are not merely

---

(*a*) The large prickle cells of the cutis constitute the lymphoid glands of the outer surface of the body. McCulloch, *Lancet*, June 28th, 1913.

already there, as the cell-skin and the plastids respectively are in the cell that has been alluded to, but those primitive organ's are symmetrically disposed peripherally, and in a perfect fashion. They begin to lose this symmetry by the first invagination, by which some are displaced, to meet the changing form of the individual. The laying of the "keel-plate" is now synchronous with the development of the mesoderm.

This formation is associated with the development, in air breathing forms, of a *secondary* system of tubular vessels, known as the arteriovenous system. It only came to be needed when a further modification of the non-oxygen carrying and CO_2 converting leucocyte called for modification, and confinement to tubules. So it was that the "migrating" properties of those primitive cells had to be restricted, and another kind of factory established for their production. This had to be so arranged that these more inert cells could be delivered *directly* into those tubules, like coins are at the Mint, where they had to depend for their transportation on other intratubular forces. But the primitive leucocytes and their original factories continued to function outside these tubular channels as of old.

They are known to be avid of oxygen; this is provided for them. They are equally averse to CO_2. They have therefore been free to enter or leave that swiftly circulating fluid, in which some get carried away. It is claimed that leucocytes are as much blood cells as are the red cells. With this view I disagree most emphatically.

To begin with, we see in the large ovoid nucleated red blood cell of the reptilia, an important and edifying stage in the modification I have alluded to. That of the frog, for example, has not been quite deprived of its amœbic properties, nor of its nucleus. I have seen that it is capable of transforming its shape to that of a sphere by constricting and withdrawing its cytoplasm into the linin mesh of the nucleus. It does so in order to pass through the minute capillaries of the lungs, just previous to the gaseous interchanges there.

Moreover, I have successfully demonstrated the fact that no leucocytes whatever gain entrance into the pulmonary capillaries of the frog, before the Physiological Society at its meeting in this city on June 7th last (6). This micro-kinema film demonstration was most conclusive. Indeed, it should be quite clear, that the frog's red cells could not otherwise come into proper function for the purpose that they are undeniably intended. It was then claimed, that if this is so in the case of batrachians, how much more must it be so in mammals, which are exclusively air-breathers, and whose red cells are more completely deprived of amœbic properties and with no nucleus, or one that is so complex that it is not stainable.

The few criticisms that were offered on that occasion rather served to strengthen my views than to weaken them.

I therefore hold that leucocytes are in no sense of the term blood-cells, and that the expression "white blood-cells" is a misleading anomaly, and I invite honest criticism on these views.

As to the further developmental changes and function of the lymphoid and lymphatic systems, I would defer consideration to another article.

SOME ASPECTS OF INTERNAL SECRETION IN DISEASE. (a)

By GEORGE R. MURRAY, M.A., M.D., D.C.L., F.R.C.P.,

Professor of Systematic Medicine in the Victoria University of Manchester; Physician to the Manchester Royal Infirmary.

During the last five and twenty years more and more interest has been taken in the functions and diseases of the ductless glands as their importance has gradually been recognised. Previous to this period, although the structure of these bodies had been described, very little was known as to their functions. Thanks to the efforts of a large number of workers our knowledge of these organs has been largely increased, and the results of their labours have now been brought within the reach of all in the valuable works recently published by Biedl, by Swale Vincent, and by Falta. The great importance of bio-chemistry in pathology is now being more fully recognised, and we are gradually learning that many diseases are due to the failure or perversion of normal chemical processes in which the ductless glands play an important part.

The function of a ductless gland may be affected by disease in different ways. Progressive atrophy gradually diminishes and finally cuts off the supply of its particular secretion, while some special forms of hypertrophy are accompanied by an increase in the amount of secretion which may or may not be normal in composition. We have thus in the case of each gland to consider the results of changes in both the quantity and the quality of its secretion.

The most important ductless glands are the thyroid, parathyroid, pituitary, and suprarenal glands. Other glands, such as the pancreas, the generative glands, and possibly others, supply both an external and an internal secretion. In these glands, however, we find that the two forms of secretion are supplied by different sets of cells, and that one set may fail while the other continues active in function. Thus in the generative glands spermatogenesis may cease while internal secretion persists.

The Thyroid Gland and Thyroidal Insufficiency.

Only 40 years ago Sir William Gull gave us the first account of myxœdema under the name of "a cretinoid state supervening in adult life in women," by which he indicated its relationship to sporadic cretinism already described by Hilton Fagge. Four years later W. M. Ord published five cases, in one of which atrophy of the thyroid gland had been found by Professor W. S. Greenfield, and gave the name of myxœdema to the disease. The experimental work of Sir Victor Horsley, together with the clinical and pathological material collected by the committee, clearly demonstrated that cretinism, myxœdema, and cachexia strumipriva are due to loss of the thyroid gland by disease or removal. The foundation of our present method of treatment had even then been laid by Schiff, who had shown that successful transplantation of a thyroid gland in the dog sufficed to prevent the development of the symptoms which usually followed its removal. This observation was confirmed by von Eiselsberg. In 1890 Sir Victor Horsley drew attention to these important experiments, and suggested that thyroid grafting should be tried as a means of arresting the progress of myxœdema. The adoption of this suggestion was followed by remarkable diminution in the symptoms.

(a) Abstract of the Address in Medicine delivered at the 81st Annual Meeting of the British Medical Association, held at Brighton, July, 1913

It may be mentioned that the first case of myxœdema treated by thyroid extract is still alive and well, a condition of health being maintained by a dose of ten minims of liquid thyroid extract each weekday, or 6½ oz. in the course of the year. Less than a gallon of thyroid extract in all has therefore maintained her in health for 22 years. No variation of the dose has been found necessary.

Thyroid extract naturally finds its fullest opportunity in this supplemental treatment of the various forms of thyroidal insufficiency. Owing to its physiological property of stimulating metabolism and to the iodine it contains, the extract has also been found useful in conditions in which there is no definite evidence that the normal supply of hormones is deficient. The marked emaciation caused by excessive secretion in exophthalmic goitre indicates its employment in obesity, and in some cases good results are obtained, especially if a suitable diet is adopted at the same time. Good results have also been recorded in the treatment of rickets, rheumatoid arthritis, and nocturnal enuresis. The rapid improvement which takes place in the condition of the skin of cases of myxœdema during treatment induced Dr. Byrom Bramwell to employ the extract with conspicuous success in the treatment of psoriasis and other cutaneous diseases. Sir Malcolm Morris has recently dealt fully with the relationships of the internal secretions to dermatology, and has shown how important a part is played by the glandular extracts in the modern treatment of diseases of the skin.

Not only may disease be due to failure of glandular secretion, but it may be the result of the opposite condition of abnormal activity. The secretory activity does not necessarily depend on the size of the gland. Very great enlargement of the thyroid gland may take place in some forms of goitre without any excess of secretion passing into the blood, whereas in Graves's disease a slight increase in size may be accompanied by symptoms of active hypersecretion.

Graves's Disease.

One remarkable feature of the clinical course of Graves's disease is the variability of the symptoms, which in its most marked form is evidenced by the occurrence of crises. We see in some cases general crises of acute thyroidism—that is to say, periods during which almost all the symptoms are aggravated for the time being. The pulse is greatly increased in frequency up to 200 or more per minute; there is great nervous agitation and restlessness, increased tremor, sweating, vomiting, and diarrhœa. These attacks are alarming and dangerous, and in some cases prove fatal within a few days. The general crises are evidently due to a sudden increase in the activity of the thyroid, resulting in the discharge of a larger amount of secretion into the blood stream. Still more interesting is the occurrence of local crises during which, perhaps, a single symptom becomes greatly increased, or one organ or system alone is suddenly thrown into a state of extraordinary activity. Thus some patients are liable to cardiac crises, during which, for no apparent reason, and even when resting in bed, the pulse-rate suddenly increases from 120 to 200 or more per minute. We do not know in what manner the thyroidal hormones produce the rapid rhythm of the heart which is so constant a symptom in Graves's disease. We can produce the tachycardia in a healthy subject by giving large doses of thyroid extract, which, however, does not appear to influence the ventricular rhythm directly.

The considerable number of cases of Graves's disease in which partial or complete recovery takes place shows that the diseased gland is capable of returning to a normal state of activity, but we have still to ascertain precisely under what conditions this favourable result is obtained. General hygienic, medicinal and electrical treatment is followed by gradual improvement and recovery in many cases, but we must require some more rapid means of treatment. In favourable cases some fifteen to twenty weekly doses of the rays have been sufficient to bring about great improvement or practical recovery, but in others only slight improvement has followed a similar course of treatment. The use of a special cytotoxic serum which would induce an atrophy of the thyroid gland has not been satisfactory. Unfortunately a cytotoxic serum is not altogether selective in action, and induces changes in the cells in other organs as well as in the thyroid gland itself. Thyroidectin, though useful in some cases, is not constant in its effects. Rodagen is of doubtful utility, though the fresh milk of a thyroidless goat is useful in some cases, but it may be difficult to obtain one of these goats, and there is the trouble of maintaining the animal during the treatment. The results of surgical treatment in selected cases are satisfactory, but it is to be remembered that there are still considerable risks to be faced, and that recovery does not follow in all cases. The crises call for special treatment as they arise.

The Pituitary Body and Acromegaly.

The pituitary, like the thyroid gland, has a remarkable influence upon metabolism, and the rapid growth and development which normally take place at adolescence are largely due to its activity. Cushing's experiments show that after removal of the hypophysis in adult dogs there are deposition of fat, increased sugar tolerance, lowering of temperature, and abeyance of sexual functions. In puppies there is, in addition, arrest of sexual development and of skeletal growth. In man the effects of pituitary insufficiency are shown in the condition described by Fröhlich and named by Bartels dystrophia adiposogenitalis. There is a remarkable increase in the amount of fat associated with high carbohydrate tolerance, dryness of the skin, impaired nutrition of the hair and nails, and arrested development of the genital organs. It appears, therefore, that hormones supplied by the anterior lobe of the hypophysis activate skeletal growth and sexual development at puberty, control the accumulation of fat, and the nutrition of the skin and its appendages. Sir E. A. Schäfer has shown that the posterior lobe, including the pars intermedia, supplies hormones which regulate the tone and contractility of plain muscular tissue generally and of the heart, and stimulate the activity of the mammary gland and of the kidney. It seems possible that the secretion is polyvalent, and that these various effects are produced by the action of different hormones, as Herring obtained a pituitary hormone from the skate which stimulated the mammary gland without influencing either the circulatory system or the kidney. In addition to these important results, Sir E. A. Schäfer's experiments have placed pituitrin, a very powerful remedy, in our hands, by means of which we can stimulate plain muscular tissue to contract. It is not unreasonable to expect that it may be found possible to separate the hormones which stimulate glandular secretion from those which act upon the unstriped muscle and so further increase their range of usefulness in the treatment of disease.

Not only may disease be due to lack of pituitary hormones, but a remarkable change in the body arises when the supply of these hormones is superabundant. When this occurs in the adult the hypersecretion leads to the characteristic changes of acromegaly. In the active stage of acromegaly we can expect no benefit from the use of pituitary extract, though thyroid extract has proved to be of service in some cases. The means at our disposal at present for diminishing the over-activity of the hypophysis are the use of X-rays and surgical measures for the relief of local pressure symptoms by decompression or the removal of some of the enlarged anterior lobe of the gland, so as to diminish the supply of its secretion. Owing to the deeply-seated position of the hypophysis the actual dose of X-rays which can reach it must be small. The chief benefit obtained by surgical measures has been the relief of symptoms such as headache and improvement of vision resulting from the diminution of local pressure thus brought about, and is comparable to that obtained by the removal of a portion of a goitre which is compressing the trachea.

The Suprarenal and Generative Glands.

Failure of the suprarenal glands is the immediate cause of Addison's disease, in which there are increased pigmentation of the skin, vomiting, and great prostration, with lowered blood pressure. Though the suprarenal insufficiency is most commonly due to tuberculosis of the glands, Rolleston has shown that other destructive lesions, such as simple atrophy, produce the same result. We know little of the functions of the suprarenal cortex, but it seems not improbable that while the low blood pressure and prostration in Addison's disease are due to loss of adrenalin from destruction of the medulla, the bronzing of the skin is due to loss of the cortex. In adrenalin we possess a remedy the value of which is fully recognised as a hæmostatic and in the treatment of asthma and other conditions. Something more than this, however, is lacking in Addison's disease, as, unfortunately, neither adrenalin nor extracts of the whole suprarenal gland are able to replace the diseased gland in this malady.

It has long been known that the generative glands exercise a dual function, and that their removal not only induces sterility but other remarkable effects as well. Castration in early life prevents the development of secondary sexual characters; thus the antlers do not develop in stags which have been castrated when quite young. Spermatogenesis and internal secretion, the two functions of the testicle, can be separated experimentally, as the internal secretion is in all probability furnished separately by the interstitial cells of Leydig. While ligature of the spermatic cord produces the same result as castration, ligature of the vasa deferentia entails sterility alone. It has been shown by Shattock and Seligmann that the latter operation in sheep does not prevent the full development of secondary male characters, as the vascular supply remains intact and the normal amount of testicular hormone reaches the general circulation. Similar effects are produced by X-rays, which induce sterility without arresting internal secretion, as they spare the cells of Leydig.

There is a close relationship between the functions of the generative gland in both sexes and other ductless glands. The absence of sexual development at puberty in cretins and in cases of pituitary insufficiency clearly indicates that both the thyroid and pituitary glands normally exert a powerful influence on the development of both testicle and ovary. This relationship is still further illustrated by the remarkable development of these glands which takes place under the influence of thyroid extract in an adult cretin, who has long passed the normal age of puberty.

The results of loss of the secretion of the ovaries are seen after their removal by operation and at the normal climacterium. The symptoms which then occur are variable in character, but hot flushes, irregular perspiration, morbid fears of organic disease, and various subjective sensations are common. It is rather remarkable that so little attention is devoted to their consideration in our medical textbooks, and that their true nature is apt to be overlooked.

This brief survey of some of the results which follow any abnormal ebb and flow of the internal secretions in disease indicates how important are the functions of the ductless glands.

THE MEDICAL HISTORY OF BRIGHTON. (*a*)

By W. AINSLIE HOLLIS, M.A., M.D., F.R.C.P.,
Consulting Physician to the Royal Sussex County Hospital, Brighton.

After referring to previous Presidential addresses of an historical and archæological character delivered before the Association in 1896 and 1912, Dr. Hollis proceeded as follows:—

In the local museum two relics of the early bronze age found at Lancing may have been used in surgery. One (catalogued in a metropolitan museum which has several specimens as "spoon to extract unguents from narrow-necked bottles") is very like a guider or director, and the other a scraper, figured in the old English and Dutch editions of Ambroise Paré's work on surgery. They may have been used for operative purposes.

After the Norman Conquest "a convent of

(*a*) Abstract of Presidential Address delivered at the 81st Annual Meeting of the British Medical Association, held at Brighton, July, 1913.

mendicant friars more burthensome than ten endowed ones," was founded at Brighton on the land now occupied by the market and Town Hall. A chantry or free chapel was attached to the *convent*, which was probably only a small building. This offshoot of the Lewesian monastery, amongst other duties, saw to the due collection of the annual rent or *gablum* of the manor of Bristelmestune from the fisherfolk living there. So far as I can ascertain, surgery at this period of the world's history consisted mainly of "blooding" the patient and it is possible that the friars dwelling in the Prior's Lodge at Brighton, by resorting to this simple operation, did so far help the poor overtaxed fisherfolk when sick. In so doing the holy friars would only be following the footsteps of the νοσοκόμοι (infirmarers), of the Stadium monastery at Constantinople, and of Master Rahere and his brethren at St. Bartholomew's, London. At that time "blooding" was a fine art, and experts withdrew blood from different parts of the head, neck, body, and limbs, to combat the various symptoms for which relief was asked by the patient.

Nevertheless, surgery was in a sorry plight during these centuries of monkish rule; whilst, during the age of flint implements, "ancient skulls with clear signs on them of extensive operations, and limb bones with well-healed fractures show that there were daring and successful surgeons among the Europeans of the neolithic age." On the other hand amongst the many hundreds of skeletons found within the precincts of the Priory grounds at Lewes, Dr. Mantell says, "Several examples of unskilful surgery 'of the good old times' were pointed out to me by my friend, Mr. Warren Lee. An arm bone, which had been broken asunder transversely, and had become firmly united, was 2 ins. shorter than natural, from the fractured ends projecting over each other. A thigh bone that had been dislocated upwards had never been replaced, but was ankylosed to the pelvis and its socket obliterated; the holy brother to whom it belonged must, therefore, have suffered severely, and have halted very sadly in his walk for the remainder of his days. Of bony tumours and scrofulous caries of the bones there were several instances." Such, then, was the condition of surgery in the area of this Division of the British Medical Association during the Middle Ages.

The Belief in the Royal Touch.

After the disastrous defeat at Worcester and just before his departure for France, Charles II. slept for one night at an inn in Brighton. According to Richard Wiseman, his Sergeant-Surgeon, this monarch possessed in an eminent degree "the admirable faculty of curing the struma" by the touch. To quote Wiseman's own words, "I myself have been a frequent eye witness of many hundreds of cures performed by his Majesty's Touch alone; without any assistance of chirurgery; and those many of them, such as had tired out the endeavours of able chirurgeons before they came thither."

It is difficult to understand how such an eminent surgeon could uphold the current superstitions concerning the Royal Touch in the way he has here done. Wiseman, I need hardly remind you, introduced into England the tying of arteries, and he advocated the excision of diseased glands whenever possible, "taking care meanwhile not to divide the cystis, so that matter flow out."

The "Discovery" of Brighton.

About the year 1750 Dr. Richard Russel, Physician to St. Thomas's Hospital, published in Latin his *Dissertatio de Tabe Glandulari et de usu Aquae Marinae in Morbis Glandularum.* A year or so afterwards—the exact date is doubtful—he "discovered Brighton." He resided there annually during the season until his death in 1759. His essay on sea water is somewhat discursive. The cases selected for publication as among those benefited by the external or the internal administration of sea water included patients suffering from struma, constipation, renal calculus, "scirrhus," and other diseases. His contemporary, Dr. Speed, in a *Commentary on Sea Water*, wrote: "I think we ought to attribute the Alleviation to the prudent Use of other select Medicines which this Author [Dr. Russel] employed rather than to the drinking of Sea Water." Be this as it may, Dr. Russel, who was very popular, especially among the ladies, undoubtedly attracted many fashionable folk to the town by his advocacy of sea bathing and sea water. His widowed daughter, Hannah, married William Pepys, a collateral descendant of Samuel, the diarist. About ten years after the death of Russel, Dr. Awsiter tried to revive the flagging interest of the public in the relief of disorders by the use of sea water as a remedy. In a pamphlet (published in 1768) he strongly advocates sea-bathing. "We should use exercise after bathing, and those who cannot should have their limbs well rubbed, and their bodies warmly but not hotly cloathed to renew a proper degree of perspiration." The baths lately erected (1759), after the plans of Mr. Golden, architect, near the Steyne, were also highly commended by Awsiter. "On one side of a spacious vestibule are six cold baths, on the other side are hot baths, sweating baths, and showering baths; the baths are supplied from the sea by means of an engine."

Rabies and Hydrophobia.

Awsiter recommended the use of sea-salt as a remedy for hydrophobia, and mentioned with approval Russel's suggestion that in such case the salt should be dissolved in urine, "whereby the power of the salt in destroying the acrimony and poisonous quality of sores and wounds is invigorated."

Rabies was seemingly endemic in this part of England during the latter half of the eighteenth century. The disease was, according to the papers, by no means confined to dogs. Other domestic animals were occasionally affected. Both kine and swine often went mad, when bitten by a mad dog.

As regards human beings, although from time to time both children and adults were stated to have been bitten, there are few recorded cases of hydrophobia in the columns of the local journal.

Several outbreaks of small-pox occurred in this part of Sussex during the latter half of the eighteenth century. Inoculation was strongly advocated as a protection against the disease by the local doctors, and the operation appears to have been generally accepted by the people as a necessary, if regrettable, evil. At a vestry meeting at Brighton in 1780, again in 1786, and in January, 1794, at Rye, Eastbourne, and at Brighton (after some opposition) general inoculations were decided on. At Brighton, with a population of 5,669, 2,113 were inoculated, "out of whom only 50 died"!

Recent Times.

During the first quarter of the nineteenth century dispensaries, sea-bathing infirmaries, and hospitals were founded and opened for the relief of the sick poor in Brighton and other Sussex towns. Special institutions were also established for the treatment of special disorders, until the Sussex yokel had no need to envy the tillers of old Egypt's fertile soil in that regard.

In 1851 (August 14th) the Provincial Medical and Surgical Association held its annual meeting at Brighton under the Presidency of Dr. William King, late Fellow of Peterhouse, Cambridge, and Senior Physician to the Sussex County Hospital. His address, which was somewhat discursive, treated, amongst other matters, of the therapeutic value of artificial mineral waters prepared by a new recipe which he disclosed.

The Provincial Medical and Surgical Association on October 17th, 1874, was transformed into the British Medical Association in a memorandum of association signed by fourteen original members.

Thomas Addison, the discoverer of the disease of the suprarenal capsules which bears his name, retired here in broken health after an active life in the metropolis, and died at Brighton in 1860.

William Withers Moore, D.C.L., M.D., F.R.C.P., who was President of this Association on the occasion of its last visit to Brighton in 1886, was born at Doncaster in 1823, and was the third son of John Moore, surgeon. Moore was educated at Doncaster and at University College, London. He took the M.D.Edin. He practised both in Doncaster and in Brighton. At the time of his death, which took place from angina in 1894, he was consulting physician to the Sussex County Hospital. Dr. Moore selected as the subject of his Presidential address, "The higher education of women." His opinion may be gathered from the following extract:—

"I think that it is *not* for the good of the human race . . . that women should be freed from the restraints which law and custom have imposed upon them, and should receive an education intended to prepare them for the exercise of brain power in competition with men."

I should this evening be sorry to endorse these words as the considered policy of the President of this Association. As regards the great sex question, public opinion has changed during the last seven and twenty years; and women look upon the question from a different view-point to that they then held. The British Medical Association has always welcomed lady diplomates in medicine as honoured members of its body, and it has extended to all its members equal privileges, regardless of sex. I trust that this truly democratic spirit will always pervade its policy.

OPERATING THEATRES,

KING EDWARD MEMORIAL HOSPITAL, EALING.

Strangulated and Gangrenous Meckel's Diverticulum.—Mr. Carless operated on a girl, æt. 23, who had been admitted in an almost pulseless condition suffering from abdominal pain of three days' duration together with fæcal vomiting. The story was that three days previously she was awakened by severe abdominal pain during the night; it was probable she had indulged in an indigestible supper the previous evening. A doctor was sent for next morning as the pain persisted. A dose of castor oil was administered. The symptoms progressed during the next day or two, and she was then admitted to the hospital in a badly collapsed condition. A small dose of morphia was promptly given to relieve the pain, and an intravenous saline infusion was administered whilst the surgeon was coming from town. The result of this was very satisfactory, the patient's condition improving immensely. On examination, the abdomen was found to be distended, more on the right side than on the left, but it was not typically hard and resistant; in particular the epigastrium was soft, as also the suprapubic region. On vaginal examination, it was thought there was some fulness in Douglas's pouch. The patient's colour was good and her menses had been regular. This latter fact eliminated the question of ruptured tubal gestation; the absence of epigastric rigidity and of any previous history of indigestion excluded a diagnosis of perforated gastric ulcer. The condition of the right iliac fossa and the absence of pyrexia made one doubt that the origin of the trouble was in the appendix, and a diagnosis was suggested of internal strangulation under a band. The fact that the pain started during sleep is a very common history in such a condition, and the persistence of vomiting, finally becoming fæcal, without any characteristic rigidity or tenderness in the right iliac region, supported such an idea.

The patient was removed to the operating theatre, and after the necessary cleansing the abdomen was opened in the middle line below the umbilicus, the incision subsequently being extended upwards. As soon as the peritoneal cavity was opened a quantity of blood-stained serous fluid escaped, and the remark was made that this probably confirmed the diagnosis. Several coils of distended small intestine were allowed to escape, and it was then possible to see a tense, black swelling about the size of a small hen's egg, placed deeply in the right iliac fossa. It was held in place, and could not be drawn to the surface, but its relation to the surrounding parts was difficult to determine owing to intestinal distension. Relief of this was essential, and therefore a coil was tapped with a medium-sized trochar and cannula, and a large quantity of blood-stained fæcal material and gas was allowed to escape. This opening in the intestine was sutured, and it was now possible to determine that the black mass was a portion of the small intestine strangled by a band formed by an adhesion between the extremity of the Fallopian tube and the cæcum. A small Kobelt cyst was present at the tubal end of the adhesion. An aneurysm needle was passed under the adhesion, which was then divided at each end. This set free the gangrenous mass, which was drawn up out of the wound and found to consist of Meckel's diverticulum, together with a small portion of intestine on either side of it. Relief of the constriction made no difference to the condition of the gangrenous mass, which was offensive and surrounded by inflamed coils of intestine, including the cæcum and appendix.

By this time the patient's condition had again become exceedingly bad, and it was impossible to undertake an entero-anastomosis. Consequently the dead portion of the gut was cut away, and a large rubber tube stitched into the upper end and a Paul's tube into the lower. The coil of gut was left out and the abdominal wall closed loosely around it. Saline venous infusion was again had recourse to, a few drops of adrenalin being added to the salt solution. The patient recovered consciousness and lived for about 36 hours, but the bowel was obviously paralysed as the result of the general peritonitis, and there was no further discharge from either tube.

It was unfortunate that the patient came under observation so late, as her condition was one easily amenable to surgical treatment if taken early enough. Meckel's diverticulum is by no means an uncommon congenital abnormality and gives rise to many pathological conditions: it may constitute a band which determines obstruction; it may become adherent to some other structure and by traction on the latter cause an acute kink; it may become a place of lodgment for an intestinal or biliary calculus and give rise to a condition analogous to acute appendicitis; it may remain as a diverticulum and cause severe colic. All of these conditions have passed under Mr. Carless's notice, but this was the first occasion, so far as he remembered, in which the diverticulum itself became strangled under an adhesion. Acute strangulation of the intestine under such an adhesion is not very uncommon, and the occurrence of acute abdominal symptoms in a young person, associated with persistent vomiting becoming fæcal, together with more or less marked constipation, in the absence of typical symptoms of perforated gastric ulcer, or of acute appendicitis, or of anæmia caused by a ruptured tubal gestation, or of an ovarian cyst with twisted pedicle, should at once suggest to the surgeon the probability of a mishap of this character. It need hardly be mentioned that a most careful examination of all the hernial apertures, normal and abnormal, should be made before internal strangulation is diagnosed, for a small strangulated femoral hernia is very easily overlooked.

SPECIAL REPORTS.

THE EIGHTY-FIRST ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION, HELD AT BRIGHTON, 1913.

[By Our Special Representative.]

SECOND ARTICLE.

Favoured by genial, if not sultry, weather, the general impression at the conclusion of this, the 81st annual meeting, is that it has been one of the most successful of recent years. The work in the sections has been of a high scientific order, the discussions have been well sustained, while the arrangements made for the entertainment of the members both by the town municipal authorities of Brighton and Hove, and also by the local medical profession, have been characterised by a lavish display of hospitality. The citizens of Brighton also added their welcome, so that during the busy days of the congress the most cordial relations existed between the town folk and their visitors. The magic passport of the card of membership provided free admission to the principal clubs and several local places of interest. The Hon. Local Secretary, Dr. L. A. Parry, is to be greatly congratulated upon the phenomenal success of this gathering, which it was feared at one time might be jeopardised by the proximity of the International Congress of Medicine. These fears, happily, have not been realised.

On the Tuesday afternoon at the annual general meeting, the President-elect, Sir Alexander Ogston, K.C.V.O., Consulting Surgeon to the Aberdeen Royal Infirmary, was introduced, and it was formally announced that the meeting would take place in Aberdeen in 1914.

One of the principal events in connection with the annual meting has been the presentation of the Gold Medal of Merit awarded by the Association for conspicuous services rendered to it to Dr. J. A. MacDonald, of Taunton, the Chairman of Council.

Religious Services.

According to long-established custom, the annual Church Service was held in the Parish Church of St. Peter. A large number of members, duly attired in academic costume, marched through the Municipal Gardens, headed by the Mayors and Corporations of Brighton and Hove, who attended in state, to the seats reserved for them. The lesson was read by Mr. T. Jenner Verrall, M.R.C.S., and the sermon was preached by Canon John Wakeford, M.A., B.D., Precentor of Lincoln Cathedral, who delivered a striking discourse on St. John, xix. 20: "It was written in Hebrew, Greek and Latin." In modern times there was not only that danger of specialisation in science, but of the over-emphasis of the physical in the medical profession. Health meant wholeness, completeness, and was not a local condition, but the harmony of the whole being, with the moral and the mental effective as well as the physical and the material. Our great need was to realise the unity of human nature, the harmony between body and soul, so that we dealt with both and ministered to the whole, not one division or section, of human nature. It was neglect of this truth that enabled their critics to cavil; his appeal to his hearers was to close their ranks and in the frank confidence that reigned between doctors and clergy let them insist upon it that they should see human life whole, the one helping the other.

The collection was divided equally between the Parish Church of Brighton, Epsom College, and the Royal Medical Benevolent College.

Earlier in the day there was a Roman Catholic Service at the Church of St. John the Baptist, Bristol Road, conducted by the Right Rev. Mgr. Canon Johnston, of Brighton, who preached from Acts xvii., 28. He asked his audience to realise more and more the responsibility of their high calling, and he said that it was a source of strength to him and his colleagues to see by their side, in the hospitals and homes of the sick, the devoted love and skill of the doctor. After the service of Mass, Mgr. Johnston kindly showed those present the objects of interest in the church, which included among them the tomb of Mrs. Fitzherbert, the wife of George IV.

The President's Address.

A large and distinguished audience assembled in the Dome on Tuesday evening to hear the President's address. The Mayor of Brighton (Alderman Thomas Stanford, J.P.) opened the proceedings by welcoming the members and delegates to Brighton. A replica of the Presidential badge was then presented to Dr. Hollis on behalf of the local division, and the badge was placed around the neck of Mrs. Hollis amidst tumultuous applause. Mr. T. Jenner Verrall, the Chairman of the representative meeting, on behalf of the Council, presented the Gold Medal of the Association mentioned above to Dr. J. A. MacDonald, LL.D. The Stewart prize of £50, instituted by the late Dr. Alexander Patrick Stewart, in recognition of work done in research in epidemic diseases, was awarded by the President to Mr. William Leonard Braddon, F.R.C.S., for his work in connection with beri-beri.

In choosing for his subject "The Medical History of Brighton and its Neighbourhood," Dr. Hollis delivered an address full of antiquarian and medical interest. A full abstract of the address will be found on p. 118.

The Address in Medicine.

At the Royal Pavilion a large company assembled in the Music Room to hear the Address in Medicine by Professor George R. Murray, M.A., M.D., F.R.C.P., Physician to the Manchester Royal Infirmary, who chose for his subject that of the internal secretion of the ductless glands. In spite of years of investigation by many experts the speaker confessed that the mode of action of the internal secretions was still obscure, though knowledge of their effects was gradually expanding. Generally speaking, ductless glands acted on other tissues at a distance by means of "hormones," which were conveyed by the blood stream to the cells for which they were destined. A full abstract of the address appears elsewhere in our columns (p. 116.)

The Address in Surgery.

This was delivered on the Thursday by Sir Berkeley Moynihan, M.S., F.R.C.S., Professor of Clinical Surgery in the University of Leeds, who chose for his subject "The Gifts of Surgery to Medicine." The two branches of therapeutics, medicine and surgery, were by no means antagonistic; rather they were one and indivisible. Recent years had, however, shown the power of surgical research to enlarge the scope and enrich the knowledge of many of the problems of internal medicine. By a study of what he ventured to call the "pathology of the living," a very profound change had by degrees crept over our knowledge of almost every form of chronic abdominal disorder. In surgery, as in other arts, simplicity was the supreme virtue. Sir Berkeley Moynihan referred to the hypothesis that intestinal stasis might be responsible for many other diseases which attack, not only the abdominal viscera, but also parts remote therefrom. Medicine in its quest for knowledge might rightly levy a tribute from every other science with which it comes into contact. Clinical research, when sedulously conducted and illuminated by the disclosures made upon the operating table, afforded the most accurate of all methods of investigation into the diseases by which man was attacked. We hope to publish a full abstract of this interesting address in our next issue.

The Annual Dinner.

On the Thursday night the annual dinner of the Association was held in the Town Hall, Hove. The President, Dr. Hollis, occupied the chair, and he was supported by the Mayor of Hove (Alderman Barnett Marks, J.P.), Captain G. C. Tryon, M.P., the Mayor of Brighton (Alderman C. Thomas-Stanford, J.P.), the Hon. John Gordon, M.P., the Dean of Chichester, the Vicar of Brighton, Professor Pfeiffer, Professor Grober, Sir William Leishman, Sir Jas. Barr (ex-President), Mr. T. Jenner Verrall (Chairman, Representative Meetings), Rev. Canon Wakeford, the Mayor of Lewes (Councillor Hugh Stott), Alderman Gervis, M.B., J.P. (Chairman of Brighton Division), Dr. J. A. Macdonald (Chairman of Council), Dr. G. R. Murray, Mr. Rayner (Treasurer), Professor Foerster, Dr. Dawson Williams, Dr. Robert Jones, Rev. J. B. Figgis, Dr. G. Morgan, Mr. E. B. Turner (Deputy Chairman, Representative Meetings), Mr. Thelwall Thomas, Sir Berkeley Moynihan, Rev. Mgr. Canon Johnston, Rev. W. R. Dawson, Dr. S. B. Figgis, Dr. L. A. Parry (local Hon. Secretary), Mr. Guy Elliston (Financial Secretary), Dr. A. Cox (Medical Secretary), Dr. Ryle, J.P., and Dr. Neal (Medical Secretary). The vice-chairs were occupied by Drs. Whittington, Benham, Broadbent, Hobhouse, Fothergill, Ryding Marsh and Taylor, and about 300 sat down to the excellent repast served by Messrs. Booth and Sons.

After the loyal toasts had been honoured, Dr. J. A. MacDonald proposed "The Municipalities of Brighton and Hove." Speaking on behalf of the Association, he expressed the highest appreciation of the way in which the members had been received in Brighton and Hove, remarking that on no occasion had they had a better welcome. (Applause.)

The Mayors of the two boroughs having replied, the Vicar of Brighton gave "The British Medical Association." Begun with 40 members, the B.M.A. now numbered some 26,000, and included all the leading and most distinguished men in the profession. It carried its branches into all the distant parts of the world, wherever, in fact, the British flag flew; and the fact that it voted annually a very large sum of money for scientific research and betterment of their own profession and of men who were very often working under great difficulties was the best testimony to the value of their work and the extensive influence it exerted throughout the community at large.

Perhaps they had at this Conference found it difficult to carry out the serious work of the Association in addition to attending the many social functions given in their honour; but his own experience, after attending one of their scientific sections, had been that he came away with very grave doubts as to whether he was fit to live (laughter), while the enlightenment he gained on another subject was that he ought to have spent the greater part of his existence in prison. (Laughter.)

In returning thanks, Mr. T. Jenner Verrall said that the Representative body was, by the constitution, a centre of the energies of the Association, and he happened to be for the time its presiding genius—of sorts (laughter and applause). Their good wishes were by no means inopportune, for on account of certain recent public events, joints in their armour had been somewhat strained, not seriously or permanently, but for the time being tried. It was said in a celebrated letter that the writer understood that among those who were to receive it there were divisions, and he went on to say that he partly believed it. Had the letter been written to them he need have had no demur as to the truth of the report, but he (Mr. Verrall) would ask them: Were those divisions incurable? (Cries of "No"). He said "Certainly not." If he had any doubt about that he should have no pleasure in continuing the work of the Association. It had been intimated to him that by continuing another year in office he might help in the healing of any temporary feeling of soreness—(applause)—and it was for that reason that he had accepted this further term of office. His fears might be wrong as to their estimate of his personal influence ("No, no"), and he might miscalculate his physical capacity and energy, but as things were he would rather fail than not try. Any changes in the constitution of the Association should be undertaken gradually and quietly. If their constitution was to be turned into the melting-pot, out of the fine material that would be available for use it would be as possible to construct a colossal statue of Peace as a 4.7 gun. Touching a personal note in conclusion, Mr. Verrall said that as a Sussex man, Brighton born, he could hardly tell them how much it meant to him to come back there in the position he held on this occasion (applause).

The toast of "Our Guests" was proposed by Alderman Gervis, M.B., J.P., who coupled with it the names of Professor W. Pfeiffer, of Essen, Germany, and of the Rev. W. R. Dawson, as one who had raised Brighton College to a prominent place in the public schools of this country (applause).

These having suitably replied, the health of the President was proposed by Sir James Barr in eulogistic terms, to which Dr. Hollis responded.

The Firework Display.

A unique feature of the gathering was the magnificent display of fireworks on the Thursday night, immediately following the annual dinner. Thousands of people had assembled upon the promenade to witness a sight which proved to be a veritable triumph of pyrotechnic art. Among the many fascinating figure displays was a portrait of Dr. Hollis. The display concluded with complete success with a fire portrait of the King, from a recently-taken photograph, and this was accompanied by a royal salute. Early in the evening there was worded across the lawns in brilliant lines, "Hearty Good Wishes to All"; at the close there blazed out in dazzling radiance, "Goodnight." Mr. A. O. Gardener personally supervised the arrangements for Messrs. C. T. Brock and Co. ("Crystal Palace" Fireworks, Ltd.), and to him the Entertainment Committee of the British Medical Association, which conceived the idea, and the public generally who were provided with one of the greatest attractions in the history of Brighton and Hove, are grateful.

Various Meetings.

The summer meeting of the Irish Medical Schools and Graduates' Association took the form of a luncheon held at the Hotel Metropole on the Wednesday. Dr. W. Douglas, the President, was in the chair, and a large gathering of members and guests had assembled. The toast of the "British Medical Association" was felicitously proposed by Dr. H. Macnaughton Jones, who coupled with it the name of Dr. J. A. MacDonald.

The toast was received with cheers, and in replying, Dr. MacDonald said that the Association in the future was going to do what it did in the past—its very best in the interests of the members at large (Hear, hear). The past year had been a troublous one, and the Association had been very much blamed in many quarters for not having done better. In that connection he said the fault did not lie with the Association, but with the members of the Association themselves (Hear, hear). They did remarkably well, though, in his opinion. They were opposed to the strongest power in the world, the British Government, and actually had it on its knees for ten days last December. Then doctors through misrepresentation gave way, got scared by an unscrupulous campaign in the Press and by other influences that were brought to bear. He did not altogether blame the doctors; rather he was sorry, because they made an error of judgment and would have done much better had they remained steadfast. Still, if they would only look at the Bill that was introduced and the Act at the present time they would find the British Medical Association had done very well (applause).

The toast of "The Irish Medical Schools and Graduates' Association" was proposed by Dr. G. Pernet, and the President, Dr. Douglas, responding, mentioned that he had the honour of inaugurating these luncheons some years ago, and they enabled them to bring men together who could not conveniently go up to London to their larger meetings. The success the Graduates' Association had experienced in the past would, he believed, be enlarged in the future (applause).

"Our Guests" was submitted by the Chairman, which was responded to by Mgnr. Johnston, of Brighton.

The Temperance Breakfast.

On the Thursday morning, at 8.15, a large gathering assembled in the banqueting room of the Royal Pavilion for the 43rd annual breakfast arranged by the National Temperance League. Dr. W. Ainslie Hollis presided, and an address was delivered by Mrs. Mary Scharlieb, M.D., M.S., who dwelt on the responsibilities of the medical profession with regard to temperance in child-bearing women. The evil effects of alcohol upon them fell especially upon their offspring, for immature tissues were vulnerable and specially susceptible to the action of alcohol. Dr. Arthur Newsholme, formerly M.O.H. of Brighton, proposed, and Dr. R. Murray Leslie seconded, a hearty vote of thanks to the speaker and also to the President.

Exhibitions.

Horlick's Malted Milk Company made a good show with their well-known products. There is no need to remind medical men that the root principle of their process is the presentation of milk in a form that does not curdle in dense masses. If treated with rennet or lemon juice it is precipitated as a fine, soft, flocculent, and hence readily digestible deposit. One excellent new product is the Malted Milk Lunch Tablet, especially intended for business and professional men, lawyers, clergymen, lecturers, vocalists, travellers, golfers, sportsmen, athletes, and cyclists. The tablet is most palatable, and can be carried about in a small bottle in the vest coat packet. We venture to prophesy a great future for these tablets.

The Saccharin Corporation had a handsome stall opposite the main entrance. One of their new products is a valerian preparation, Trivalin (Overlach), a nerve tonic and substitute for morphia. It contains four active principles—valerianic acid, morphia, caffeine, and cocaine. A special advantage claimed for Trivalin is that it does not cause the sickness and persistent vomiting apt to follow the use of morphia. It is given in doses of 1 c.c. once to thrice daily, and is conveniently dispensed in chocolate-covered pilules, which, by the way, are free from the slightest scent of valerian. The Dry Diamalt of the same corporation is now well known as a crystalline malt extract of high digestive and nutritive value. It is made under careful supervision (always essential to this kind of preparation) at Sawbridgworth, in Hertfordshire. It is worthy of note that the product is not touched by hand either in manufacture or in packing, and that it requires no preservative. Medical men in want of anything of the kind will do well to apply to the Saccharin Corporation, 10, Arthur Street, London, E.C., for samples.

Charles Hearson and Co. had an efficient electric centrifuge, carrying four tubes, and attaining 3,200 to 3,500 revolutions per minute, at a cost of £7 to £10, according to size and fittings. The same firm showed their well-known bacteriological incubators, paraffin ovens, and other laboratory apparatus.

CENTRAL MIDWIVES BOARD.

The Board met on July 24th, Sir Francis Champneys presiding. The correspondence dealt with by the Standing Committee included a letter from the Local Government Board transmitting a copy of a letter addressed to the president by Messrs. R. Turner and Son, solicitors, Manchester, on behalf of Mrs. Mary Underwood, Llandudno, complaining of the conduct of a certain midwife. The Board's reply was to the effect that they had heard nothing from the County Council of Carnarvon.

Abnormal Cases Requiring Medical Aid.

To a letter from the Medical Officer of Health for the City of Manchester asking the Board to regard all breech presentations as abnormal cases requiring medical aid, it was agreed to reply that the matter had received careful consideration at each revision of the rules, and that the present rule seemed the most satisfactory, but that the M.O.H.'s letter should be filed for consideration at the next revision of the rules. Letters from a certified midwife, approved by the Board for the purpose of training pupils, complaining of the conduct of another midwife who had been trained by her, resulted in the Board's decision that the complainant herself should be struck off the list of approved midwives, and the matter be referred for further consideration to the Penal Cases Committee.

The previous day the Board held a penal session, when eight out of eleven midwives cited to appear before them were struck off the roll.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, July 26th, 1913.

Subcutaneous Injections of Oxygen Gas.

We have already referred to the utility of subcutaneous injections of oxygen gas in certain affections where the system is very depressed, as in grave pneumonia, pernicious anæmia, consumption, and in all chronic maladies where active regeneration of the blood is indicated. Asphyxia is one of those accidents where this method renders immediate service.

Dr. Bayeux, who has employed these injections in hundreds of cases, has invented an apparatus as convenient as it is simple. It is composed of a polydetensor enclosed in a small box and recipient containing 15 litres of gas that can be carried in the pocket—that is to say, a sufficient quantity for 20 injections.

In cases of asphyxia as many litres as possible should be injected, but in chronic affections certain doses should not be exceeded, and above all the gas should not be injected too rapidly, otherwise the patient would suffer more or less from tension. The rules given by the author are : (*a*) Quantity of gas not to exceed half a litre for the adult, 300 cubic centimetres for the adolescent, 200 for children, and 100 for infants. (*b*) Rapidity of injection not to exceed 4 litres per hour, frequently 3 litres, or ten minutes for 500 c.c. (*c*) Renewal of injection every third day. (*d*) Points of election, the areolar tissue of the flank or the external third of the thigh.

The usual antiseptic precautions being observed, subcutaneous injections of oxygen gas are absolutely without danger; thousands of injections have already been practised without the slightest accident. The method is becoming quickly popular.

Treatment of Tetanus.

The treatment of tetanus is preventive and curative. The preventive treatment, says Dr. Sicard in the *Monde Médical*, consists in sterilising the wound soiled by earth or manure and destroying, if possible, the microbe of Nicolaier by careful disinfection (oxygen water, tincture of iodine), and neutralising the tetanic toxine by preventive injection of antitetanic serum. This latter, however, cannot be relied upon with absolute certainty, as its effects last only eight days, yet it will be always the duty of the surgeon to give the patient the benefit, if any, of the treatment. According to Descamps the injection should be given as soon as possible after the accident and the region injected, arm, flank, thigh, carefully disinfected. Large doses should be given (10 to 30 c.c.) and renewed the following day and two or three days subsequently. In grave traumatisms or prolonged suppuration the serum should be repeated every week until the wound is healed.

The curative treatment embraces a series of therapeutic measures. First, the wound must receive attention, being disinfected, curetted, excised when possible. Against nervous excitability, large loses of chloral associated with bromide of potassium (two or three drachms a day) are prescribed. Bacelli recommends subcutaneous injection of a 2 per cent. solution of phenic acid. More recently sulphate of magnesia has been employed with some encouraging results. Three cubic centimetres of a 25 per cent. solution are injected into the medullary canal, as for lumbar puncture.

In a case of confirmed tetanus, much cannot be expected from serotherapy. However, it should always be tried, as certain authors have reported favourably of the treatment. In any case, subcutaneous injections are too slow in their action; intravenous injections give the best results, as by this way the antitoxin reaches the nerve centres with extreme rapidity. Here also large doses of the serum should be employed (3 to 10 ounces), and repeated every day.

Sicard recommends the rachidian method. After withdrawing from 15 to 40 c.c. of the rachidian fluid, a similar quantity of serum is injected and the patient placed in a position to facilitate the flow of the liquid to the bulb—that is to say, the head and shoulders on a plane lower than the rest of the body. It goes without saying that during the whole of the treatment the patient must be kept free from any excitement and in a darkened room.

GERMANY.

Berlin, July 26th, 1913.

At the Gesellschaft der Charité Aerzte, Hr. Haemisch showed an apparatus that had been constructed for the purpose of enabling a man who had lost the use of his hands to write. He said that what he was about to show had a considerable practical significance. He had been of the opinion that such an apparatus was in existence, and when a few months ago he had a case in which the patient had lost complete use of his hands he had sent the man to Prof. Joachimsthal for the purpose of getting something arranged for him. The idea was that the teeth should be made use of, so that something could be held in the mouth and moved in such a way that the man would be able to write. Hr. Joachimsthal, however, told him that such a thing was new, and he could not see how it could be arranged in the polyclinic. He, however, put himself in communication with the dentist Hr. Grünberg, who in a short time produced the apparatus which answered the purpose and enabled the patient to write quite well. (Patient shown.) For a patient who had lost completely the use of hands to be able still to write, and in this way still to be able to communicate with the outside world in another way than by the limited range of speech alone was a great advantage, not only from a practical business point of view, but the psychical advantages also would be great.

Hr. Ohm showed an apparatus for the photographic registration of

Arterial and Venous Pulse, etc.

The apparatus gave a simultaneous registration of the arterial and venous pulse and the sounds of the heart. He hoped shortly to be in a position to show the diagnostic value of the apparatus and its methods of employment.

Hr. Buth followed with a contribution respecting the

Treatment of Recurrent Fever by Salvarsan.

He said that on February 2nd of the present year a Danish medical man was admitted into hospital. He had been actively engaged in the Servian campaign. On January 30th he left Valjewo in Servia in good health. On his way home he suddenly sickened with a chill on the way from Budapest. There were no rigors, but fever and a headache and a feeling of chilliness. The headaches were very severe. He had, as he thought, hallucinations of vision, and vomited frequently. On February 1st he reached Berlin and sought medical advice, with the result that he was sent into hospital. The diagnosis of recurrent fever was led up to by the patient's own statements that whilst in Servia he had seen several cases of the disease, and he suspected that he had become inoculated with the Obermeier's spirochætæ. He was supported in this by the fact that the prisoners of war amongst whom the disease was rife were infested by vermin—bugs, lice and fleas. As there were no facilities for bathing and no time to look after himself from the great amount of work there was to do, he could not keep himself free from the vermin. Moreover, in preparing a cultivation from blood from a patient suffering from the disease, he had pricked his finger, and he looked on this as the source of his infection. As a matter of fact, spirochætæ were shortly after found in the blood he was then about to examine when he pricked his finger. The diagnosis was therefore pretty clear. Of the other symptoms there were herpes on the lips and a thickly coated tongue, enlargement and tenderness of the spleen, and painful liver. There was also subicteric colouring of the skin and sclera, slight pain in the calves of the legs, great prostration. Hæmatologically the blood was normal. There was no leucocytosis. Albumen and urobilin were present in small quantity; diazo reaction absent, as it always was. From the point of view of treatment a grave omission had been made by the failure to give salvarsan at once. At midday on the 3rd, 0.6 gms. were given intravenously according to instructions. Two hours later there was a rigor with pain in the region of the heart; diarrhœa. After the injection the temperature rose to 40.3°, to go down the followlowing morning to 36.4°. The patient still vomited frequently, but felt himself better. In spite of several careful examinations of the blood no spirilli were to be found.

In considering the critical fall of temperature, its behaviour in Servia had to be taken into account. There the fall took place about the fourth or fifth day, and the relapse followed from the ninth to the tenth. The fall in the case of their patient on the third might have been the usual one for the Servian cases. The day following there was some tendency for it to rise, and it was thought that a relapse was about to take place, so another dose of salvarsan was administered. This was given on the 8th in a dose of 0.4 grm. Here also in about an hour there was a short rigor; the temperature after a time rose to 39°. but sank again; it had not gone beyond the normal since. The reconvalescence was an uninterrupted one. The spleen was no longer palpable. He was discharged quite well, and he had remained so, as he had written to the speaker to that effect. The curves that were shown were typical of the action of salvarsan. A sudden fall of about 4° took place.

Hr. Kraus thought that the rise of temperature that followed the infusion of the salvarsan was due to some want of absolute sterility in the preparation.

Hr. Döhrer said that sterilised saline solution from the apothecary's had been made use of, but it was always followed by fever, rigors and vomiting—(Hr. Kraus: The celebrated salt fever!)—that had led them to get their saline solution made in their own laboratory. Since then they had had no more such cases.

AUSTRIA.

Vienna, July 26th, 1913.

Radio-activity in Therapeutics.

At the recent meeting of the K.k. Gesellschaft der Aerzte in Vienna, a very full and extremely interesting and instructive discussion took place of the uses of "radiant energy" in therapeutics.

Dr. W. Falta expressed the opinion that the Becquerel-rays were equally effective in the treatment of uterine carcinoma, whether emanating from radium, thorium, or actinium; also that whether the alpha-, beta- or gamma-rays are employed, the same chemical and biological effects are produced. Highly active thorium X-preparations are able to oxidise certain organic substances. It has now been found, in the further pursuit of the research suggested by this observation, that the other radio-active substances—actinium, radium—in which the radiations of high activity are retained, or, as the investigations of Riel's clinic have shown, even the radio-active residue of the radium emanations produce corresponding chemical effects. He was also able to show that this result was also effected with equal energy whatever was the group of rays adopted. They took place when the alpha-rays and the feeble beta-rays were screened off; they also occurred with the use of pure alpha-rays and of polonium, which Stefan Meyer had prepared for use. As regards qualitative effects, all the rays, and groups of rays, gave the same results in these researches. But, as regards quantitative results, the researches of Charnas, of Zekner, and his son, agreed in showing a considerable difference. Observation of the spectrophotometric running-down of the decomposition of malachite-green showed that we can obtain as considerable a chemical effect from the employment of a few e.s. epsilon of actinium X as from that of 1,000 e.s. epsilon of thorium X. We also find that the chemical effects of polonium in the reagent-glass experiments are extraordinarily powerful. This fact is easily understood when we remember that the alpha-rays have a very limited province of jurisdiction; while the beta- and gamma-rays of actinium are mostly very weak in action; and those of thorium are, on the other hand, very hard. Now, all these, as in the case of the Becquerel rays, can produce chemical effects only being absorbed; that is to say, when their internal energy has been transmuted into some other form, either directly, or, as in the case of the gamma-rays, through an intermediate stage of conversion into weak, easily-absorbed beta-rays. In experiments with thorium X, it is also to be noted that the greater part of the internal energy of this body is not brought into use in the course of experimental procedure. All three groups of rays have accordingly identical chemical effects, so far as quality is concerned. With similar degrees of intensity they dissolve the molecular bonds; they hydrolyse, oxidise, and decompose colloid solutions. In quantitative reckoning, however, their effects are in the inverse ratio of their penetrating power. With regard to their biological effects the following fundamental law should be recognised. In small doses the effect is to increase the vitality, produce elevation of vital energy, increase of bio-chemical processes in the cells, with extinction of those which lead endothermally to reduction and synthesis; while with the use of large doses we have the limiting effect on synthesis, with simultaneaus increase of the reverse process in the foreground of observation. In the first place we find an increase in the process of growth and corresponding hyperplastic advancement; in the latter case we meet with limitation of the process of growth and relative destruction of tissues. Thus we find also with regard to the general biological effects: a similar qualitative effect, combined with a very different quantitative one—as regards the penetrating powers of the group of rays employed.

Dr. H. Marschik described his experience of the employment of radium therapeusis in the treatment of carcinoma of the larynx and of the pharynx. The results were not unfavourable, though complete success had not been obtained by him.

Dr. H. Schüler pointed out that, as in the case of light rays, the law of the alpha-, beta- and gamma-rays was that their intensity diminished in proportion to the square of the distance. Hence the full economic efficacy of radio-active substances could be obtained only when the exposed objects were placed in the closest possible proximity. On this account, of two equally effective filters the thinner should be chosen—all the more so from the fact that the thick metallic filters, as well as the thin, must be coated with gum, leather, etc., for the purpose of screening off the injurious secondary beta-rays. Unnecessarily thick filters diminish the gamma-rays—an undesired and unexpected diminution of the available radiant materials. According to the measurements of Meyer and Keetmann, in the case of mesothorium corresponding to the strength of 100 mg. $RaBr_2$ equivalents, a silver-gilt filter of 1 mm. thickness sufficed for the interception of the beta-rays. In the use of large quantities of mesothorium behind the Auer filter, and analogous methods, Schüler has not observed any mischievous effects of beta-rays. With such precautions, Redner has simultaneously employed with a patient, as maximum daily dosage, 100 mg. mesothor- and 85 mg. radium-bromid during 24 hours of a "cross-fire" procedure. The law of inverse squares also furnishes the most important starting point for application and dosage of radiant energy in the therapeusis of deep-seated structures; in this class of cases, absorption of the gamma-rays by the intermediate tissues has to be reckoned with, but the loss through this agency was found to be proportionately less than that chargeable to the influence of the law of inverse squares. The utilisation of a thin filter enabled him to construct an apparatus for endovesical radiation of the urinary bladder. (The application of the instrument was here demonstrated.) The procedure was not recommended for treatment of operable tumours, but for the recurrent and inoperable. The short time-period and limited histological experience had not yet given decisive results.

HUNGARY.

Budapest, July 26th, 1913.

THE MISUSE OF HYDROTHERAPEUTIC MEASURES.

DR. DALMADY FOLTAN, Secretary of the Balneological Society, believes that the mistakes in the application of hydrotherapeutic measures are the main reason why this branch of therapeutics has not been more favourably received by the medical profession. The necessary requirements he sums up as follows:—(1) A careful analysis of any deviations from the normal in the organs or their functions—*i.e.*, a careful clinical history; (2) a knowledge of the physiological action of thermic and mechanical stimuli; and (3) a thorough knowledge of the *technique* of the procedures. In febrile diseases the choice of the temperature of the water is entirely dependent upon its action on nerves, vessels and tissues, and it is a great mistake to use, at the beginning of the treatment, water at a very low temperature applied for a short time only and accompanied by only a slight amount of mechanical stimulation. Such baths should be merely cool, long continued, and followed by sufficient mechanical stimulation. In cases of collapse and cardiac weakness, where there is a high body temperature and cold extremities, it is necessary to apply cold to the trunk, and the extremities must be warmed by rubbing with warm alcohol or the application of hot packs. In administering sitz baths, care must always be taken to guard against the loss of heat from the uncovered parts of the body. It is essential that each case be studied on its individual merits, and Dr. Dalmady Foltán believes that the art of acquiring this habit can only be gained from a well-managed hydrotherapeutic clinic.

ON LEFT-SIDED GASTRIC PAIN.

At the recent meeting of the Budapest Interhospital Association, Dr. Benedict read a paper on the above subject. He pointed out that gastric pain occurring reflexly from disease of other abdominal viscera is most often referred to the right side, so that left-sided gastric pain, in the great majority of cases, signifies an affection of the stomach itself. The only two exceptions, fat necrosis of the pancreas and splenic abscess, are so rare that they can be disregarded. An ulcer situated at the pylorus is much harder to diagnose than one in the body of the stomach, since the former gives rise to pain on the right side, which often cannot be distinguished from the pain caused by cholecystitis. With ulcers of the antrum pylori the pain is accurately referred to the median line, just like the reflex abdominal pain caused by chronic appendicitis and that of a hernia of the linea alba. Tumefaction is exceedingly common with ulcers, since the muscularis and serosa will thicken and adhesions will readily form with the neighbouring organs, particularly the liver and the pancreas. A mass may thus be felt to the left of the median line, if the ulcer is situated in the middle portions of the stomach. It is very important to diagnose the case sufficiently early, since the end result will be an hour-glass stomach, which can only be treated by means of an operation. The history is rather characteristic: At first there is an attack of left-sided pain directly after eating, lasting several hours. Several months later there may be another attack, the stomach having been perfectly normal in the meantime. In six months or so the pain comes more often and lasts as long as twelve hours, and the irritability of the stomach increases. Finally, vomiting sets in half an hour after a meal. This is purely reflex, since a stenosis has not yet formed. The pain is now permanent, and vomiting occurs daily, but blood is found in only half of the cases. Operation is indicated if rest in bed for several weeks with hot applications and fluid diet does not result in a cure.

Treatment of Acute Coryza.

According to Dr. E. Baumgarten, late Professor of Rhinology, acute coryza may be successfully aborted by the following combination:—

Sod. salicylate, 30 grammes.
Pulv. Doveri, 3 grammes.

Mix and divide into 20 powders. Give at first every three hours, later two or three times a day.

CANADA.

Toronto, July 21st, 1913.

Annual Meeting of the Canadian Medical Association.

The forty-sixth annual meeting of the Canadian Medical Association was held in London, Ontario, on June 24th, 25th, 26th and 27th, 1913. The meeting was successful so far as the programme and quality of papers were concerned, although somewhat unsatisfactory with regard to attendance. Few more suitable places for such a meeting than London could have been found in Canada. The railway service, both from all parts of the Dominion and from the United States, is excellent, and London itself is a picturesque and thriving city. It well deserves its name of Forest City, the streets and roads being everywhere lined with shady trees. The programme was lengthy, and, on the whole, the papers read were interesting, dealing with questions of immediate concern to the medical profession.

The Presidential Address.

Dr. H. A. McCallum, of London, the President for the year, gave a strong presidential address. He said, in part, that a more active interest in the work of the Association should be taken by the members of the Canadian medical profession. It had done great service in doing away with provincialism and inaugurating great reforms of inestimable benefit to the profession and the public generally. With every practitioner in Canada a member, greater and more beneficent results could be obtained.

The Medical Profession and Nostrums.

Dr. McCallum laid stress upon the necessity for funds to rescue the Association from the exploitation and the commercial enterprise of certain drug houses. The chemical industry of Germany was carefully organised, and it was difficult to know what to accept and what to reject. Trained and scientific censors were needed to give advice and assist in shaping legislation to prevent the sale of nostrums. The promise of the Prime Minister of Canada, the Hon. R. H. Borden, that a portfolio of public health would be created in the near future had given great satisfaction among the members of the profession. Without this a pure food law or federal control of vaccines, serums and drugs would be impossible.

Specialism.

Praise was bestowed on the work of the Carnegie Foundation, but it was meeting with the same difficulty so common in German—that medical men were scientists first and practitioners afterwards. This was a reversion of the natural order of things that was not producing the best results. The outcome was that the medical student of to-day was burdened too much with scientific subjects and laboratory work without being grounded sufficiently in the fundamentals. This was a mistake, and the general practitioner suffered. The larger percentage of the students graduating to-day were going to specialise in surgery, and there was a grave danger that this branch of medical science would crowd the practice of medicine into the background. This was not in the best interests of the profession as a whole or the public. The lack of knowledge of the value of medicines made the practitioner as well as the public victims of the nostrum pedler. Dr. McCallum advocated the annual examination by competent medical men of every adult. School children were examined periodically, but the adult was never examined until sickness compelled him to consult a doctor. Insurance companies had adopted a plan of examining their clients annually, and in his judgment it would be good policy for all men and women to be thoroughly examined once in a year. The necessity for higher degrees and qualifications in medicine and surgery in Canada and the United States was insisted upon. The profession would be improved, and better results would follow. Incidentally, the low fees prevailing in many districts of the Dominion were referred to, and the hope was expressed that there would be a general levelling up in this respect. Dr. McCallum thought that more publicity should be given to the

Achievements of Medical Science.

Certain branches of the profession had pursued this course with much success. Great publicity had been given to the results of vaccination in the prevention of small-pox, and similar results would follow if wider publicity were given to vaccination against typhoid fever. The inroads of tuberculosis had been made public and the support of the people enlisted in stamping out this disease. Similar methods should be adopted in the case of cancer and other diseases. That the profession should not be made an arm of the Civil Service was stated to be the speaker's most emphatic opinion. Then, the public would not be protected against its own gigantic credulity, nor the profession purged of its abuses. A demagogue might arise at any time to attack the profession, and it was best to be armed and ready. In conclusion, he pointed to the wonderful service done by the profession, and hoped that this matchless progress would be continued.

Dr. T. S. Cullen, of Johns Hopkins University, Baltimore, gave the

Address in Gynæcology.

This address was rather an earnest plea for the vigorous prosecution of a popular campaign against cancer than an address in gynæcology. At the Congress of Clinical Surgeons of North America held in New York in November last, some of the more prominent surgeons present advised that a propaganda on popular lines should be at once undertaken for the purpose of informing the general public, and especially women, as to the early symptoms of cancer, so that the disease might be diagnosed and treated ere it had gained such a foothold as to be incurable. Dr. Cullen outlined the steps that had been taken to put this project into practice. It was decided that the proprietors and editors of influential daily journals and of popular magazines must be interested in the movement. Mr. Bok, the proprietor of the *Ladies' Home Journal*, Mr. Collier and Mr. McClure took active measures to disseminate knowledge as to the means of detection of the early symptoms of malignant disease far and wide. The conclusion was come to that in order to reach the ears of the masses, such information must be couched in clear and easily comprehensible language, and that therefore a tried popular writer would achieve this object better than a medical writer. A well-known popular writer was selected, who, after making himself well acquainted with the essential facts regarding cancer and its early symptoms, contributed a series of articles to a magazine of enormous circulation. According to Dr. Cullen, the results of this crusade have been most satisfactory, medical men from all parts of the United States having reported that large numbers of men and women, particularly of women, had come to them for diagnosis, and that in many instances where treatment had been considered necessary the outcome had been most encouraging. Dr. Cullen emphasised the need for interesting women in the movement, not only because women were more prone to the disease, but because the women would also look after the health of the men. The woman is the guardian of the health of the household. Dr. Cullen strongly insisted upon the value of a skilled surgical pathologist, and said that every hospital should possess such a man. Furthermore, he said that every medical man should have had a good training in surgical parthology. The address concluded with the advice to Canadian practitioners that they should initiate a campaign against cancer similar in character to that which had met with such success in the United States.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Insurance Act in the Highlands.

The Commissioners have issued their scheme for dealing with the mileage question in the Highlands. It is explained that the scheme is merely provisional and applicable only to the present year, pending arrangements to be made under the Highlands and Islands (Medical Service) Bill about to be introduced in Parliament. Mileage is to be reckoned by the distance along the usual route from the nearest doctor's house, no account being taken of the first three miles by land. Distance along a driving road is "normal mileage"; along paths not used for vehicular traffic, "special mileage." Fractions of a mile are reckoned at the nearest quarter above. To each county is allocated 1s. per normal mile, 2s. 6d. per special mile, and 4s. per water mile. The Insurance Committee shall distribute this sum among the practitioners on the panel who are entitled to participate in it, and in the allocation they may take into account the special circumstances of the case, *e.g.*, in very exceptional circumstances allowance may be made for distances of less than three miles, the sum to be allowed for each normal, special, or water mile, the facilities for conveyance, and the aggregation or segregation of insured persons on any doctor's list. Eventually, the intention is to distribute the available money as equally as possible on the Commissioners' scheme among the different counties, and then to allow each county to distribute its share as equitably as possible among the doctors, taking all local peculiarities into account. From a memorandum it would seem that a great deal of detailed work has been involved in drawing up this scheme. The Commissioners' inspectors obtained the addresses of all insured persons in respect of whom mileage would be payable, and then personally computed for each of them the number of normal, special, or water miles from the nearest doctor. From these data the amount due under the above scale was calculated at £8,220, out of the total grant of £10,000. The Commissioners are prepared to furnish the Committees with the records on which the calculations are based, so as to assist them in allocating their fund; in practice, Insurance Committees will probably find it convenient to adhere as nearly as possible to the method adopted by the Commissioners. The balance of the grant (£1,780) has been set apart to meet special charges in respect of medical benefit, especially as regards mileage for temporary residents.

Baldovan Institution for Mental Defectives.

The 58th annual report of this institution has just been issued. The directors state that as there is at last a prospect that modern legislation will find means of housing and employing the feeble-minded who have passed the years of childhood, it is more than ever the aim of such schools as Baldovan to prepare children for what they will have to do in after life. There is a subsidiary class of children for whom nothing but nursing can be offered; on the other hand, the great majority are capable of learning something—the school, the kitchen, the garden, the household, the laundry, the mechanic's shop, each absorbs its quota of children. During the year 26 pupils were admitted and 14 were discharged, the total number who passed through the Institution in 1912 being 225. The average age of admission was ten; it would be better to send pupils earlier. Six of the new cases were epileptic, one was paralysed, two had heart disease, one was a deaf mute, and one suffered from active tubercle. Less than half were in good bodily condition. Most cases were sent on account of poverty, not on account of their mental defect. This is not as it should be. Some enlightened School Boards send children on account of their mental defect alone—they are pioneers in a movement which is bound to come. Complaint is made of too frequent removal of children after a few months' residence. Interference of this kind with ordinary education would not be tolerated; it is futile to place the right of deciding about the education of a defective within the power of ignorant relatives. Half of the children discharged were unimprovable. Of the thirteen who died, five died from conditions depending on the nervous disease which was responsible for the mental deficiency, four from tubercle, three from epilepsy, two from thoracic disease, and one from hydrocephalus. The income for the year amounted to £5,695 19s. 9d., and the expenditure to £5,746 10s. 6d., leaving a deficit of £50 10s. 9d. The reports of the Lunacy Commissioners on the working of the Institution are satisfactory.

Edinburgh Royal Infirmary.

The managers have elected Mr. L. C. Peel Ritchie, F.R.C.S.E., and Mr. Denis Cotterill, F.R.C.S.E., to be assistant surgeons to the institution. There were a number of applicants for the two posts.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE B.M.A. AND ITS JOURNAL.

To the Editor of The Medical Press and Circular.

Sir,—In France the custom is when a Ministerial speech gains high approval to print it and placard it throughout the country. Your wise, temperate, and impartial leader of to-day—July 23rd—deserves a similar honour within the British Medical Association. The Association has been such a possible mighty power for good. It has achieved comparatively so very little towards the advancement, in any sense of the word, of the profession. This has not been the fault of any individual, or of any group of individuals. It has been due to the combined apathy of the great mass of members. The profession has undergone a rude shaking up over the Insurance Act, and the Association has at last been roused to the necessity of putting its house in order. Up to this crisis, the Association has remained for many years hardly much more than a co-operative society for the publication of a cheap medical journal. The journal has been inexpensive to members, but has been produced at a prodigious cost. It has not only absorbed a great part of the income from subscriptions; it has devoured nearly the whole of the vast sum derived from advertisements—from 50 to 80 pages a week at £5 to £8 a page. There can be no doubt that any business company or any business firm would be able to show annually a big balance on the right side as the result of such a successful enterprise. If the Association in this matter fails, it seems to show that there is something wrong somewhere. My opinion is that the *Journal* is far too bulky, and I would back my opinion as that of the great majority of members. The *Journal* has gradually grown so large that to hold it is a fatigue, to glance through it a labour. I speak for the men in any position in practice who are fairly well occupied. To the student or the idle man the *Journal* may no doubt form a great attraction. To every other class reduction of its size from one quarter to half would afford a great relief. It contains always a great deal that might well be left out. This comprises such things, among others, as ancient medical history, and editorial articles and paragraphs having very little relation to medical science or politics. Very few of the original communications of any sort deserve verbatim record. Most of them, including the epitome of literature, might with advantage be cut down to half or even a quarter of their present length. The same applies to reviews of books. The Supplement is largely made up of items referring to proceedings of divisions and branches, which might be compressed into a few lines. It is often almost as big as the whole *Journal* needs to be. Unless a practitioner is to become to the last degree shoppy and narrow-minded, his reading must not be confined to one or more medical papers. He must read the newspapers, and the local paper if he lives in the country, to inform himself of the affairs of the world, and the working of the authorities under which he acts. In order to prevent intellectual stagnation, he ought to have always on hand a bit of really good literature in the form of an ancient classic or a solid modern work, including some fiction and some poetry. If he does this justice to himself he cannot find time for a medical paper as big as the *Journal;* and it is not wonderful to see in many local practitioners' rooms the *B.M.J.* flung aside with the wrapper not even torn across. Condensation of the *Journal* to half the size must reduce the expense of producing it by thousands a year, whilst its vast circulation must still secure a full supply of advertisements at a high price.

This letter is already long enough. If you do me the honour to publish it I may perhaps later express my views as to the organisation of the Association and the means and methods of its working.

I am, Sir, yours truly,
An Obscure Member.

Brighton.
July 23rd, 1913.

REVIEWS OF BOOKS.

DISEASES OF CHILDREN. (*a*)

Dr. Robert Hutchison's book of lectures on the diseases of children is an old familiar friend, and we welcome it in its renewed youth of a third edition. Dr. Hutchison has taken the opportunity afforded by this new edition not only to revise the whole work, but also to add six new lectures. The lecture on "cœliac disease," one of the new additions, is particularly welcome. The history of this disease is very interesting. The conditions seems to have been first described by Gee in 1888, redescribed under the name of "acholia" by Cheadle, and later rediscovered by Prof. Herter in America. In spite of these descriptions, and of the fact that the disease cannot be considered particularly uncommon, still it is hardly mentioned at all in the text-books, and many medical men are quite unacquainted with it. In this case, too, ignorance is particularly unfortunate, since the disease is readily amenable to the correct treatment. We are glad to think that for the future such ignorance will be impossible, for everyone who is interested in the study of diseases of children is likely to read Dr. Hutchison's book. Beside this, there are two new lectures on the diseases of the respiratory system, one on hysteria in childhood, one on some of the diseases of the heart in childhood, and one on some common affections of the genito-urinary system. It is sufficient to say that the new lectures are quite up to the standard of the old, and without unduly increasing the bulk of the book they make it much more complete. We feel sure that Dr. Hutchison will have to prepare many more editions of his work before he has exhausted the interest of his readers.

LES ARRIERES SCOLAIRES. (*a*)

The subject of education—physical, mental, and technical (which perhaps may be regarded by the majority as a hybrid of the other two)—is admittedly one of the most important and excruciating of the present day. The fact that we are borne, willingly or unwillingly, on the advance wave of the torrential current of democracy, makes some profession (at least) of philanthropy an essential condition of existence. And, in order to the administration of philanthropy, a fair quantum of expert knowledge is absolutely essential. The quality of the foundations on which we are attempting to build—or rebuild—and the texture of the natural investments which we are trying to varnish—or patch up, or re-weave—must surely be studied with minute and successful care if we are to claim anything like righteous justification for our professedly skilled professional interference.

The present contribution to our knowledge (and dependent treatment) of the case of Nature's step-children is one of substantial value. The data, and conclusions thereon based, are all enunciated with the crystalline lucidity which so happily characterises the high-class literature and thought of our enviable Gallic neighbours. Our authors discuss causes under four headings—L'hérédité, le passé morbide, le milieu familial et pédagogique de l'infant arriéré. And their suggestions are far too numerous (and enlightening, even when not exactly convincing) for detailed discussion within the necessarily brief limits of a review. The volume will thoroughly well repay a careful perusal.

MEDICAL NEWS & PASS LISTS.

Medical Sickness and Accident Society.

At the usual monthly meeting of the Executive Committee of this Society the claims showed a decided decrease, and are now falling to their normal summer level. The past six months have been very heavy in this department, and the sum of £10,000 has been paid away. The satisfactory feature noted at this meeting was that the new business for June was double that for the same month of the preceding year, and the expansion of this important department is being well maintained during the current month.

It was reported that the Society's candidate for a foundation scholarship at Epsom College was again successful. The annual subscription of 100 guineas which the Society gives is instrumental in procuring a large number of votes, and these are always given to the son or relative of a deceased member of the Society. Since the annual subscription has been given, all the Society's candidates have, so far, been elected. This benefit is given, without extra charge, to members or their children, and has proved of great value. The subscription of 100 guineas to the Royal Medical Benevolent Fund has also been of assistance to the widows of members in obtaining grants of money when in financial distress.

National Association for the Prevention of Infant Mortality.

With the birth-rate steadily declining, and the infant mortality rate, though certainly exceptionally low last year, yet higher than it should be, it is not surprising that a record attendance is anticipated at the English-speaking Conference on Infant Mortality, to be held at Caxton Hall on August 4th and 5th. Practically every country flying the British flag is sending delegates, and there will be, in addition, a large contingent from America. Not only will the Governments themselves of the several Colonies and countries be represented, but also local authorities, hospitals, voluntary infant welfare associations, etc., in large numbers. The Local Government Board supplies, in Mr. Burns, the President, and in Dr.

(*a*) "Lectures on Diseases of Children." By Robert Hutchison, M.D., F.R.C.P. Third Edition. 8vo. pp. xii. and 404. London: Edward Arnold. 1913. Price 10s. 6d. net.

(*a*) "Les Arriérés Scolaires." Conferences Médico-pedigogiques, par le Dr. Marcel Nathan et Henri Durot, avec la collaboration de M. Gobron et de M. Friedel. Paris: Libraire Classique. Fernand Nathan. 1913.

Newsholme, one of the Chairmen of the Sessions, while Mr. Pease, Sir George Newman, Lady Aberdeen, and Dr. Charles Hodgetts (Medical Adviser to the Canadian Commission of Conservation) are Chairmen of other Sessions. Sir Charles Lukis, Director of the Indian Medical Service; Dr. MacCullogh, Medical Officer for the Province of Ontario; Assistant Surg.-General John Kerr, of the U.S. Public Health Service; Dr. Henry Coit, Chairman of the American Association for the Prevention of Infant Mortality; the Duchess of Marlborough; Sir Thomas Barlow and Sir Lauder Brunton, Chairman and Vice-chairman respectively of the National Association for the Prevention of Infant Mortality, which is organising the Conference, will be among those taking an active part.

The Welsh National Memorial to King Edward.

At the annual meeting of the Board of Governors of the King Edward VII. Welsh National Memorial Association for the Prevention and Abolition of Tuberculosis, held at Colwyn Bay on Saturday last, Mr. David Davies, M.P., presiding, an extract was read from a Government White Paper issued that morning announcing that, inasmuch as in Wales the income from the investments of the National Memorial Association was being applied towards the treatment of tuberculosis patients, the Treasury had made a grant in favour of the Association to the extent of one-half of the amount of the income derived from such investments. The President announced that the Association's income amounted to £6,300 per annum, and the grant therefore would amount to £3,150 per annum. A resolution was passed expressing gratification that the Treasury had recognised the principle of making such a grant.

A Manchester merchant, Mr. D. S. Davies, has presented to the Welsh National Memorial Association a piece of land near Denbigh, 244 acres in extent, and valued at £5,000, as a site for a proposed sanatorium for consumptives.

University of London.

The following have passed the M.D. examination for internal and external students:—

Branch I.—Medicine.—A. D. E. Bayliss, B.S., Univ. Coll. Hosp.; T. K. Boney, B.S., St. Bartholomew's; A. Burrows, B.S., London Hosp.; A. N. Cox, B.S., Guy's; G. S. Earl, B.S., St. George's; A. B. Fearnley, B.S., St. Bartholomew's; H. P. Hacker, B.S., B.Sc., King's Coll. Hosp.; C. H. F. Johnston, B.S., Charing Cross Hosp.; E. J. G. Jones, B.S., and D. Kennedy, B.S., Univ. Coll. Hosp.; W. J. O'Donovan, B.S., London Hosp.; Ellen M. Pickard, B.S., London (R.F.H.) Sch. of Med. for Women; C. McM. Wilson, B.S. (University Medal), St. Mary's.

Branch III.—Mental Diseases and Psychology.—J. A. Perdrau, B.S., Univ. Coll. Hosp.

Branch IV.—Midwifery and Diseases of Women.—A. C. S. Courts, B.S., and S. Forsdyke, Univ. Coll. Hosp.; A. W. Jones, B.S., St. Thomas's; Mary E. H. Morris, Lond. Sch. of Med. for Women.

Branch V.—State Medicine.—N. H. Walker, B.S., St. Bartholomew's.

Branch VI.—Tropical Medicine.—C. N. Davis, B.S., St. Bartholomew's.

The following have passed the M.S. examination for internal and external students.—

Branch I.—Surgery.—G. Jefferson (University Medal), Manchester Univ.; T. D. M. Stout, Guy's; J. O. D. Wade, Univ. Coll., Cardiff, and Charing Cross Hosp.; C. H. S. Webb, Middlesex Hosp.

Mr. Webb obtained the number of marks qualifying for the University Medal.

The Indian Medical Service.

The competitive examination for commissions in His Majesty's Indian Medical Service was held on July 21st, 22nd, 23rd, 24th, 25th and 26th, for which 22 candidates presented themselves. Sixteen candidates qualified, and six failed to qualify. The following is a list of the candidates who secured the twelve vacancies which were to be competed for:—

Sahib Singh Sokhey, M.A., B.Sc., M.B., Ch.B., Edin., 3,517; Atul Krishna Sinha, M.B.Calcutta, L.R.C.P., M.R.C.S., D.T.M. and H.Camb., 3,392; Subramanya Doraisamy, L.R.C.P., M.R.C.S., 3,198; James Findlay, M.A., M.B., Ch.B.Glasg., 3,167; Allan Seddon, M.B., Ch.B., 3,146; Jyotish Chandra De, M.B.Calcutta, L.R.C.P., M.R.C.S., 3,072; William Collis Spackman, M.B., B.S.Lond., L.R.C.P., M.R.C.S., 3,061; Nanalal Maganlal Mehta, L.M. and S.Bombay, L.R.C.P., M.R.C.S., 3,039; Charles Harry Powell Allen, L.R.C.P., M.R.C.S., 2,957; Peregrine Stephen Brachenbury Langton, L.R.C.P., M.R.C.S., 2,943; Robert Morrison Easton, M.A., M.B., Ch.B. Aberd., 2,893; Reginald Victor Martin, L.A., L.R.C.P., M.R.C.S., 2,878.

Royal College of Surgeons in Ireland.

The following candidates have passed the undermentioned examinations:—

First Dental Examination, May, 1913.—Edward C. Boursin, M. B. Fisher, Lazarus L. Glick, Martin D. Higgins, Arthur C. Holden, Walter G. Keys, Montague R. Mosbery, James J. Shevilin, George G. Tyson.

Final Dental Examination, May, 1913.—Charles S. Lafferty, John S. Smith.

Primary Fellowship Examination, July, 1913.—R. G. Blair, Hubert C. Carden, John A. Fretton, Herbert Graham, Mary E. Henry, G. T. Hingorani, James B. Magennis, Henry Ross, I.M.S., Jerome Suares, Wm. C. P. Smyly.

Final Fellowship Examination, July, 1913.—Capt. John L. Lunham, I.M.S., Michael McGrath, William G. Ridgway, William R. Watson.

Conjoint Examinations in Ireland.

The following candidates have passed the summer examination of the Royal College of Physicians and the Royal College of Surgeons:—

Preliminary Examination.—D. J. Baldwin, A. H. Boyd, A. J. Crean, M. Donohoe, G. E. Evans, W. Flynn, W. Fielding, S. A. Gailey, Miss E. Gleeson, W. F. Hughes, M. J. Hunt, Miss C. E. Kyle, A. F. Mallon, A. McCambley, R. G. J. McCullagh, E. D. Nolan, V. R. O'Connor, M. J. O'Riordan, Miss H. G. Rea (with honours), P. J. Sheerin, A. A. Townsend, and S. T. Wills.

First Professional Examination.—Arthur Briscoe, Moses Briscoe, Maurice J. Broderick, J. J. Crowe, Francis Daly, William Evans, J. Holland, Henry Hurst, Thomas P. MacDonnell, George F. Maher, Denis B. McEniry, Harold L. Mooney, B. J. Mulligan, Michael J. O'Connor, Marks M. Price, George C. E. Roe, James F. Seale, James G. Thornton, D. E. Young.

Second Professional Examination.—W. G. Thompson (honours), Miss Elizabeth Budd, John Coffey, B. J. Daunt, M. Dockrell, John A. Fretton, J. J. Hayes, B. Hirson, James McGuire, J. A. McKinnon, Miss Marjorie McMullen, Thomas Moore, Thomas F. Moran, J. P. Pegum, Patrick K. I. Ryan, P. J. Sheridan.

Third Professional Examination.—A. P. Adams, S. Barron, W. P. Cooney (honours), J. Dwyer, M. Fitzgibbon, E. G. Foley, S. E. Gordon, J. W. E. Graham, E. N. H. Gray, O. K. Kerrigan, M. J. Loftus, W. G. McConnell, M. Moran, T. O'Donoghue, L. S. O'Grady, G. M. C. Powell, L. M. Rowlette, R. A. Ryan, T. J. Ryan, T. H. Sarsfield, B. Scher, J. A. Watson.

Final Examination.—Patrick Ashe, John D. Cherry, Dominic F. Curran, Hugh A. S. Deane, James Devine, William St. L. Dowse, Thomas R. Elliott, Thomas Gray, Aloysius Humphreys, James Kearney, John Kelly, Francis P. Kennedy, Frederick J. M. Kennedy, William J. P. Lillis, Robert J. May, Patrick M. Moriarty, Edward J. B. Moynihan, B. J. Mullin, Daniel Mullin, Bernard Murphy, Charles McDonnell, Thomas B. Newman, Bernard J. O'Donnell, George E. Pepper, Robert Slaney, Trevor S. Smith, Geoffrey N. Smyth.

Diploma in Public Health Examination.—Miss Ma Saw Sa, F.R.C.S.I. (with honours), Fidelis Conceicao, L.M.S., Emanuel Prisnath Ghose, L.R.C.P. and S. Edin., Miss Singcha Hoashoo, L.R.C.P. and S.Edin., Francis Keane, M.B., R.U.I., Charles E. McNaught, M.D.Dub., Roger Ll. Williams, L.R.C.P. and S.Edin.

SUMMARY OF RECENT MEDICAL LITERATURE ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

Reduplication of the Second Sound.—Core (*Med. Chronicle*, June, 1913) discusses the value of this phenomenon as a diagnostic sign in mitral stenosis. In 173 patients with mitral stenosis there were 66.4 per cent. in whom reduplication of the second sound was audible somewhere over the præcordium. A presystolic murmur was heard in 38 per cent., and a combination of systolic and diastolic murmurs in 36.3 per cent. A systolic murmur either alone or in conjunction with other murmurs was heard in 83.9 per cent. of the cases. Core comes to the conclusion that the double second sound over the præcordium, other than physiological, is one of the most important and certain of the diagnostic signs of mitral stenosis that we possess. If such a doubling remains throughout all phases of respiration, if it is associated, even vaguely, with past rheumatic disease, and above all if it is conjoined with an accentuation of the first sound, the diagnosis of mitral stenosis is certain. The physiological reduplication of the second sound is in the great majority of cases only audible at the end of a deep inspiration, and never throughout the whole respiratory cycle. The doubling is generally rapid and the second element is feeble. K.

The Treatment of Diphtheria Carriers.—Rolleston (*Brit. Journ. of Children's Diseases*, July, 1913) discusses the value of the treatment for diphtheria carriers introduced by Schiotz, of Copenhagen, in 1909, with active cultures of staphylococci. Rolleston first reviews the writings of those who have already recorded their experiences of this method of treatment, and then gives the detailed history of ten patients who were treated by him in this manner. In carrying out this procedure, Rolleston procures a pure culture of the staphylococcus aureus, two or three loopfuls of which is incubated in a broth tube for eighteen to twenty-four hours. With this culture the palate, fauces, and in nasal cases the nostrils as well, are sprayed three or four times a day. After each spraying, swabs dipped in the culture are applied to the tonsils and surrounding parts. A culture is made from the throat before each application, and the treatment is continued till no diphtheria bacilli grow from such culture. An interval of a few days is then allowed to elapse, when a further culture is taken. If this culture is found to be negative the patient is discharged, but if diphtheria bacilli grow the treatment is begun again. In all Rolleston's cases a mild form of sore throat was produced within two or three days of beginning the treatment, an occurrence that was not reported in any of the cases hitherto published, and this sore throat was accompanied by more or less constitutional disturbance. The malaise was considerable, and quite out of proportion to the temperature, which, as a rule, was only slightly raised. The symptoms, however, both local and general, were of short duration, and were not followed by otitis or any other complication. The treatment involves some discomfort, and is not recommended till other methods have been tried and found ineffective, and, furthermore, it should not be employed until the later stages of convalescence. Of the patients treated by Rolleston, in six of the faucial cases the culture findings became negative within two to seven days after starting the treatment. In two nasal cases the treatment was ineffective. In all but two of the patients a mild form of sore throat was produced, but no complications followed. K.

Ankle-clonus without Gross Disease of the Nervous System.—Tileston (*Amer. Journ. of the Med. Sciences*), July 1913) examines the evidence for the belief that for a long time persisted that ankle-clonus is a positive sign of organic disease of the central nervous system. He shows that ankle-clonus, indistinguishable from the genuine, is more or less frequently found in the following conditions:—Acute infectious diseases, especially typhoid; chronic infections associated with marked toxæmia, especially tuberculosis of the lungs in the third stage; uræmia, shortly before and during the acute uræmic seizure; epilepsy, immediately after the convulsion; intoxication from certain drugs, such as hyoscine, ether and chloroform; excessive fatigue; exceptional cases of certain neuroses, such as neurasthenia, hysteria and paralysis agitans; psychoses in the stage of excitement; chronic articular rheumatism. Clonus due to toxic states may usually be distinguished from that of organic nervous disease by the absence of spasticity and of other signs pointing to organic disease, particularly by the absence of the Babinski and Oppenheim toe signs. An exception to the above rule is met with after the medicinal use of hyoscine and immediately after an epileptic attack, in both of which cases the Babinski and Oppenheim signs may be positive. K.

Tuberculosis in Its Relation to Pregnancy, Labour, and the Puerperium.—Lobenstine (*Amer. Jnl. Obs.*, lxvii., 4) considers the subject under six heads—(1) The effect upon the pregnant of an active tuberculous lesion. He concludes that with a healed tuberculous focus a case may proceed through pregnancy, etc., with little or no disturbance. Rapidly repeated pregnancies tend to cause a renewed outbreak. (2) Latent tuberculosis not infrequently becomes active. Mild active cases may stand the strain with little damage, but many will be aggravated. In severe cases the deleterious effects are without question in the majority, and in all advanced stages the cases terminate in an early death. (3) The effect of active disease on the offspring. Here the death-rate is shown to be very high, both at birth and during the first year. Large numbers of the children are born weak and poorly nourished, and even those that are apparently healthy at birth show a tendency to malnutrition. (4) What should be our attitude in regard to lactation? In known cases of tuberculosis, this is a menace to both mother and child, and the ultimate recovery of the mother is likely to be retarded. In the case of the child the danger is great and should not be allowed, even with the greatest supervision. In all truly active cases the ideal method is the isolation of the child. (5) Treatment of the mother. The general treatment is that ordinarily advised. The obstetric treatment is divided into four heads—(*a*) simple abortion; (*b*) abortion followed by resection of the Fallopian tubes; (*c*) abdominal or vaginal hysterectomy after removal of the fœtus; (*d*) artificial abortion followed by excision of the placental site. During the first three months abortion should be performed in all active cases without delay. In the absence of an active lesion this is not justifiable. Salpingectomy is urged in all early active cases. In cases of greater severity the abortion should be followed by hysterectomy. During the second three months operative interference should only be undertaken in those cases which are progressing, and it should include hysterectomy. The results after hysterectomy are shown to be vastly better than after abortion alone. (6) Tuberculosis and marriage. Tuberculous women should be advised not to marry until the disease is fully arrested. In early cases the probability of conception is increased, and in active cases it means an early death of the mother in a large percentage and a child predisposed to infection. The view of compulsory vasectomy and salpingectomy in active cases where marriage is insisted upon is put forward in conjunction with the question of dealing with other hereditary diseases. F.

Ectopic Pregnancy with Anomalous Tubes.—Huffman (*Surg., Gyn. and Obs.*, xvi., 5) has confined the discussion to the objective evidence, regardless of theories based upon clinical data. Twenty-six specimens were examined, but of this number only ten could be examined for anomalies with certainty, and of these seven were associated with gross malformations. From the result of these studies there is ample support for the theory that ectopic pregnancy is caused by imbedding areas which were misplaced during the maldevelopment of the Müllerian ducts. F.

Proctolysis.—Trout (*Surg., Gyn. and Obs.*, xvi., 5), from a study of nearly 1,000 cases and the replies received from a number of hospitals, concludes that following the directions of the majority, and using the amount of fluid said to be absorbed by the rectum, would result in forcing into the patient in 24 hours as much salt as a normal individual would consume in one month. Water has been employed in over 1,000 cases, and there has been no evidence of destruction or irritation of the epithelium. Seven cases developed albuminuria with salt solution, and this disappeared in 24 hours with plain water. The majority of the patients who complained of thirst were those to whom salt was being given—viz., 112 to 9; and the water cases were found to take one-third more fluid than the saline, while the latter required nearly twice as much water by the mouth to allay thirst. The administration of either saline or plain water is shown to decrease nausea and thirst as compared with cases treated without either. The use of plain water is considered preferable to saline, and some reported cases of toxic effects produced by saline are recorded in support of this view. F.

Local Anæsthesia in Fractures and Dislocations.—Braun (*Med. Review*, May, 1913) injects a 1 per cent. solution of novocaine-suprarenin from several different points and in many directions, so that it is thoroughly distributed about the lesion. When the amount of displacement is considerable, the ends of the fractured bone require separate anæsthesia. After a dislocation the anæsthetic is injected around and into the joint. The writer has treated 50 cases of fracture or dislocation by this method, as well as numerous dislocations of the fingers and compound fractures of the arm by anæsthesia of the brachial plexus. In one case of backward dislocation of the elbow, and similarly in another of supracondylar fracture, the anæsthetic was injected through the back of the triceps into the joint, as well as into the joint from both lateral aspects. In 15 cases of dislocation of the shoulder, anæsthesia of the plexus was induced in ten, and injections round the joint were given in five. The former method is the better. Although in one case the dislocation had lasted for weeks it was replaced without difficulty. Several fractures and dislocations of the lower limbs were satisfactorily anæsthetised by local injections, including two cases of backward dislocation of the knee-joint. The amounts of solution used in the knees were respectively 35 and 40 c.c. Two cases of dislocation of the hip were treated. In a sciatic dislocation a long needle was introduced at two points in the gluteal region, and 25 c.c. were injected over the femur and 20 c.c. into the acetabulum. As the femur was no longer a guide to the acetabulum it was disregarded, and the anterior superior iliac spine of the ilium was used as a landmark, immediately behind which the needle was inserted. The point of the needle followed the surface of the ilium until the acetabulum was reached, an innominate bone being held by the side of the patient so as to guide the surgeon as he introduced the needle. The injection was almost immediately followed by relaxation of the previously rigid muscles, and in ten minutes reduction of the dislocation was easily effected. In an obturator dislocation of 48 hours' standing injection about the head of the femur, acetabulum and great trochanter produced complete anæsthesia in five minutes with relaxation of the muscles, and the dislocation was reduced at the first attempt. The writer has had no accidents with this treatment of fractures and dislocations. For the arm he considers injections into the brachial plexus preferable to injections into the injured part, the reverse holding good in the lower limb. He finds reduction of a dislocation easier under a local than under a general anæsthetic. S.

Nauseating Cough in Phthisis.—After prolonged and careful investigations on this question, Dr. H. Paillard has come to conclusions which differ from the classical views. In regard to ætiology, several factors have to be considered—(1) the overloading of the stomach; big meals bring on Morton's cough, therefore the patient must be directed to adopt fragmentary feeding. (2) The fatigue after the meals; this cough is often met with among labourers, workmen, etc., but is not frequent among well-to-do people who can take a complete rest after meals. (3) The period of the disease. Morton's cough is much more common in the first stages of phthisis. (4) The localisation of the pulmonary lesions. It is very common in the common phthisis of the apices, but very rare when pleurisy has already prevented the movements of the left side of the diaphragm. (5) The "status dyspepticus." This was considered by all the classical writers as an essential factor, but the author thinks it is a mere accessory because it is often absent, and furthermore cough is not at all constant in all dyspeptic patients. There are three varieties of Morton's cough: the most typical is the variety which follows on the onset of phthisis; the cough of the later stages of the disease is less frequent, less regular, and more painful. Lastly, the variety which bears no relation to meals but occurs in the morning, especially in patients with pharyngitis, and is not at all special to consumptive patients. The author insists on the feeling of breathlessness which appears after meals and before the cough. The pathogeny of Morton's cough has been very much discussed, and the author discusses it again. He is in favour of the mechanical origin of this cough, and shows how Peter's theory is vague and feeble. According to Paillard the vomiting is due, as in whooping cough, to the jolts and jerks of the cough, and in this respect he insists on the importance of the condition of the diaphragm in the causation of Morton's cough. Experimentally, he has noticed that the fixation of the left side of the diaphragm almost prevents vomiting; clinically he has seen that Morton's cough seldom occurs in patients whose left side of the diaphragm has been fixed by a former pleurisy. Conversely consumptive patients whose left diaphragm has normal or exaggerated movements when breathing or coughing are very often afflicted by the stiffness of the diaphragm, and the "thoracic aspiration" (Arnozan) is deficient; in the second case, *i.e.*, exaggerated movements, the stomach is directly injured and the "thoracic aspiration" is maximum. As to treatment, H. Paillard recommends to give after each meal a few whiffs of oxygen; these inhalations may be repeated if necessary; they relieve the dyspnœa which is so common after meals and reduces the desire to increase the expansion of the thorax and diaphragm. Thus the stomach is given sufficient rest to evacuate its contents at a normal rate. This method, as well as the recommendations which we have seen about ætiology, has given excellent results.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

Reprints.—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

P. W. R. (Fortis Green).—The price of radium at the present time is about £16,000 per gramme, or the equivalent of £480,000 per ounce, and its production is a very slow process

THE "MEDICAL DIRECTORY" FOR 1914.

To the Editor of The Medical Press and Circular.

Sir,—The annual circular for The Medical Directory will be posted to the members of the medical profession on the 31st inst. If by any chance the circular is not received within a few days of the date of posting, we shall be pleased to forward a copy on request. We trust that all practitioners will make their returns to us promptly, in order that the entries may be as accurate and up to date as possible.

The Directory will, as usual, be published a few days before Christmas, and to this end we ask for the co-operation of the profession.

We are, Sir, yours faithfully,
J. and A. Churchill.

7 Great Marlborough St., London, W.,
July 26th, 1913.

Mr. R. P. (London, S.E.).—Condylomata acuminata are not necessarily specific in character. The growths are probably best removed by touching with the galvano-cautery under general anæsthesia. If preferred a local anæsthetic may be used and a trial be given of cautious painting with the solution of acid nitrate of mercury, followed by a generous powdering with boric acid, starch and zinc oxide.

LEMONADE POWDER.

The following is a good recipe for a palatable substitute for fresh lemons and may be recommended as an excellent cooling beverage:—

Citric acid, ½ ounce.
Tincture of lemon, 6 dr.
Sugar, 1 lb.
Boiling water to 2 pints.

—*The British and Colonial Druggist.*

F.R.C.S. (West Riding).—The older method for the detection of blood-stains with guaiacum resin, yielding a deep blue coloration, has been largely superseded, or rather, confirmed, by the application of several other colour tests, such as the aloin reaction. A solution of isobarbaloin gives an intense raspberry-red coloration, first observed by A. Klunge, and afterwards studied by Prof. Edward Schar, of Strassburg.

MEDICAL INSPECTOR OF FACTORIES, SALARY £500 to £700.

The Home Secretary asks us to announce that he is about to appoint an additional Medical Inspector of Factories at a salary of £500 per annum, rising by annual increments of £20 to a maximum of £700. The appointment will be subject to the usual Civil Service conditions as to retirement, pension, etc. The Medical Inspector will be required to undertake medical inspection, under the direction of the Senior Medical Inspector, in factories, workshops and other places under the Factory Acts in any part of the United Kingdom, and to reside in such place as the Home Secretary may from time to time direct. Candidates should be between the ages of 25 and 40, and applications should be addressed not later than August 15th to the Private Secretary, Home Office, Whitehall, London, S.W., from whom forms can be obtained. Recommendations or testimonials will only be considered if based on personal knowledge of the candidates and candidates are advised not to seek political or social influence, which will prejudice rather than assist the candidature.

Mr. R. Brown (Chiswick).—It is well known that the X-rays possess a malign influence upon the reproductive organs. Manfred Fraenkel found that in the case of guinea-pigs the third generation lost the power of reproduction, even though the original parent alone had been exposed to the rays. The use of an appropriate shield will, however, prevent any injurious effects, such as you have apprehended.

CONFERENCE ON INFANT MORTALITY.

The English-Speaking Conference on Infant Mortality organised by the National Association for the Prevention of Infant Mortality, will be held at the Caxton Hall, Westminster, on August 4th and 5th, under the presidency of Mr. John Burns. Delegates will attend from all parts of the British Empire and from the United States. The chairmen of the sessions will be Dr. Newsholme (Medical Officer of the Local Government Board), Mr. Pease, Sir George Newman, Lady Aberdeen, and Dr. Charles Hodgetts (medical advisor to the Canadian Commission of Conservation). Among those who have promised to take an active part in the proceedings are Sir Charles Lukis (Director of the Indian Medical Service), Dr. MacCullogh (Medical Officer for the Province of Ontario), Assistant Surgeon-General John Kerr (United States Public Health Service), Dr. Henry Coit (Chairman of the American Association for the Prevention of Infant Mortality), the Duchess of Marlborough, Sir Thomas Barlow, and Sir Lauder Brunton. Programmes of the Conference may be obtained from the Secretary of the Association, 4 Tavistock Square, W.C.

Appointments.

Boyers, Hedley, Assistant House Surgeon at the West Bromwich and District Hospital.

Cates, Joseph, M.D.Lond., D.P.H.Cantab., Medical Officer of Health of the County Borough of St. Helens.

Hunt, Matilda, M.D.Lond., Clinical Assistant and Assistant to the Gynæcological Department at the Royal Free Hospital.

Kann, Miss A. L., M.B., B.S.Lond., Anæsthetist to the New Hospital for Women, and Clinical Assistant and Assistant to the Throat, Nose, and Ear Department at the Royal Free Hospital.

Mandrana, K. C., M.R.C.S., L.R.C.P.Lond., House Surgeon at the Italian Hospital.

Moss, Helen I., M.B., B.S.Lond., Assistant Anæsthetist to the Royal Free Hospital.

Radcliffe, Frank, M.D.Vict., Honorary Acting Surgeon to the Oldham Royal Infirmary.

Richardson, A., M.B., B.S.Lond., F.R.C.S.Eng., Surgical Tutor in connection with the Medical School at the University of Leeds and Surgical Registrar to the General Infirmary.

Vacancies.

Canterbury Mental Hospital.—Assistant Medical Officer. Salary £160 per annum, with board, lodging, washing, and attendance. Applications to the Medical Superintendent.

Carlisle Dispensary.—Resident Medical Officer. Salary £150 per annum, with apartments (not board). Applications to the Hon. Secretary, Mr. G. A. Lightfoot, 23 Castle Street, Carlisle.

County Borough of Oldham.—Assistant Medical Officer of Health. Salary £260 per annum. Applications to J. H. Hallsworth, Town Clerk, Town Hall, Oldham.

Swansea General and Eye Hospital.—House Surgeon. Salary £100 per annum, with board, washing, and attendance. Applications to W. D. Hughes, Secretary.

Herts County Asylum, Hill End, St. Albans.—Second Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing. Applications to the Medical Superintendent, Herts County Asylum, Hill End, St. Albans.

Warwickshire County Council.—Assistant County Medical Officer of Health. Salary £250 per annum. Applications to A. Bostock Hill, M.Sc., M.D., 14 Temple Street, Birmingham.

Kent County Asylum, Maidstone.—Fourth Assistant Medical Officer. Salary £200 per annum, with furnished quarters, attendance, coals, gas, garden produce, milk, and washing. Applications to Medical Superintendent, Asylum, Maidstone.

Worcester General Infirmary.—House Physician. Salary £120 per annum, with board, residence, and washing. Applications to William Stallard, Secretary, Worcester Chambers, Pierpoint Street, Worcester.

Holloway Sanatorium Hospital for the Insane, Virginia Water, Surrey.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, laundry, and attendance. Applications to the Medical Superintendent.

Births.

Blomfield.—On July 23rd, at 217 Queen's Road, Peckham, S.E., the wife of Alfred Blomfield, M.R.C.S., L.R.C.P., of a son and daughter.

Carmichael.—On July 22nd, at 40 Palmerston Place, Edinburgh, the wife of E. Scott Carmichael, F.R.C.S.E., of a daughter.

Evans.—On July 25th, at 101 Princes Avenue, Hull, the wife of Harry Loft Evans, M.R.C.S., L.R.C.P., of a son.

Gandy.—On July 23rd, at Norwood, the wife of E. Worsley Gandy, M.R.C.S., L.R.C.P., of a daughter.

Gaster.—On July 24th, at Horley, Surrey, the wife of Sidney Gaster, M.R.C.S., L.R.C.P., of a son.

Grunbaum.—On July 26th, at 92 Portland Place, Doris, the wife of Otto Grunbaum, of a daughter.

Keeling.—On July 23rd, at Attleborough, the wife of George S. Keeling, M.D., of a son.

Palmer.—On July 22nd, at 96 Marine Parade, Worthing, the wife of A. S. Morton Palmer, M.A., M.D., B.C., of a son.

Shapland.—On July 25th, at Burnside, Exmouth, the wife of Dr. J. Dee Shapland, of a son.

Spiers.—On July 25th, at 232 Old Kent Road, S.E., the wife of T. Orr Spiers, M.D., of a daughter.

Waldron.—On July 22nd, at 49 Lauderdale Mansions, W., the wife of Derwent H. R. Waldron, M.B., C.M., Barrister-at-Law, of a son.

Wharry.—On July 24th, at Whitstone Head, Holsworthy, North Devon, the wife of Robert Wharry, M.D., of a son.

Marriages.

Chambers—Buchanan.—On July 26th, at Christ Church, Shooter's Hill, Kent, Dr. W. J. Chambers, of Calgary, Alberta, Canada, to Olive Watson, daughter of Charles Buchanan, of Lloyd's Register.

Dingwall-Fordyce—Warren.—On July 16th, at St. Paul's Church, Ramsgate, A. Dingwall-Fordyce, of Culsh, Aberdeenshire, M.D., F.R.C.P.Edin., to Bessie Ianthe Sutherland, widow of Captain Frank Warren, R.A., daughter of Dr. John Sutherland Gunn, I.M.S.

Finn—Bates.—On July 23rd, at St. Michael's, Chester Square, Allan Rigden Finn, M.D., F.R.C.S., youngest son of the late Mr. G. W. Finn, of Westwood Court, Faversham, Kent, to Jeanie Victor Bates, only daughter of Mr. and Mrs. Isaac Bates, of 56 Blenheim Gardens, N.W., and Wilmington, North Carolina, U.S.A.

Mawhood—Peel.—On July 23rd, at St. Paul's Church, Bedford, Reginald Hawksworth Mawhood, M.B.Cantab., F.R.C.S.Eng., of Chalcots, Ascot, son of Mr. and Mrs. John Mawhood, of Oak Mount, Sheffield, to Phyllis, eldest daughter of the late Mr. E. Lennox Peel and Mrs. Peel, of St. Andrew's Road, Bedford.

Deaths.

Gooding.—On July 27th, John Callender Gooding, M.D., M.R.C.S., of Stanmer House, Cheltenham, in his 76th year.

Groves.—On July 19th, suddenly, at The Lindens, Woodford Green, William George Groves, M.R.C.S., L.R.C.P., M.O.H., in his 78th year.

McInerney.—On July 23rd, at Abertillery, Mon., James Joseph McInerney, L.R.C.P. and S.I., L.M., aged 36.

Wharry.—On July 26th, at Whitstone Head, Cornwall, Marian, the wife of Robert Wharry, M.D., aged 41 years.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, AUGUST 6, 1913. NO. 6.

NOTES AND COMMENTS.

The International Congress of Medicine.

After an interval of thirty-two years, the Seventeenth International Medical Congress, which is held every four years, meets in London to-day. H.R.H. Prince Arthur of Connaught, as the representative of H.M. the King, under whose patronage the Congress is held, will open the proceedings at the Albert Hall at 11 a.m. this morning. A series of important addresses forms part of the programme of this most imposing gathering, for it is safe to say that London has never before witnessed such a galaxy of medical and scientific talent congregated within the Metropolis. The greater number of the meetings will be held within the ancient and royal borough of Kensington, within whose confines are the Albert Hall, the University of London, the Imperial College, the Royal Schools of Science and Art and the Central Technical College. In addition to these stately buildings the Royal Society of Medicine, the Royal College of Physicians of London, the Royal Army Medical College at Millbank, the Royal Dental and St. Thomas's Hospitals are also offering accommodation for sectional meetings. When Sir James Paget was President of the Congress at the London meeting in 1881, it may be recalled that there were 3,182 members and 15 sections. This year, under the Presidency of Sir Thomas Barlow, there will be about 5,000 members, and the work will be carried on in 23 sections and three sub-sections.

Honour to whom Honour.

THE address in medicine is to be delivered to-day at 5.30 p.m., in the Albert Hall by Professor Chauffard, of Paris, while that on surgery will be delivered to-morrow at 2 p.m., by Professor Harvey Cushing, of Harvard University, well known for his work on the pituitary and pineal glands. The distinguished German *savant,* Professor Paul Ehrlich, of "606" fame, will deliver the address in Pathology on Friday, August 8th, at 2 p.m. Next week Professor W. Bateson, F.R.S., addresses the Congress on Heredity, on Monday, August 11th, at 2 p.m., while the President of the Local Government Board, the Rt. Hon. John Burns, M.P., will deliver the address on Public Health on Tuesday, August 12th, at 3 p.m. It is reported that no less than one hundred formal discussions on set subjects are to take place at the sectional meetings, and no less than six hundred papers have been accepted, in addition to numerous demonstrations and exhibitions of cases and specimens. Medical science has made great strides during the last three decades, hence the increased number of the sections that are necessary for carrying on the scientific work of the Congress. Radiotherapeutics, serum and vaccine-therapy and tropical diseases will provide fresh themes for discusson, while, at the same time, many of the older problems will still find a place in the various debates. It is good to have the presence of those amongst us whose names are household words, men of European, nay, of imperial and international fame, men whom the citizens of London as well as the whole medical profession delight to honour. Whatever the outcome of an International Medical Congress may be from the scientific aspect, one thing is certain, namely, that the welfare of humanity as well as the cause of practical medicine, will be greatly promoted thereby.

Dr. F. Koch, of Berlin.

IN its issue of July 30th, *Truth* calls attention to a point that demands immediate investigation by the Executive of the International Medical Congress. On page 256 is reproduced a letter from Mr. C. H. Willi, who is stated to carry on an Institute of Facial Perfection at 475, Oxford Street, London, to a gentleman who had answered an advertisement. The letter announces that Dr. F. Koch, the celebrated Berlin surgeon, "pioneer of facial surgery, discoverer of new methods of correcting unsightly noses, and inventor of many new and important surgical instruments, author of the book, "Disfigured Noses and Their Correction," which I (Mr. C. H. Willi) sent to you some time ago, will be present at the meeting." The letter further says that Dr. Koch will lecture upon the latest achievements with relation to the improving and correction of the shape of the nose, the lecture being illustrated by limelight views and demonstrations of patients who have been successfully treated. "It may interest you," he adds, "to hear that Dr. Koch will also be in London from July 15th to perform nose corrections at my institute." It is impossible to believe that a member of the International Congress of Medicine could be found associating himself with an unqualified individual conducting business of this nature in the manner indicated.

Chapter and Verse.

YET *Truth* gives chapter and verse for the incident. In any case, it seems incumbent on the Council of the Congress to take prompt action in the matter. In the doubtful event of Dr. F. Koch, of Berlin, being really a qualified medical man and a member of the Congress, investigation would be desirable, and we venture to think, inevitable, with a view to disciplinary action both in Germany and in the United Kingdom. If, as seems not improbable, there is nothing to prevent a German surgeon from performing operations in Engand, there is, nevertheless, a moral obligation due to the Congress, and doubtless a certain control over the ethical actions of members vested in the hands of the Executive. On the other hand, should the statements by Mr. C. H. Willi regarding Dr. Koch's relations to the Congress and the limelight lecture and the performing of operations at Mr. Willi's institute prove to be not founded in fact, then the Congress might be expected seriously to consider the legal aspects of the affair. In the letter above quoted Mr. Willi invites his correspondent to attend the lecture at the Congress, and offers to send him "a ticket free of all charge." It may be safely assumed no one will be admitted to any Congress meetings without producing convincing evidence of his *bona fides* as a member or a specially invited or privileged visitor.

Attack on a Dublin Hospital.

Nothing is taken up with such zest by the public as an attack against a purely charitable institution, especially when that institution is a hospital. Every few months some enterprising journal with more knowledge of the public than of the subject fastens on some fact which when misstated appears a criminal offence. We do not blame lay people for stirring up such so-called scandals, we smile in a pitying fashion at their lack of insight. When, however, those who know or ought to know the conditions make serious allegations, our indignation is aroused. A patient applied for admission at Jervis Street Hospital. He was examined and found to be suffering from a chronic disease, which though requiring treatment did not require urgent attention. As there were no vacant beds in the hospital, the patient was sent to the North Dublin Union, to which he was admitted, and where he died two days later. The visiting surgeon to the Union refused to sign the death certificate, giving as his reason that a rumour had reached him that the patient had been turned out of a hospital in a dying condition. Hence followed great commotion in the public Press regarding the cruelty of refusing admission to dying patients, and the callousness not only of the staff of the hospital concerned but of all hospitals, the usual arguments from the particular to the universal being flung broadcast. To act thus on facts is often justifiable, but to rouse public resentment because of rumour is not. A telephonic communication would have settled the matter in a few minutes. As it was, an inquest was held. The result of going into the facts is obvious—the jury found that the hospital authorities and the medical staff were blameless in the matter. They also considered that the visiting surgeon to the workhouse should have signed the certificate. With both points we are in entire agreement.

Buried Talent.

In making the awards for the Raymond Horton-Smith Prize, the M.D. Degree Committee of the University of Cambridge is reported to have placed on record their appreciation of the high standard attained by most of the theses submitted for the M.D. degree. They further state that many of these documents, representing, as they do, a vast amount of clinical investigation on obscure diseases or of original laboratory research, ought to be published. With this recommendation we fully agree, for little practical good can accrue, except to the author, from the most learned thesis, embodying the result, perhaps, of some years' patient observation or research, if it be buried among the archives of a University library. For the sake of medical science the accepted theses for the degree of Doctor of Medicine in all Universities should be published and copies placed in all the principal medical libraries in the United Kingdom. Such a collection of monographs could not fail to prove of the utmost value to students, practitioners, and specialists. Furthermore, we might suggest that the Paris Theses and other Continental monographs of a like nature, might also be rendered available in all the medical libraries, instead of being confined to one as, we believe, is at present the case.

LEADING ARTICLES.

THE ETHICS OF THE PRESS NOTICE.

The confused and often contradictory state of the unwritten laws that govern the ethics of the medical profession in the United Kingdom is at once apparent to those who pay any attention to the matter. It is, in fact, a subject of continual sarcasm to those lay journals which appoint themselves censors of society. The weak points in the professional armour are, first, the absence of any definite rule regulating the publication of signed communications concerning medical matters in public journals, and, secondly, the absence of any machinery for the enforcement of any common standard of conduct amongst medical men. The outcome of this undesirable state of affairs is a certain amount of injustice to some individuals, and of open defiance by others. It would, of course, be absurd to say that no medical man is to address the public upon professional matters, but, while it is difficult on the one hand to set forth precisely how far he may go in that direction, it is, nevertheless, easy in many cases to say decisively when he has overstepped the dimly indicated boundary line laid down by unwritten tradition. An instance in point may be taken from the columns of a London daily newspaper, in which last week appeared an article on cancer. It was written beneath the name of a well-known physician, who has long been recognised as an enthusiastic investigator of the effects of diet in health and disease. His general proposition, so far as can be gathered from a careful perusal of the article in question, is that, according to the published work of certain recent authors—namely, the Hon. Rollo Russell, Mr. H. C. Ross and Dr. J. W. Cropper, cancer is more or less certainly the product of wrong feeding. The writer of the article says that side by side with the increase of cancer we have a corresponding increase in broncho-pneumonia, anæmia and Bright's disease; to which he adds "to-day we know that those diseases are the result of wrong and unnatural food." Neither the views as to the causation of cancer or of the other morbid conditions mentioned would be accepted by the vast majority of medical men. The theory thus advanced, therefore, is contentious and tentative to a degree, and if offered to laymen who are unable to test the truth of the probability may lead to much disappointment, waste of valuable time in seeking established remedies, and monetary loss. In short the publication of theories of this kind by medical men in lay journals cannot be regarded as a wise or dignified proceeding. As things stand in the medical world, however, there is no one to say yea or nay to any member of the medical profession who chooses to air his pet theories in public. The writer of the article above alluded to is physician to a London hospital, and is a man of distinction in his private and professional life. If his publication is justified by tacit professional consent, then every sort of signed communication by any medical man must be equally condoned. If there is to be a rule it must apply all round. There can be no fixing one standard for this medical man and a different one for that, as appears to be suggested by a glance over the names of many eminent medical men who are given to sending signed communications of various kinds to lay newspapers. Another somewhat kindred point of ethics is raised by the lay notices of medical papers read at medical meetings and congresses. Some of the papers read at the Sections of the British Medical Association at Brighton were more or less fully reported and commented upon in the daily newspapers. This occurrence must either be or not be in accordance with medical ethics. At any rate, it has the apparent sanction of the Association itself, for lay newspaper reporters were present in the various sections with the express sanction of the Executive as signified in the shape of official Press tickets. It is obvious that if a reporter be present he has come for the purpose of reporting to his journal, and that the responsibility for the subsequent publication in the daily Press of any medical papers and discussions must rest not with the speakers but with the Association, which has permitted the presence of public reporters. Indeed, were the principle of exclusion of purely medical matters from public Press notice pushed to its logical conclusion the chief addresses of the British Medical Association meetings would be sternly suppressed. The address in medicine, for instance, this year dealt with the highly technical subject of the internal secretions, but it was, nevertheless, widely noticed throughout the public Press of the kingdom. The whole matter of lay publication is riddled with inconsistencies, and it would be well for the British Medical Association to adopt some clear and reasonable policy with regard to its own members. Were the General Medical Council a less academic and more practical body, an appeal might be made to them for light and guidance upon a somewhat perplexing problem.

CURRENT TOPICS.

The Abuse of Prescriptions.

Surprises are always cropping up in the world of politics. A Bill has been introduced into the House of Lords by Lord Lamington to prevent prescriptions containing poisons from being dispensed a second time without authority from the medical man. The matter is one of much greater difficulty than appears on the surface. In the first place, the prescription belongs to, and becomes the property of the patient who pays for it. As such, therefore, the possessor is entitled, of course at his own risk, to make use of it when and how he pleases, whether containing a poisonous drug or not. It is well known that a common practice among certain patients is to hand a prescription from which they have derived benefit to other ailing persons, on the mere chance of good resulting. This may be legitimate, but it is not wise, and it is evidently the object of Lord Lamington's Bill to render illegal this reprehensible procedure. Let it be imagined, however, the confusion to which such a proposal, were it to become law, would lead. The effect of it would be bad for the patient and worse for the doctor. The patient would naturally resent having to visit the latter upon every occasion that the medicine required renewal, while the doctor would be requested to omit everything from his prescription which would render this liability unavoidable. Thus a limit would be placed upon his therapeutic armamentarium, and useful drugs which come under the poison schedule would practically cease to be prescribed. Strychnine, for example, is a scheduled poison. Does the proposed Bill imply that a mixture containing five minims of the liquor strychninæ would require to be endorsed by the medical man upon every occasion that it was prepared? It seems to us that the Poisons Act already in force is quite capable of dealing with the difficulty to which attention has been publicly drawn. It is surely within the power of the chemist, under this Act, to refuse to dispense poisonous drugs which he has reason to believe are being used illegitimately. The matter is one of small detail. The date of the dispensing of every prescription is usually affixed to the document; after, say, the third date so appearing without any evidence of reference to the prescriber a chemist might refuse to supply the drug. Obviously there was no intention to invalidate the Poisons Act by means of a medical man's prescription. The fact, then, that the public are able to obtain repeated supplies of poisonous drugs on the strength of a prescription shows an absence of discretion on the part of the chemist.

Crime Waves.

There has recently been an epidemic of attempted suicide by means of corrosive sublimate in America, and a contemporary blames the press for giving it publicity. It would be as rational to blame a medical review for the spread of typhoid. We do not, of course, doubt that a medical review might precipitate an attack, but only by making things easier for the bacillus. So with suicide. All that the papers did was to arm American Hamlets "against a sea of troubles and by corrosive end them," though to judge by their want of success with so toxic a drug they must have been the merest tyros in suicide. The Press does not incite to crime, though it may determine it, but surely that is not a sufficient reason for treating the public like an embryo criminal.

Atrocities.

A writer in a recent book on criminology defines war as "the highest and most absolute possible expression of crime which has become a mutual affair"; in the sense, perhaps, that it is a reputable or at least a time-honoured outlet for the collective brutality of a people. Events in the Balkans have once more shown that the cruelty of man is exalted when it becomes the cruelty of men. A multitude imbued to the pitch of action with an idea, say, of vengeance, will proceed like a river to attain its end along the lowest levels. The several members of a body of men are as if hypnotised by a corporate aim and tend to act impersonally, blind to the considerations that would restrain them as individuals. As their inhibitive faculties diminish they are left to the growing control of their emotions, and in the end the sword wields the man. A common focus of attention, even, may diminish individual judgment. It is notorious that a jury can be swayed by emotional insincerity on the part of counsel that would absolutely fail to impose on the jurors severally. That is the reason why it is notorious. In a word, men *en masse* are inhibited in their higher nerve centres, and the average man is often reduced to an average animal.

"Sore Labour's Bath."

Cleanliness is next to godliness, and it is right there in Philadelphia. A large firm has offered to give every man in its employment 15 cents every time he takes a bath. There are 700 employés and over two-thirds have accepted the offer. Baths are limited to one a day for each man, and must be taken when he is off duty. The company supplies towels, soap, showerbaths, and "nickel-plated equipment," whatever that may be. It is a great idea. Each of us knows too well the shop man who is continually "washing his hands with invisible soap in imperceptible water." If the idea is extended how happy he will be to think that all his practice has not gone for naught, but will enable him to earn his money in record time. If the British working man takes seriously to the daily bath, after we have recovered from the groundless panic about an insidious, symptomless epidemic of wasting disease, we will find many old notions upset. Not even treacle, let alone blood, will be thicker than the water that flows down the waste-pipes of our factories in the days when soaking is subsidised. While there's life there's soap, and if soft soap is translatable into hard cash the motto will be "pay and the world baths with you, don't and you steep alone."

Acta Virumque.

In this eugenic epoch the disciples of Mendel are fond of impressing upon us the utter unimportance of environment. Our surroundings and the life we live affect us very little: like manure to the pea, they touch us quantitatively but leave us essentially unchanged. Believing all this, as we must to uphold our reputation for modernity, we need no longer bother ourselves, if we ever have, about such questions as the coincidence of trade and type. We used to wonder which was cause and which effect: whether a calling affects a man's manner and appearance, or whether a certain class of man takes up a certain class of work. We all know trades that show types of countenance and conduct in the men that follow them. The stout omnivorous commercial with the "*Je ne sais pas* we call his touch and go." The ruddy butcher whose temporal hair strives to simulate the cornal protuberances of the beasts who die that he may live. And the police—by their boots shall ye know them. So on for columns. Even our own versatile profession has its typifers in the public eye. Two classes of doctor are generally recognised. They may be classed, with emphasis on the fact that the qualities are not mutually exclusive, as "respectable" and "clever." The former is held to be the real doctor, and should have a straggling moustache, a serious middle age and a sympathetic manner. The latter must shave clean and should collect prints or old china. It is a much easier degree to attain to than the other, but there is no need to say so to the man who reads this. He obviously is a combination of the best qualities of both types, and not to be classed with either, but is pedestalled in triumph on a fane of righteousness.

"Examen."

Our system of education affords a great opening for cranks, who are usually people who cannot teach, and therefore can tell others how to do so. For some years examinations of assorted kinds have been the ultimate test, and knowledge which passeth all examinations is of more practical value than a real ability to do. It seems time for us to get rid of this over-systematised method, but it is very hard to replace it by something better. We read, mark, learn, and suffer from internal dyspepsia due to the loads of learned lumber that we cannot assimilate. The most useful quality an educated man can have is a selective forgetfulness. Conventional learning cramps us, but it gives us a ground of common assumption in our relations with each other, and our real education is acquired in our spare time. A glance at the real meaning of "examino" gives us rather a shock. Primarily it means "to form swarms," and is used exclusively of bees, locusts and children loosed from school. The unconscious satire of the lesser Smith epitomises perfectly the pedantic principles of our peerless pedagogues.

The Butter of our Grandfathers.

There can be no doubt of the value of butter as an article of diet. It is blessed alike by vegetarians, fruitarians, and mixtarians (to coin a word) alike. What soul so fastidious or what stomach so pampered as to withstand the attractions of a fine, wholesome, primrose-yellow English country butter? That was so in the days of our youth, but, alas, the butter of to-day for the most part comes no more from English dairies, but hails from distant countries, and is blended with milk and with other mysterious compounds that destroy the flavour and character of the product prized by our grandfathers. The process of blending breaks up the fat molecules, so that the butter no longer cuts cleanly, but clings obstinately to the blade of the knife and clings greasily to the crockery. The cheaper so-called butters are as a rule permeated with mould fungus and have no pretension to the real distinctive butter flavour. Yet good, old-fashioned country butter can command a higher price than ever it did, if there were only some way of bringing it from farmer to customer without the intervention of the middleman, who has well-nigh succeeded in destroying our native cheese and butter industry.

The Prevention of Trypanosome Infection in Africa.

The question as to whether the destruction of game in certain parts of Africa would lead to a diminution in the amount of trypanosome diseases of animals and man is one which has been uppermost in the minds of many experts in tropical disease owing to recent researches. It is satisfactory to note, therefore, that the Secretary of State for the Colonies has nominated a Committee to report: (1) Upon the present knowledge available on the questions of the parts played by wild animals and tsetse flies in Africa in the maintenance and spread of trypanosome infections of man and stock; (2) Whether it is necessary and feasible to carry out an experiment of game destruction in a localised area in order to gain further knowledge on these questions, and, if so, to decide the locality, probable cost, and other details of such an experiment, and to provide a scheme for its conduct; (3) whether it is advisable to attempt the extermination of wild animals, either generally or locally, with a view of checking the trypanosome diseases of man and stock; and (4) whether any other measures should be taken in order to obtain means of controlling these diseases. The Committee will be composed as follows: The Right Hon. the Earl of Desart, K.C.B. (Chairman); Mr. E. E. Austen, British Museum (Natural History); Dr. A. G. Bagshawe, Director of the Tropical Diseases Bureau; Dr. Andrew Balfour, C.M.G., late Director of the Wellcome Research Laboratories, Gordon College, Khartum; Sir John Rose Bradford, K.C.M.G., Secretary of the Royal Society; Mr. E. North Buxton, Chairmon of Quarter Sessions, Essex; Dr. W. A. Chapple, M.P.; Sir Mackenzie D. Chalmers, K.C.B., C.S.I.; Lieutenant-Colonel Sir W. B. Leishman, F.R.S., Professor of Pathology, Royal Army Medical College; Sir Edmund G. Loder, Bart., Vice-President of the Zoological Society; Dr. C. J. Martin, F.R.S., Director of the Lister Institute of Preventive Medicine; Mr. J. Duncan Miller, M.P.; Dr. P. Chalmers Mitchell, F.R.S., Secretary of the Zoological Society; Professor R. Newstead, F.R.S., Liverpool University; Mr. H. J. Read, C.M.G., Colonial Office; The Hon. L. Walter Rothschild, F.R.S.; and Sir Stewart Stockman, Chief Veterinary Officer, Board of Agriculture and Fisheries. Mr. A. C. C. Parkinson, of the Colonial Office, will act as Secretary.

PERSONAL.

The Duchess of Albany visited the Cobham Cottage Hospital on the 30th ult. and opened a new ward and operating theatre, erected at the cost of about £12,000.

Mr. W. McAdam Eccles, M.S.Lond., F.R.C.S., has been appointed Surgeon to the London Temperance Hospital.

Dr. Farquhar Macrae has been appointed Tuberculosis Medical Officer for Aberdeenshire.

Mr. Arthur H. Evans, M.S., F.R.C.S., has been appointed Surgeon to the London Temperance Hospital.

Dr. G. S. Glass, M.B., D.P.H., has been appointed Assistant Medical Officer of Health for the Borough of Southampton.

Mr. James Mclure, F.R.C.S.Eng., has been appointed Surgeon to Outpatients at the London Temperance Hospital.

Dr. John Scott Haldane, M.D., F.R.S., has been awarded the Baly Medal of the Royal College of Physicians of London.

Mr. John Stroud Hosford, F.R.C.S.Edin., has been appointed Ophthalmic Surgeon to the London Temperance Hospital.

Dr. Allan Hastings Hanley, C.M.G., F.R.C.S.I., has been appointed Resident Medical Superintendent of the Peamount Sanatorium.

Dr. Charles Hewitt Miller, M.D.Cantab., M.R.C.P.Lond., has been appointed Assistant Physician to the London Hospital.

Mr. J. Gay French, M.S.Lond., F.R.C.S., has been appointed Surgeon-in-Charge of the Throat, Nose and Ear Department at the Royal Free Hospital.

Dr. John Guy, Tuberculosis Medical Officer for the County of Gloucestershire, has been appointed to a similar post by the Edinburgh Town Council.

Dr. C. J. Campbell Faill, M.R.C.P.Edin., L.R.C.S.Edin., has been appointed Tuberculosis Medical Officer for the City and County of Bristol.

The title of Assistant Professor of Hygiene and Public Health at King's College, London (University of London) has been conferred upon Dr. David Sommerville.

The entrance science scholarships at St. Thomas's Hospital Medical and Surgical College have been awarded to W. E. Le Gros Clark, £150, and S. A. T. Wade, £60.

Dr. Malcolm Donaldson, M.B., B.C.Cantab., has been appointed Demonstrator of Midwifery in the Medical School of St. Bartholomew's Hospital, dating from October, 1913.

Mr. S. H. Warren, M.R.C.S., L.R.C.P., D.P.H., Demonstrator of Bacteriology at the University College Hospital Medical School, has been appointed Graham Scholar in Pathology for the sessions 1913-14 and 1914-15.

Mr. A. Rendle Short, F.R.C.S., Assistant Surgeon to the Bristol Royal Infirmary, has been elected a member of the Board of Examiners in Anatomy and Physiology for the Fellowship of the Royal College of Surgeons of England.

The announcement of the retirement of Dr. Francis Warner from the active medical staff of the London Hospital will be received with widespread regret by "London" men, past and present. That institution will, however, retain his services as Medical Examiner of nursing candidates.

The Charles Murchison Scholarship, instituted in 1880, to perpetuate the memory of Dr. Murchison, and awarded alternately by the University of Edinburgh and the Royal College of Physicians of London, has been awarded by the University to Alan W. S. Sichel, B.A., M.B., Ch.B.

On Wednesday evening last a large number of Veterinary Surgeons from all parts of the Kingdom entertained Sir John McFadyean, M.R.C.V.S., M.B., B.Sc., at a dinner held at the Trocadero Restaurant. Sir John is a member of the Royal Commission on Tuberculosis, and Principal of the Royal Veterinary College.

Fleet-Surgeon O. W. Andrews, in charge of the Medical Department of Devonport Dockyard since August 17th last, who retired the other day from the Navy with the rank of Deputy Surgeon-General, has left Devonport to take over the appointment of Medical Officer of the Forest of Dean, under the Gloucester County Council.

The Raymond Horton-Smith Prize for 1913 in the University of Cambridge has been awarded to Dr. F. A. Roper (Trinity) and Dr. F. S. Scales (Jesus), who were adjudged equal for their theses for the degree of M.D. on the following subjects respectively: —"Creatinine and Creatin Metabolism, especially in reference to Diabetes," and "The Electrocardiogram as an Aid to Diagnosis."

An interesting ceremony took place last week at the Royal Society of Medicine, when Sir Thomas B. Crosby, M.D., last year's Lord Mayor of London, was presented with a service of silver plate and a book containing the signatures of about 300 medical men who had subscribed thereto. The presentation was made by Sir Rickman Godlee and Mr. Bramley Taylor, and Sir Thomas Barlow was in the chair.

Mr. James Henry Targett, M.B., M.S., F.R.C.S., of 19 Upper Wimpole Street, W., obstetric surgeon and lecturer at Guy's Hospital, and senior examiner in midwifery to the Conjoint Examining Board, who died on May 27th, aged 51, left estate of the gross value of £35,722, of which the net personalty has been sworn at £35,474. He left his shares in the Clinical Research Association (Limited) to the treasurer of Guy's Hospital, for the benefit of the pathological department of the medical school of that hospital.

CLINICAL LECTURE

ON

DIAGNOSIS IN RESPECT OF CERTAIN SYMPTOMS AND SIGNS IN CHILDREN. (*a*)

By SHEFFIELD NEAVE, B.A.Oxon., M.R.C.P.Lond.,

Physician to the Queen's Hospital for Children.

MENINGISMUS.

THE complex of signs and symptoms which have been well named meningismus owing to their similitude to meningitis itself is much commoner in children than in adults. At the commencement diagnosis between the two is often difficult.

The word meningismus is not to be found in older text books. It was noticed that many cases of disease were accompanied by some of the signs of approaching meningitis, but that these passed away, and one was left with a frank case of some ordinary ailment. This word was therefore coined for this state of things, and it would appear that though there is irritation of the same structures in both cases, yet the cause is of different nature.

One must not include as meningismus any affection of the meninges or cortex that can be recognised *post mortem*. In typhoid fever and pneumococcic attacks, for instance, both a definite attack on these membranes may be made by the bacillus itself, the gross effects of which are recognisable *post mortem*, and in other cases an imitating meningismus may occur early in the same disease. We may distinguish between the two pathologically by saying that the meningismus is due to the toxin of the causative micro-organism, while meningitis itself is due to the migration of the micro-organism itself into the meningeal tissues.

On the other hand, one is perhaps apt to use the word toxin a little too glibly without really being able to prove its existence, but it seems the best explanation for the moment. It is possible in this way that meningitis may be preceded by meningismus, that is to say that the intra-cranial attack may be commenced by the toxins of the micro-organism before its actual arrival on the spot, some even go so far as to say meningismus is only an abortive attack of meningitis. On the other hand, some of the attacks of meningismus do not appear to be traceable to an organism.

Many signs are common to the two affections, but the following are practically never present in meningismus :—

1. A bulging anterior fontanelle.
2. Optic neuritis.
3. Grouped breathing.
4. Abnormal cerebrospinal fluid.

(Some qualification should be made perhaps as to the last point, as Horder states that a slight increase of albumen and lymphocytes has been found.)

Besides a differential diagnosis from meningitis we have also to determine the disease which causes the meningismus.

As we have seen above, before an acute disease declares itself there are often a number of signs that are termed prodromal, and among those connected with the nervous system are those of meningismus, which may closely simulate the onset of meningitis, instead of really being precursors to a quite different disease.

In addition to acute diseases there are also a number of more chronic pathological states in which marked nervous symptoms may flare up into the same picture of cranial irritation :—

(A).—Pneumonia, typhoid fever, entero-gastritis, form examples of acute attacks not usually accompanied by meningismus.

(B).—Constipation, difficult dentition, otitis media, are some of the more chronic ailments which may have the same affection in their course.

A.—In the first set of instances it may be some days before a correct diagnosis is made between the two ailments, and not unfrequently these cases are sent into hospital as meningitis, which at this stage is often really the more probable diagnosis.

(1) The commencing signs of pneumonia are proverbially protean, and they include the syndrome to which the name of meningismus has been given. In children the disturbance of the nervous system is less in this disease than in adults, but, nevertheless, one sees a good many marked cases of it. One has seen pain in the abdomen with concomitant signs lead to a diagnosis of peritonitis or some cognate inflammation only for it all to rapidly disappear and to be followed in its turn, perhaps, by signs of meningismus. Headache, vomit, delirium, retraction, photophobia, squint, a desire not to be disturbed, with intervals of semi-conscious and cephalic cry, may all be present, but pass off in their turn as the lung signs become more marked. They may continue for some days, though on the other hand they may not last many hours. After this display of so many signs and symptoms the practitioner is then left with an ordinary case of pneumonia with which to deal. It must be remembered, too, in children that the chest signs of consolidation may appear quite late in the disease, even close on the crisis.

There is a connection between apical pneumonia and nervous symptoms which is not well understood, thus in adults heavy drinkers and cases of D.T. are peculiarly liable to this form. In the same way in children if meningismus occur as a prodromal of pneumonia it is probably apical. In pneumonia the number of apical cases, too, are greater in children than in adults, being about one-third of the whole. The rate of respiration is of great assistance in diagnosis from meningitis, and the temperature will give some clue ; thus in basal meningitis the rate of breathing is not often increased, and if there is a high temperature it is usually accompanied by complete remissions, while in the tubercular variety the breathing is also not rapid and the temperature is not often above 101°. On the other hand, herpes is common in both meningitis and pneumonia.

(2) Meningismus in typhoid fever may similarly occur as a prodromal sign, and here we do not have the rise in the rate of respiration nor so marked a rise in the temperature to help us. Typhoid fever is in any case often hard to diagnose in children, so that diagnosis as to these prodromal nervous symptoms perhaps presents the greatest difficulties in this instance, and a "wait and see" policy will often have to be adopted, with a revision of the whole case at every visit. We have already said that true meningitis may occur as well in the course of the disease.

(3) The meningismus which accompanies *entero-gastritis* (but more especially the form of *summer-diarrhœa*) and *cyclic-vomiting* may often be distinguished from meningitis by the depressed fontanelle, in contradistinction to the fontanelle in that disease, which is tense and raised by the internal pressure of the cerebrospinal fluid. It must, however, be remembered that if a large quantity of this fluid be removed, pressure being thus reduced the fontanelle may be no longer affected. This obtains in cases where men-

---

(*a*) Lecture to Post-graduates delivered Tuesday, May 3rd, 1913.

ingitis has been treated by continuous drainage of the cerebrospinal fluid, and the fontanelle is thus depressed instead of raised.

In all these cases an early lumbar puncture is very advisable in view of diagnosis; nowadays this little operation may be considered quite safe if the ordinary precautions are carried out with care. It may even be of some use as treatment by reducing the intrathecal pressure. In meningismus, as we have seen, the cerebrospinal fluid is normal, so that if this is found to be the case a favourable diagnosis is more likely to be correct, though another specimen should be examined later if the symptoms persist. In this way the naked eye observations that the fluid is turbid or not before any report is made by a pathologist may be of great value.

B.—In the second group of the more chronic ailments in which meningismus may appear we may take the following:—

(1) *Constipation* is both the accompaniment and the cause of so many other ailments that it is useful always to hesitate to give any diagnosis where it exists until the bowel has been emptied, unless there is something undoubted to go by. This rule is more than ever useful in the meningismus caused by it, as constipation is also a common sign of true meningitis, and one is often led to expect this, when really an aperient will set matters right in a few hours.

(2) *Difficult dentition* presents us with another instance, and in respect of this there has been much discussion as to how many of the signs and symptoms that occur during the process should be put down to it, or whether they are not due to some coincident malady.

Dentition is certainly the cause of some symptoms on its own account, but rickets, for instance, if concurrent will cause a temperature and aggravate the swelling of the gums. Yet there is a residue of cases, however small in number, where there is nothing but dentition itself to account for *twitchings*, *convulsions*, *squint*, and *retraction* of the head preceded by irritable *restlessness*. A point in diagnosis which, however, may help us are the violent *screaming fits* which may occur. These appear to be of *nervous origin* rather than to be caused by any pain that may be present, and sometimes may be of an almost maniacal character. These cries differ in intensity from the cephalic cry of meningitis, although of cephalic origin. All such symptoms in any cases are naturally more likely to occur in specially nervous children, and the crying is usually at night for some reason.

(3) *Otitis media* may accompany difficult dentition, and has been thought by some to be an extension of inflammation from the gums, at any rate it is an affection that may well account for either meningismus or meningitis.

Wasting.

The physician meets this sign every day in practice connected with the ailments of children, in fact, on being consulted, one of the preliminary thoughts that enter his mind should be how well or how badly the child appears to be nourished.

The cause of wasting is sometimes difficult to ascertain and it may only be possible to arrive at a diagnosis after the results of treatment are known, and several remarks will be made here in respect of treatment on this account.

From the point of view of ætiology this subject may be divided into:—

1. Marasmus.
2. Wasting having a direct cause.
3. Wasting as a secondary sign of some disease.

1. *Marasmus.*—This disease, from a clinical point of view, may be defined as wasting where examination in life and *post mortem* yields only the same signs as in cases of starvation, and where any complication that exists might equally occur in starvation. Digestion appears to proceed, and the stools may be natural, but the child wastes and the weight becomes less and less, and as exhaustion increases sudden death often supervenes, treatment having completely failed.

It is obvious that these cases of inability to assimilate must be found in early infancy, as this incapacity of a particular type of cells is, in the absence of actual disease, much more likely to be developmental and congenital than acquired. Theoretically absence of assimilation may be due to the failure of the secreting and excreting cells of the digestive organs, or to the inability of the general tissue cells to absorb their productions, but the latter is unlikely seeing that these cells must have already had this power of absorbing nutriment from the maternal blood in utero.

It is common to find that a case of marasmus is in a baby coming at the end of a long series of confinements with exhaustion of the mother

The inability to assimilate may not be complete, and it is on the chance of this that treatment may be undertaken with some hope of success.

In the diagnosis of marasmus one must of course start by endeavouring to exclude disease and other causes of wasting. These are numerous and will be dealt with later, but no effort should be spared not to treat a case as marasmus which has an ascertainable cause. One has to start by endeavouring to ascertain whether the child or the food, or both, are at fault, or, again, whether there is disease.

It has often been observed that our knowledge in respect of the internal secretions of many organs is highly deficient, and it has been thought that as some of them certainly influence development, some of these secretions and their resulting hormones may be at fault in marasmus, but the administration of thyroid, pituitary and adrenal extracts have not met with much success, and very little more so far is to be said for pancreatic extract, secretin and other bowel extracts, which have been suggested. The idea, however, opens up a wide field for investigation.

2. *Wasting having a direct cause.*—This subject may be divided under the following heads:—

(1) Absence of food or its obstruction on its way to the assimilating organs.

(2) Deficient or improper food.

(3) Defective action of organs connected with the preparation, assimilation or storage of food.

(4) Cachectic states due to evil surroundings or habits;

1. As instances of absence of food and its obstruction the following will suffice

The teat of the breast or the teat of the bottle, due to shape or deficient aperture, may be at fault, the milk not passing, or the bottle may be so arranged that no air entry prevents the exit of the milk.

The sucking power may be deficient, or the milk may not pass beyond the mouth and pharynx because the sucking or swallowing powers are faulty. Harelip split palate, obstructed nose, obstructed larynx, are examples of this difficulty. Pyloric obstruction complete or partial, causes the return of the food from the stomach.

The child may refuse to take the food owing to some evil flavour or discomfort in the manner of feeding.

Diagnosis being made in these cases, the treatment aims at allowing the mechanical passage of the food

2. Deficient or improper food

(a) The breast may not secrete sufficient milk. To ascertain this the baby should be weighed before and after (*a*) sucking. Some of the constituents may be deficient, hence an examination of it must be made to ascertain the percentages of them.

(b) Some drug that is deleterious to the infant may be excreted with it. The drugs that may be excreted with the milk include saline aperients, salicilates, quinine and arsenic, as well as the haloids and mercury. The two drugs among these that would probably give the milk a marked flavour are quinine and potassium iodide.

The contents of the bottle may be deficient in amount or of wrong dilution or constitution. It may be here said that the underlying principle in the matter of dilution should be to see how strong of milk the mixture should be for each particular infant; thus we must

---

(*a*) Particulars of this process were published by Dr. Er Pritchard, *Lancet*, September 2nd, 1911.

experiment with each case to see how little water need be added, and not treat all babies in accordance with a list of dilutions out of some book as if they were all made in the same mould.

3. Organs connected with the preparation and assimilation or storage of food may be defective in function or constitution, thus the gastric secretions may be deficient or in excess, and the liver may not be secreting bile in proper quantity or quality, or some obstruction to its passage to the intestines may exist. The pancreas may be at fault, as is proved in some cases by success obtained occasionally through the administration of liq. pancreaticus. Chronic constipation, tape and other worms, may also be mentioned here, likewise the question of bad teeth, and inferior mastication among older children must not be forgotten.

The main difficulty, however, is manifested by symptoms of indigestion, such as vomit, diarrhœa, constipation and screaming, and to overcome wasting under these circumstances is a task involving much work and difficulty in many instances. Drugs may be of value, but the fault may be inherent in the feeding.

In the feeding of infants on the bottle two important theories run through the principles of treatment. Firstly, that the constituents of the milk should be approximated to human milk; secondly, that this having failed it is only one of the constituents that the child cannot digest and that this must be reduced.

To avoid the trouble that the above involves the peptonising of the milk is often a short cut to success, but when this fails the incapacity to deal with the three main constituents of milk may each be suspected, and these in turn as constituting the difficulty, may be reduced to a minimum in the diet administered. I mean, of course, proteids, fats, and carbohydrates, *i.e.*, casein, cream and sugar, and it is best to take them in this order when commencing to experiment with the food. It is usual in England to look upon proteids as being most often the difficulty in the digestion of children, but in Germany the fat is often considered the greatest delinquent. Among the lower classes too much sugar, and in the upper, too much cream is ordinarily given, so that these mistakes should be corrected before going further. The methods of making these reductions have been discussed *ad nauseam*, and may be found in any text book on children, but a few words may not be out of place here, as some habitual plan of action is of value in thinking out the pros and cons of a case.

Whey contains the sugar, the lactalbumen, the salts, and 1 per cent. of the fat, so that it makes a good foundation for the making of proportionate mixtures, as the casein, and most of the fat has been got rid of, and there is less sugar in cow's than human milk. In fact, each constituent is present but in less proportion than in human milk.

If more proteid is desired albulactin can be added, if more fat cream can be added and the sugar can also be made up. To increase the proteid lactalbumen is suggested, as the proteid in human milk is lactalbumen with very little casein.

A very diluted milk is not unfrequently useful, but this, of course, merely reduces all the constituents *en bloc*, both those that are well digested and those that are not. To this, of course, more of each constituent can be added as required, and this process is simpler for poor surroundings.

The amount at each feed will also have to be considered, and the frequency of feeding, as well as the question of giving raw milk as against boiling or heating it. The gain in weight does not seem to be in proportion to the amount of milk apparently digested, and in some cases when a baby is not thriving although taking a largish quantity it may be advisable to try some reduction.

In addition to those cases which respond to the modification of the proportions of the milk constituents, there are instances of success attending that which is more purely empirical and artificial treatment, thus preserved milk of the sweetened variety diluted one to three parts water contains about the same proportion of milk constituents as whey. Dried milk may also be tried. Sodium citrate one to two grains to the ounce of milk is supposed to diminish the size of the curd of cow's milk, and in some cases permits of this being taken without dilution. It may, however, aggravate œdema and purpura, which are well-known complications of extreme wasting. Its action in some cases may be connected with its action on acids produced by the excess of sugar which mothers are apt to insert in the bottle.

As a more rare instance of success attending an empirical treatment, it is generally held that starch is incapable of digestion before seven months, and yet there are exceptions recorded, however rare, where it seems to act satisfactorily, and it is stated that the Chinese successfully rear their infants on rice water. On the same principle malted milk has had its successes, and it has been recommended to boil arrowroot with veal broth in place of the usual albumen water as an interim diet before returning to milk where this has been temporarily contra-indicated.

A word of warning should be entered here against a constant change of an infant's diet, as it not unfrequently happens that by persevering with one diet the digestive organs seem to accommodate themselves to it, while a sudden change in a bad case may appear to bring about a fatal result. When a weak wasted infant is brought to you, you are usually confronted with the serious fact that you have only a certain number of days of life in the infant left in which to hit off the life-saving diet if such exists at all, so that there is a temptation to make changes of diet too soon and too frequently.

This indigestion and wasting may occur both with the breast-fed and bottle-fed infants. The breast milk in the former case cannot well be modified, though a good deal can be done by attention to the diet of the mother, and by use of the bottle in substitution or addition to the breast milk.

There is a point here which, though not new, has been enlarged by further knowledge lately. I refer to what is called the biological value of milk. For instance, why should a wet nurse from the country be better than one from the town? Why should fowls suffer from polyneuritis and Chinamen from beri-beri, when a minute particle of pyramidine be removed from a rice diet by polishing the grain, and be cured by administering it to them again? Why should heating all food up to 120° C.C. cause scurvy,—and retard growth? (*a*)

Again, cows can be so fed with artificial food that their milk produces gastric disturbances in children; under these circumstances it is necessary that the food of the mother during lactation should be carefully looked to, so that it should not be too much of an artificial nature.

(4) Under the head of general cachectic states due to condition and evil surroundings or habits, come a number of cases commonly met with. *Poverty*, *prematurity*, *ill-development*, are not so hard to diagnose, while *exposure to weather*, *confinement to the house in bad air*, *want of sleep*, and *over fatigue* may be more difficult to discover, although they may be equally causes of wasting. *Masturbation* should also not be forgotten.

3. *Wasting as a secondary sign of some disease.*—We need not dwell on the wasting that occurs in the course of any long illness, but we may take the following as the more prominent instances in which we may get some cases where wasting is the only sign to be discovered on a clinical examination, though usually it occurs only as a secondary sign :—

(1) Syphilis.
(2) Tuberculosis.
(3) Congenital heart disease.
(4) Empyema.

Of these diseases which usually cause wasting as a secondary sign, syphilis and tuberculosis stand out

---

(*a*) Crookshank, *Jl. Children Diseases*, November, 1912.

pre-eminently. The former claims more cases in infancy, the latter in childhood.

(1) *Syphilis.*—There seems no doubt that syphilis can exist with the only symptom of wasting, and in the past the exhibition of mercury has often been the only practical way of shewing this. It frequently happens that the mother's history of herself, her confinements and her children reveals nothing, and yet that congenital syphilis exists in the child brought to you. The Wassermann test has now, however, considerably reduced the difficulty. Of course, wasting is not usually the only sign met with, but these cases exist. The facies, the skin, snuffles, condylomata, enlargement of the spleen and other viscera, as well as much long hair in infants, and peculiarities of the teeth in older children are all things to be carefully looked for as corroborative signs.

(2) *Tuberculosis.*—Tuberculosis in children is a common cause of wasting. Of course, when its existence is obvious causation presents no difficulty to the practitioner, but it sometimes occurs in such a way as to be a great puzzle. Thus a dissemination of small tubercular points in the lungs, pleura and peritoneum may exist without any signs, and although a diagnosis of tubercle may eventually be made, a long wasting and cachectic period may persist before it is so determined. Where this miliary tubercle is suspected the eyes should always be examined, as the choroid is more often affected than has been generally supposed. The younger the child the quicker the dissemination, as in infants tuberculosis is much more of a blood disease, but after two years the above period of doubt may be considerable.

Under these circumstances where there is wasting we must always be on our guard against giving a negative opinion without much careful observation. A positive Von Pirquet reaction in such a case does not tell us much, especially if in an older child, but if negative after two applications it would be evidence against the disease existing. A more reliable method would, of course, be the injection of old tuberculin. Phthisis is regarded as being rare in childhood, so that we do not have its signs to assist us very often. At the same time it is not so rare as is generally stated, and I have three cases, 4, 6 and 8 years old, in the wards now under my care that I can show you presently. (*a*)

In a case of distended abdomen with wasting it is often hard to decide whether you have a case of tuberculosis or not unless the characteristic doughy feeling and the usual transverse bands or fluid are present; some assistance is often got by examining under an anæsthetic.

(3) *Congenital heart disease.*—Another disease which may have wasting as the most prominent sign is congenital heart disease, and if as often occurs there is no cyanosis or other such obvious sign it is apt to be overlooked, so that an abnormal condition revealed by the stethoscope and percussion may often be the key to a case of this sort. Babies with this disease may be hard to examine owing to much crying and the examination of the chest may be necessarily incomplete, but if a certainty cannot be arrived at at one examination, it should not be forgotten at the next. This defect in circulation makes the child more than usually liable to many disorders, and want of assimilation is often one of them, so that some of the best specimens of this defect arrive at the hospital for the treatment of wasting.

(4) *Empyema.*—Cases of wasting in this disease are usually where the child has had some lung attack, and has been ill ever since with an empyema that has not been discovered. It is a condition that is often difficult to prove, and hence should be carefully borne in mind.

Wasting Confounded with Nonpathological Thinness.

While searching for the causes of wasting, there are on the other hand cases where a child is abnormally thin or short of muscle (often being born of similar parents) without any pathological symptom or sign, and when he appears to be in perfect health and capable of as much as his stouter brethren. Similarly we get shortness of stature, which, however, may be pathological, as a case is given where a lad of sixteen who was too short for the Woolwich standard was induced to grow six inches in six months by the exhibition of thyroid extract.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Professor E. Kermisson, M.D., Professor at the Faculty of Medicine at Paris. Subject: "Osteomyelitis in Infants."*

ORIGINAL PAPERS.

THE GIFTS OF SURGERY TO MEDICINE. (*a*)

By SIR BERKELEY MOYNIHAN, M.S., F.R.C.S.,

Professor of Clinical Surgery in the University of Leeds; Surgeon to the Leeds General Infirmary.

By a study of what I have ventured to call the "pathology of the living" a very profound change has by degrees crept over our knowledge of almost every form of chronic abdominal disorder.

In the earlier years of the nineteenth century an acquaintance with the morbid processes attacking internal organs was based upon two sources of information only—upon an inquiry into the details of the clinical history of any disease as it developed, waned, or progressed, and upon the examination of the parts involved after the death of the sufferer.

I have endeavoured to show, on more than one occasion, how impossible it is to measure the sufferings of patients during their lives, or to assess their chances of death from any disease, by a consideration of the statistics gathered from the *post-mortem* room experience. People do not die in hospital from the chronic diseases from which they suffer during life. It is, so far as the surgical side is concerned, the acute terminal infections, malignant disease in all its forms, especially those lending themselves to surgical consideration, and the accidents of civil life, that supply the bulk of the material upon which the pathologist makes his observations.

When the great gift of America to humanity—the discovery of the anæsthetic power of ether—was brought to the aid of the operator, vast possibilities were at once apparent in the range of the surgeon's work. But the dread of infection—indeed, the certainty of infection—held his hand for more than a generation, till the work of the greatest man our profession has ever produced, Lister, made the dream of the surgeon come true, made it possible for him with safety to carry through many procedures which before had been impossible.

The Appendix the Scapegoat.

As we began to recognise, almost unconsciously, the ease and sufficiency of the simple mode, the mortality from all operations fell rapidly. So it became a safe and customary procedure, not only to deal with the particular lesion which had demanded attention, but also to investigate the conditions of adjacent organs. And there surprising developments awaited the inquirer and rewarded his eager search. Conditions other than those which needed immediate attention were found to exist with no little frequency. In

(*a*) Abstract of the Address in Surgery delivered at the 81st Annual Meeting of the British Medical Association, held at Brighton, July, 1913.

diseases of the stomach or duodenum, the gall bladder was found not seldom implicated also; in diseases of the latter, as of the former, the vermiform appendix seemed often to play the part of an infecting agent. And so by slow degrees the conviction was borne in upon us that these diseases I have named did not stand in rigid isolation, one separate entirely from the other, but that their association was so frequent as to indicate the strong probability of some underlying primary cause. Infection, it was soon asserted, whether carried by the the blood stream, by the lymphatics, or ascending, as Bond has shown with great clearness, along the mucous canals, was the prime evil. Differences of opinion were soon declared, and still continue, as to the source of the infection. To many of us the quiescent inflammatory lesions of the appendix seem the most potent and the most persistent of all. Arbuthnot Lane, as I shall presently state more fully, holds firmly to the belief that the infections for the diseases I have named, as of many others, have their origin in the intestine, large or small.

The Reduction of Shock.

The perfect surgeon must have the "heart of a lion and the hand of a lady"; never the claws of a lion and the heart of a sheep. During any surgical operation, Crile assures us, there is, in reply to every incision, every pull of the retractors, indeed to every physical contact, a change in the pulse, the respiration, and the blood pressure. Every surgeon conversant with abdominal work knows how a rough handling will cause tension in the muscles and deepen the patient's breathing, making loud and stridulous the expiratory effort, as though the victim were groaning in his agony. No general anæsthetic, it is clear, can shelter the brain from the assault committed upon it by the injuries inflicted during an operation. Crile has therefore suggested that by means of local anæsthetics—novocaine for the skin, quinine and urea for the parietal peritoneum—a barrier can be erected around the area to be operated upon, so that no nerve impulses can be conveyed from the territory so isolated. The field of operation, that is to say, may be temporarily disconnected from the brain, not only at the time of operation, but for periods of one to five days subsequently. Shock may be produced not only by physical violence, but also by psychical disturbances, by emotional excitement, by the receipt, for example, of good or bad news or by fear, the suspense and the trials of some great ordeal. By many patients their submission to an operation is viewed with dread and apprehension. In order that the best results should follow upon our work it is necessary that every consideration should be shown to a patient, and every proper regard to his wishes; every encouragement should be offered, and the impression forced upon him that all those engaged in the operation or his after-treatment are working strenuously to the one end—his assured and rapid recovery. The fears which hover round the last hour before an operation are greatly modified by the administration of a small dose of morphine with scopolamine. A happy frame of mind is thereby induced, and very little nitrous oxide gas is required to put the patient soundly to sleep. The memory of the conveyance of the patient to the operation theatre and of the administration of the anæsthetic is often abolished by these measures. This is, in brief, the method of Crile, which I have used for many months, and which has added a pleasure to my work that is really immeasurable. To the great discoveries of Morton and of Lister this of Crile seems to be the fitting completion.

The Source of Gastric Ulceration.

There is now no longer any doubt in my own mind that the commonest site of a "gastric ulcer" is in the right iliac fossa. That is to say, that in the majority of cases in which the most erudite teaching of the most astute German physicians would justify or compel a diagnosis of ulcer, the patient is suffering from a lesion elsewhere, and more often than not from a lesion in the appendix. The appendix may present a variety of conditions, but they are all alike in one particular—they are all obstructive in character. Infection and obstruction together, or apart, as Sir Bertrand Dawson has well said, make all the ills from which a patient derives abdominal trouble. In the appendix both may be at work at the same moment, indeed, one follows inevitably upon the other. In my experience there is no appendicitis without obstruction. The present position of our opinion is accordingly this, that in many of the cases of "gastric ulcer," the symptoms of which are pain, flatulence, acidity, heartburn, vomiting, and hæmatemesis, the lesion primarily responsible for such symptoms does not lie in the stomach. The lesion is one in which infection and obstruction are in league to do harm, and its most frequent location is in the appendix.

The evidence seems to be increasing, and is, indeed, already abundant, in favour of the view that these distant infections, whether in the appendix or elsewhere, which often produce the gross lesions just described in the stomach may be the precursors and the excitants of a chronic ulcer of the stomach. Gastric ulcer, then, would appear to be almost always a secondary disorder; the primary fault lies not in the stomach, but elsewhere, its expression is manifest in the stomach because of the particular series of incidents which occur therein. This much is certain—that when cases of gastric ulcer come to the operation table the evidence of other and apparently older lesions is rarely wanting. Among the most notable of the gifts of surgery to medicine is the proof that in a large proportion of cases the onset of cancer of the stomach is not a new and unaccountable thing, but is, on the contrary, a tardy development upon an earlier condition which for years had clamoured for recognition. It appears to me that the work of the Mayo Clinic has offered irrefragable proof of this assertion. I am, of course, well aware that all cases of cancer of the stomach, unhappily, do not come to the surgeon. No one but the surgeon can do any good to patients so afflicted. Yet there is a strange timidity of approach to the surgeon which is unaccountable, and far too often the favourable period in the history of a case is allowed to slip away before any recognition of the real conditions is attempted. The infection, which has its origin in the appendix or in the intestine, wreaks other harm than that upon the stomach wall. Of duodenal ulcer and of cholelithiasis we have also learnt that they are usually secondary manifestations. Of duodenal ulcer I have so recently and so fully written that it is not necessary here to do more than record the fact that a full knowledge of its symptoms and course, and the power, unrivalled in any other abdominal disorders, of making an accurate diagnosis are not the least important of the gifts of surgery to medicine.

Cholelithiasis and Lesions of the Pancreas.

Every gall stone, as I have said before, is a tombstone erected to the evil memory of the germs that lie dead within it. The frequency with which gall stones lie inert within the gall bladder, causing no harm and arousing no symptoms, is so very small as to be quite negligible. It is certainly much less than 1 per cent. in all those cases which come for surgical treatment, and, though I admit that this estimate involves a possible fallacy, yet the truth cannot be known of all the cases in which gall stones exist, for neither operative work, nor the examinations of the dead, nor the records of the "spas" reveal the whole matter. The error that has found a place in the minds of all medical men, and has been faithfully carried down from one generation of textbooks to another—that in the majority of cases gall stones cause no symptoms—has been for ever dispelled by the work of the surgeon. In operating upon cases of advanced cholelithiasis a history of inveterate though perhaps trivial dyspepsia over a long period can almost always be obtained. In operating upon patients for the relief of other conditions—myoma of the uterus, ovarian or other pelvic conditions, appendicitis or ulcer in the stomach or duodenum—a routine examination of the gall bladder and kidneys should be made. Every now and again stones will be found in the gall bladder, and far more rarely in the kidneys. In the case of the former a clear history of dyspeptic troubles can, in my experience invariably, be obtained. It is true that these symptoms are not those which are commonly recognised as being due to a gall-bladder condition, but the gift of surgery to medicine consists here in the true portrayal of those clinical manifestations which only an examination of the living could disclose. We now know that the earliest symptoms, the "inaugural symptoms," of cholelithiasis are just as characteristic, just as certainly to be recognised, as those of the later sequels and avoidable complications. And more than this: the very little that was known of cholelithiasis in its clinical aspects has undergone a complete revision, with the result that we are often able to declare not only the presence of stones, but often the position of that which is causing the most serious trouble.

It is as an outcrop of the work of the surgeon on gall stones that all our modern knowledge of the clinical aspects of chronic pancreatitis has sprung. The acute form of pancreatitis was first recognised, and, with something nearly approaching to finality, described by one of the greatest of physicians—Dr. Fitz, of Boston. But of chronic inflammation, of stone, of cysts, and of the mimicries of cysts nothing was heard or known till the surgeon came bearing these gifts in his hands.

The question of chronic pancreatitis was first brought before the minds of surgeons by Riedel, who noticed that in many operations upon the biliary passages the pancreas was large, hard, and unduly firm. Little knowledge, however, sprung from this observation, until Mayo Robson, with his then unrivalled experience of cholelithiasis, showed the frequency and the clinical importance of pancreatitis, and convinced us all of its powers of mimicry both of carcinoma and of the calculous form of common duct obstruction.

Acute pancreatitis, so accurately described by Fitz, remained for long a desperate and often lethal disorder. The onset of the symptoms was so abrupt, their course so rapid, and the fatal event so precipitate that for many years surgeons were quite unable to realise the moment for swift intervention. When operation was undertaken it was generally upon the mistaken diagnosis of perforating ulcer of the stomach or duodenum. And it was not until Ramsay, in 1902, showed that the chief surgical indication here, as in the case of a phlegmon in the extremities, consisted in the relief of tension, that success began to attend the surgeon's efforts. Now it is a matter of very little difficulty to make an accurate and timely diagnosis of acute pancreatitis, and the recovery of the patient can generally be assured.

THE INFLUENCE OF INTESTINAL STASIS.

Among the most interesting and possibly one of the rich gifts of surgery to medicine is the hypothesis that intestinal stasis, with the associated condition of absorption of toxins, is responsible for many of the diseases which attack, not only the abdominal viscera, but even also parts remote therefrom. Perhaps no subject in medicine to-day has received more discussion, has been more bitterly assailed, more often attacked by derision rather than by argument, and more cheerfully supported than this. Its author, Arbuthnot Lane, is a man whose mind moves easily along new paths. He believes that the intestine itself is the factory in which the poisons are produced which cause, or make more easily possible, not only the various conditions I have named, but also such diverse and distant conditions as "rheumatoid arthritis," tuberculous diseases of bones and joints, diseases of the breast, cystic and malignant, of the thyroid gland, and many other conditions. At first it was supposed that the large intestine was the malefactor, and some slender support was possibly derived for the hypothesis from the work of Metchnikoff and others. More recently the delayed drainage of the small intestine has been held more blameworthy. The most exemplary instance of the effects of alimentary toxæmia occurs, perhaps, in the condition which may best be described as Lane's disease. The miserable chronic dyspeptic with sallow skin, dirty tongue, flaccid belly, offensive breath, dusky lips and nails, cold extremities, and constipation that is with some difficulty overcome, is restored to health with incredible rapidity when a short circuit is made between the ileum and the pelvic colon.

Medicine in its quest of knowledge may rightly levy a tribute from every other science with which it comes into contact. The experimental method, as a mode of inquiry, is not excelled in value by any other, and no experiments, I hold, can claim an equal rank with those which are a part of almost all surgical procedures. In every operation something may be learnt, not only of those disorders which call urgently for relief, but of other associated, or it may be separate, conditions which chance at the same moment to be present. The researches so carried out upon a human patient are performed with a sterner sense of responsibility and with a graver ritual, and are impressed by more relevant influences than attach to any other form of inquiry. Their results are accordingly of far higher value. Clinical research, when sedulously conducted and illumined by the disclosures made upon the operation table, afford the most accurate of all methods of investigation into the diseases by which man is attacked. The succour of an individual should mean also the taking of a step forward in the solution, or the better understanding of the manifold and perplexing problems of disease.

CHRONIC MEDIASTINITIS: ITS CAUSES, FORMS, SYMPTOMS AND TREATMENT.[1]

By Professor C. LIAN, M.D.,
Director of Clinical Medicine at the Faculty of Medicine of Paris.

[Specially Reported for this Journal.]

It is rather remarkable that in most text-books the only mediastinal diseases described are adenopathies and tumours, and nothing is said about chronic mediastinitis, although medical literature contains plenty of recorded cases to show that chronic inflammation of the mediastinum may exist without glandular enlargement, tumours or even pleural or pericardial lesions, giving rise to a distinctive clinical picture.

The principal factor in the causation of chronic mediastinitis is syphilis, and it is almost exclusively a tertiary manifestation. In nearly all the recorded cases it occurred in subjects whose attack of syphilis had been mild—so mild as to have escaped treatment—and in not a few it was associated with other syphilitic lesions of the mediastinum.

After syphilis, the commonest cause of chronic mediastinitis is tuberculosis. Authors do, indeed, refer to the occurrence of mediastinitis in connection with tuberculous tracheo-bronchial adenopathy, but seem to attach little importance thereto. Of course, it is often met with in connection with tuberculous cardiac symphysis, in chronic pericarditis and mediastinal pleurisy, but there are instances in which the symptoms are due exclusively to tuberculous mediastinitis. There is a third group of cases in which both these pathogenic influences are present, and then it is quasi-impossible to make out what share in the production of the symptoms is due to each of them respectively.

Among other rarer causes of mediastinitis are acute articular rheumatism, cancer of neighbouring organs, actinomycosis, and even traumatisms.

The symptoms of chronic mediastinitis vary according to the ætiology. Although the lesions are approximately the same no matter how caused—since the ultimate consequence is always more or less mediastinal sclerosis—the predilection of the particular agent for special mediastinal tissues, and the difference in the course according to origin, give a special cachet to the affection. I shall begin with syphilitic mediastinitis, since this is the most frequent and characteristic form, at any rate in the adult.

Pathological investigation shows that the lesions in syphilitic mediastinitis are not equally distributed throughout the mediastinum. The inferior form seems to belong more particularly to the tuberculosis, but even in the superior mediastinum the sclero-gummatous lesions tend to predominate in particular parts, entailing a different symptomatology according to the part attacked.

In most instances it is round the superior vena cava and its branches that the inflammatory process is localised, so that the syndrome of obliteration of that vessel is common in syphilitic mediastinitis. In other cases, the mediastinitis displays a tendency to surround the air passages constituting the respiratory form.

There are also cases in which the lesions are more extensive and give rise to almost the complete mediastinal syndrome. On the other hand, the mediastinitis may be more or less latent, revealing its presence merely by a few symptoms which are but rarely traced to their real cause.

Syphilitic Mediastinitis with Obliteration of the Superior Vena Cava.

The onset is usually slow and progressive. The patient complains of respiratory oppression, especially marked on effort, sometimes accompanied by distressing attacks of pain, with a sensation of precordial constriction and tachycardia. There is often obstinate headache, relieved by epistaxis which may be very free. One symptom is invariably present, *viz.*, when the patient stoops down to pick up an object the face becomes cyanosed and the patient experiences giddiness and noises in the ears.

Gradually the cyanosis becomes permanent, the face is puffy and the eyes are more prominent. The thorax, neck and upper limbs become œdematous, and at the same time the dyspnœa increases and the headache is more refractory. Sometimes, however, the onset is so sudden that all the symptoms may be present within a few hours.

At the stage of full development three symptoms attract our attention, all due to progressive obliteration of the superior vena cava, *viz.*, œdema limited to the upper part of the body, cyanosis and the presence of a well-marked network of subcutaneous veins.

The œdema almost always begins in the face, thence spreading to the neck, upper limbs (beginning in the hands), and, lastly, the thorax. It is not rare for this to proceed *per saltum*, as, for instance, after a violent attack of cough. The face is puffy, the features partly obliterated ; in fact, it gives one the impression of a fictitious obesity. The cheeks are widened, giving the head the shape of a pear The mucous membrane is infiltrated and the mouth is pasty. The neck is swollen, especially at its base. The supraclavicular hollows are the seat of an elastic resistant swelling. In the limbs the œdema soon becomes hard and no longer pits on pressure. The œdema may not be symmetrical. The front of the thorax and the breasts are œdematous, but seldom the back. This is easy to understand, seeing that the intercostal veins have a double current, determined by the position of the valves. One runs forward to the internal mammary, ending in the superior vena cava ; the other backwards, discharging into the azygos. Now the azygos system constitutes an anastomotic bridge between the superior and inferior venæ cavæ, so that the venous blood from the back of the thorax can pass directly into the inferior vena cava (*a*).

If the œdema persists we soon get actual pachydermia.

The cyanosis accompanying the œdema gives the latter a very special cachet. The face is bluish-red, especially the lips, nose and ears. The eyes are turgescent, prominent, and the ocular conjunctiva is injected and œdematous. The whole of the upper part of the body is of a slate-blue tint, which is in startling contrast with the normal lower half. The cyanosis is intensified by effort of any kind, especially when the patient bends forwards, backwards or sideways.

We now witness the rapid formation of a collateral circulation, especially on the thorax, where a network of blue veins forms. If this takes place suddenly, as it sometimes does, we may get veritable echymoses due to the rupture of small veins. The jugular veins are distended, and they may remain soft or be felt as a venous cord due to the extension of phlebitis from the vena cava.

The obliteration of the superior vena cava also determines other signs of circulatory disturbance, as, for instance, obstinate headache, dazzling, vertigo and noises in the ears. Sleep is agitated, unrefreshing, and all the signs of venous compression are increased in the horizontal position. The memory is impaired, and there is confusion of ideas or there may be a tendency to

---

(*a*) The azygos major has only one valve in its course, and this almost always insufficient.

coma or convulsions. Then, too, the dyspnœa becomes more pronounced and may be accompanied by attacks of suffocation and violent paroxysms of cough followed by blood-stained sputum. Apart from these little attacks of hæmoptysis from time to time the patient suffers from copious epistaxis, but tachycardia is the only manifestation of circulatory disturbance.

The general health remains fair, the temperature is normal, and, except for loss of appetite, the digestive apparatus is not hampered. The urinary secretion is apt to be scanty, and the urine may contain albumen.

All the symptoms enumerated above are consequent upon obliteration of the superior vena cava. The mediastinitis only manifests its existence by inconstant signs, very difficult to identify in the midst of the dramatic concomitants. This form may run on to a fatal termination, the dyspnœa becomes asphyxial, the nervous troubles are aggravated, and the patient succumbs to asphyxia or to coma or, it may be, suddenly expires in syncope.

The prognosis, however, is not always as gloomy as this, because the organism sometimes makes a gallant attempt to accommodate itself to altered conditions by the development of an anastomotic chain of subcutaneous veins between the two cavæ. Improvement is particularly rapid when antisyphilitic treatment has been early instituted, and may be very manifest within a fortnight. Otherwise it takes a month or two. Thereupon the symptoms become attenuated and the patient reaches the third stage.

The salient feature of the third stage is the complete establishment of the collateral circulation. Over the upper two-thirds of the front of the thorax, extending freely over the roots of the arms and the neck, even invading the lower part of the face, we see a thick, venous network, with meshes elongated vertically. From the lower part of this network run collecting trunks which communicate with veins belonging to the inferior vena cava system. Some of them go to the xyphoidal and umbilical veins. The others, as a rule two large trunks, run almost vertically to join the cutaneous branches of the inferior epigastric and especially the long cutaneous thoraco-epigastric vein.

This distribution suffices to distinguish the collateral circulation under consideration from any other. It is quite different from that of exclusive obstruction of the inferior vena cava, in which the dilated veins are mostly on the lateral walls of the abdomen and culminate almost exclusively in the axilla, and it can easily be differentiated from obstruction of the portal circulation, which is most marked over the insertion of the diaphragm and the pit of the stomach, in which the collecting trunks empty themselves in the axilla and the medio- and parasternal veins. It is not quite as easy to differentiate it from the collateral venous system in portal hypertension co-existent with obstruction of the inferior vena cava, because in that event there is dilatation of the subcutaneous veins both on the thorax and on the abdomen, but the dilated veins are at their maximum at the base of the thorax or on the abdomen and the blood current is from below upwards.

I dwell upon this collateral circulation because it is almost the only symptom of the third period of mediastinitis with obliteration of the superior vena cava. Side by side with the form associated with obliteration of the superior vena cava must be placed the one in which there is obliteration of one of the two brachio-cephalic trunk veins. The signs are the same but limited to one half of the upper part of the trunk. The collateral circulation in these cases is rather peculiar in that the veins form a rich network with *horizontal* meshes anastomosing freely with the veins of the arm, and the collecting trunks empty into the innominate veins of the trunk.

In other instances the respiratory disturbances are most in evidence. Commencing with dyspnœa, at first only after effort but subsequently becoming constant, this is dyspnœa of inspiration without any increase in the number of respiratory movements; there may be whistling or stertor, possibly even supra- and sub-sternal retraction. This dyspnœa is often accompanied by cyanosis, but no œdema. On physical examination we may find abolition of the vesicular murmur in contrast with the normal resonance of a lobe or of the whole lung. Should there be at the same time pressure on the recurrent nerves, we get vocal symptoms with attacks of suffocation which may rapidly become extremely grave. These cases are the more formidable seeing that, as a rule, there is not only compression of the air passages but also sclero-gummatous lesions of the walls of the air-passages.

Inferior syphilitic mediastinitis is uncommon, but it is mentioned by various authors, especially Hutinel. The inferior form is almost always consequent upon tuberculosis. There is also the extensive form which sets in with respiratory symptoms; intense dyspnœa, cyanosis and other signs of mediastinal compression. In a case reported by Dieulafoy the disease was ushered in by a series of minor signs pointing to interference with the circulation in the superior vena cava: headache, running at the eyes, vertigo, and dysphagia followed by dyspnœa and ultimately œdema, with the establishment of a collateral circulation and recurrent nerve symptoms. Antisyphilitic treatment is most efficacious in these cases, which would otherwise run a rapidly fatal course.

Abortive Forms.—Apart from the cases which run an acute course, there are many in which the mediastinal lesions are less extensive, or at any rate do not involve important mediastinal organs. The patient merely complains of a little effort dyspnœa, which nothing in his lungs or circulation seems to explain. He may have occasional attacks of retrosternal pain. In other cases there is only tachycardia or bradycardia of unknown origin. In a case under my care the only symptom was repeated glottic spasm. In other instances dysphagia or dysphonia is the only, or at any rate the principal, symptom, and this is extremely likely to be put down to aneurysm of the aorta. Lastly, there may be no particular functional symptoms, only more or less pronounced collateral circulation, testifying to circulatory embarrassment in the domain of the superior vena cava.

It is in these cases of abortive mediastinitis that we must look for the signs and symptoms peculiar to mediastinitis proper. Inspection may reveal pluricostal systolic retraction in the precordial region or below and outside the inferior angle of the scapula (Broadbent), though these are symptoms mostly met with in connection with mediastino-pericarditis. Percussion rarely yields much information, though it will sometimes show dulness outside the manubrium sterni or in the inter-scapulo-vertebral space. Among other signs observed by various authors are tracheal tugging (absent in three cases of my own), Kussmaul's pulsus paradoxus and inequality of arterial tension in the two radials when the patient is lying down, but disappearing in the erect position. All these signs are untrustworthy, and in these abortive forms we shall have to rely mainly on radiography in order to arrive at a diagnosis.

(*To be continued.*)

APEX-TREATMENT FOR PULMONARY CONSUMPTION.

By WILLIAM EWART, M.D.CANTAB., F.R.C.P.,

Consulting Physician to St. George's Hospital and to the Belgrave Hospital for Children; formerly Assistant Physician and Pathologist to the Hospital for Consumption, Brompton.

III.

"THE MACHINE, THE FUNCTIONS, AND THEIR CONSTANTS."

Should there be an Apex-treatment?—This would need no comment, were any blank less fatal. Consumption and death itself turn upon our behavour to the apex in its earliest trouble. Then, or never, is the time for simple means with great effects. Later the means are arduous; but meagre and slow the results. Our early tuberculosis has been treated so far by a general hygiene which is mainly atmospheric; but its local culture and the lung we have simply watched. Will the lesion remain closed, or is it going to open? That should be, not our "expectant" but our "active" concern. The worst is that, when after the failure of our expectant apex policy, we are moved to action by the advent of the dread open stage, we are still without any proposition as to the local management of the apex, which is now much more urgent and many times more difficult. It is true, that the rest we enforced was some form of treatment. The on-coming of the open stage in spite of it might mean that there had not been "enough" rest:—then why not "more" of it? But it is by no means less consistent to suppose that there might have been "too much" rest. "Who will decide?"—This echoes back: "Who will try?" But let us now pass to our third, all important question.

Can there be an Apex-treatment?—Many, perhaps; but very few of them simple and safe. Local "specific" immunisation by bacillary methods begs the question. It were no longer necessary if we knew the secret of a general immunisation against tuberculosis. That larger endeavour lies beyond our present clinical field. We can deal only indirectly with the infection, but much more directly with the lung; and it is in that direction that the discussion has lately shifted. The latest proposition in the Freund-Hart theory is that the phthinoid thorax is not "congenital," but itself the result of an early "infantile" tubercular blemish. This is not inconceivable as we are familiar with a converse transformation of the chest at a later age, when the drooping ribs of a "paralytic thorax" will rise and expand in abdominal plethora, or under strenuous muscular hygiene. This is a fresh hope added to our mechanical policy. As a fact, the "pulmonary" field is mechanical from end to end; in local predisposition and immunisation, in the localisation of tuberculosis, and in the local spread of the resulting phthisis, and also in the local indications for its treatment. We are still working exclusively under the formula, "The Seed, the Soil, and their Variations." We should now work under a second formula for less dilatory results: "The Machine, the Functions, and their Constants."

Can there be any "safe" Apex-treatment?—All disease, barring massive intoxications, slides from physiology into pathology. Consumption like the rest has its "physiological" zone, beyond which ingravescent pathology limits the possibilities and increases the dangers of treatment, till it rushes us into the heroic for rescue. How much less dangerous our artificial pneumothorax, if it were administered to a patient hardly yet impaired in strength, to a lung almost undiminished in its physiological efficiency, and with the reserve not of a tainted or suspected, but of an absolutely sound second lung! The same applies to the "pretubercular" and to the early "tubercular" use of tuberculin. Yet prudence witholds the syringe. Even then the risk is too great. Safety is not the characteristic of pathological remedies.

The safe remedy is the physiological one, applied at the physiological period. This points to our limited opportunities in range and in time. Late recovering consumptives are cured by their bacillus; some of them, too, we believe, by our tuberculin. Both reap the full benefit of their long specific immunisation. If that too precarious and wasteful benefit is to be forestalled, this can only be by the physiological pulmonary factor; which is mainly, so far as we can yet perceive, a mechanical factor, since we have reluctantly given up the hope of overpowering the bacillus with well-meant antiseptic inhalations, although these do not share the element of risk which belongs to the more drastic methods of the general "intravenous" antisepsis of Maguire and Dewar, or of the local intra-apical iodised injections of V. d'Amico (*a*).

Not inconsistently, formula I, the bacillary formula of variation, influences our treatment, and formula II., the physiological formula of constancy, rules our prevention. The disturbed physiology of disease is ever uncertain, and all sound treatment has to be variously planned to meet its unforeseen individual vagaries; but none the less under one unalterable law—that life itself is the true healer, and that heart, lung, and stomach, under the hegemony of the nervous system, have to work out the cure. We have broken up the idols of the pharmacopœia, but we cannot afford to be without the help which they symbolised, above all the help of Strychnine and of Digitalis handed down to us by Niemeyer, and of Oxygen which alone we have remembered. "The Trend of Modern Pharmacological Research" so lucidly traced out by Sir Wm. Whitla (*b*) brings us back to that primal allegiance, which is one of the missing arches for what we conceive to be the only "thorough treatment" of consumption; the other being the mechanical factor, centred upon perpetual cardio-pulmonary collaboration in the mechanism of life. Heart and lung are so linked that the one either pulls, or drags upon the other. Each breath we draw circulates the blood for the pumping heart; and the strength of the heart day by day governs the healing work of the lung for that day. In truth the heart is the dynamic centre of the cure: to be fostered from the first, constantly watched, and, if necessary, judiciously aided by any drugs such as strychnine, which can also help an overworked stomach and a depressed cerebro-spinal system.

CLINICAL RECORDS.

INFLUENZA AND TYPHUS.

By EUSTACE THORP, L.R.C.S.Edin., D.P.H. Belf.

The recent epidemic of typhus fever in the west of Ireland illustrates the difficulty of differentiating these two diseases. Some of the cases, the earliest, were diagnosed as influenza and were admitted to hospital as such, and only when a typical case occurred was their real nature discovered. Other epidemics have progressed in the same way, the disease simulating influenza of a severe type. The question arises—what is influenza, has it any relation to typhus? The sporadic cases of the latter disease frequently appear during an influenza outbreak. Typhus has disappeared with the improvement of hygienic conditions, and the view might be held that influenza is a modified form of typhus occurring under these better conditions, but liable under certain insanitary conditions to revert to the malignant form, thus accounting for the sporadic cases. When such a case does appear it is not uncommon to find influenza present in the patient's family.

The more one studies the symptoms and sequelae of the two, the greater does the similarity become. Both are easily spread, and affect the very young and the very old chiefly, and in the latter the severity and mortality rate are heaviest on those suffering from complaints of the respiratory system. The prostration of the two diseases show another striking resemblance.

A combination of the so-called types of influenza would produce a disease strongly resembling typhus without rash, and patients suffering from influenza frequently show symptoms referable to two or all the types. The differential diagnosis between the two diseases—malignant influenza or typhus, may turn, and often does, upon the presence of a rash, yet true typhus, though prone to assume a septic condition, especially when epidemic and appearing under unfavourable circumstances, may run its whole course without petechial or any marked putrid condition. On the other hand, hybrid outbreaks of influenza are known, notably that reported from Hertfordshire, where rashes simulating typhus and scarlatina were found, while others resembled cerebro-spinal meningitis.

In children, as a rule, typhus pursues a mild course, rashes are often atypical, transient, missed, or absent, and it is possible that in the recent English epidemic amongst children there was a proportion of typhus cases. Overcrowding in a common atmosphere has long been recognised as disastrous in typhus, and more recent experience has shown this to be so in the case of influenza, as regards transmission of infection, intensification of type, and retardation of recovery. It is not too much to suppose that a form of illness like influenza might occur amongst those living under good hygienic conditions, whilst in bad surroundings a more severe type, such as typhus, might well be expected, this accounting for the fact that influenza more commonly attacks the well-to-do living normally under good hygienic conditions, whereas typhus almost invariably attacks those living under the worst possible conditions.

Bacteriologically Pfeiffer's bacillus is recognised as a causative organism in true influenza, but other organisms are found in types where the *B. influenzæ* is absent. No causative organism has as yet been identified for typhus, but evidence points to a minute germ.

Though not suggesting that the two diseases are one and the same, one's attention is drawn forcibly to the following facts:—As typhus has been eliminated, influenza has become more prevalent; typhus outbreaks frequently occur at the height of influenzal epidemics; influenza appears in hybrid forms; lastly, the two diseases present a strong resemblance in symptoms and sequelæ.

We must pause and reflect over their significance, considering the possibility of a relation existing between them, such as exists among the variolous group.

I have to thank Dr. W. R. MacDermott for information, drawn from his experiences in days when typhus was a more common disease.

OPERATING THEATRES.

HAMPSTEAD HOSPITAL.

Nine Operations for Hernia.

The following series of cases were operated upon by Mr. Jackson Clarke:—

Case 1.—Right Inguinal Hernia.—Man, æt. 48, furrier. Admitted November 20th, 1911; discharged December 17th, 1911. Feeling of weakness and lack of support in right groin. No swelling seen. Three months' history. *Operation.*—November 22nd; C.E—$CHCl_3$. Direct variety of hernia. Sac contained a lipoma and piece of omentum. Radical cure. Wound healed by first intention. Some post-operative bronchitis.

Case 2.—Left Inguinal Swelling.—Boy, æt. 11. Admitted May 1st, 1911; discharged May 25th, 1911. *Operation.*—May 3rd; C.E.—ether. Canal opened. No sac found. External oblique aponeurosis weak; strengthened with sutures. *Recovery.*—Uneventful. *Result.*—Cured.

Case 3.—Strangulated Right Inguinal Hernia.—Woman, æt. 44. Admitted April 7th, 1911; discharged May 1st, 1911. Two years' history of right inguinal hernia. Two days acute pain and vomiting. Hernia reduced by taxis on admission. *Operation.*—April 12th; C.E.—ether. Sac markedly thickened. Radical cure. Fascia covering pectineus stitched to Poupart's ligament as a precaution, although no signs of femoral hernia were present. Uneventful recovery.

Case 4.—Right Inguinal Hernia.—Man, æt. 43. Admitted May 29th, 1911; discharged June 28th, 1911. Radical cure five years previously at another hospital. On day of admission fell off the ladder of a dust cart. Hernia suddenly came down again on same side. Reduced on admission. *Operation.*—June 7th; C.E. Hernia cut down upon. Sac found to extend from external ring to conjoined tendon, and was much thickened. Portion of the bladder was found in sac. Radical cure performed. Wound healed by first intention. Some post-anæsthetic bronchitis.

Case 5.—Strangulated Femoral Hernia.—Woman, æt. 78. Admitted March 7th, 1911; discharged April 1st, 1911. History of two days' vomiting; Stercoraceous on admission. Bowels not open four days. Tenderness and pain over the right femoral hernia, the size of a pigeon's egg. *Operation.*—On admission; $CHCl_3$—CE—ether. Incision over mass. Sac contained dark, cherry-coloured bowel, which bled. Hernia director inserted and constricting band divided. Radical cure. Uneventful recovery.

Case 6.—Strangulated Inguinal Hernia.—Man, æt. 52. Admitted March 28th, 1911; discharged April 5th, 1911. Twenty-four hours' history of painful swelling in scrotum. Bowels open, with traces of blood. No vomiting. Vomited eight times after admission; stercoraceous. Strangulated inguinal scrotal hernia on left side. Phimosis. *Operation.*—March 29; C.E. Incision over swelling. Sac contained cherry-coloured small intestine. Left testicle swollen, black and gangrenous. Constriction divided and bowel returned. Sac not ligatured. Left testicle removed. Canal sewn up. Circumcision. Rapid and uneventful recovery.

Case 7.—Strangulated Right Inguinal Hernia: Left Inguinal Hernia: Bilateral Varicocele.—Man, æt. 38, caretaker. Admitted April 23rd, 1911; discharged June 13th, 1911. Four years' history of right inguinal hernia, reducible; 36 hours' strangulation. Duration of left inguinal hernia and bilateral varicocele not mentioned. Temperature, 99°; pulse, 78. *First operation.*—On admission; C.E.—ether. Herniotomy and radical cure. Sac had a very broad base and contained some blood and tightly nipped bowel, showing some ulceration. The varicocele was very large and among the veins. No spermatic artery found. Large external ring. Excision of veins of pampiniform plexus on same side. *After-result.*—Slight bronchitis of short duration. Some serous, cloudy exudation from upper part of wound. *Second operation.*—May 10th; C.E.—ether. Radical cure on left side, and large varicocele radically cured. May 13th, gangrene of scrotum discovered (? which side). Right inguinal wound still oozing. Cellulitis of left groin. *Third operation.*—C.E.—ether. Scrotum and groin opened up freely. Right testis removed. Transferred to isolation. Four-hourly irrigation *c* iodine solution in water, dr. 1 ad oj. Satisfactory progress was made subsequently. The healing of the gaping wound in the left groin was hastened by a tension suture. Patient left hospital in good health with a granulating wound no bigger than a shilling piece.

Case 8.—Strangulated Umbilical Hernia.—Man, æt. 58, caterer. Admitted July 3rd, 1911; died July 16th, 1911. Four years' history of reducible umbilical hernia. First became irreducible three days ago. No vomiting. Constipation. Temperature, 99°; pulse, 110. *Operation.*—On admission; ether. Large hernia. Sac contained a large loop from the upper, and a smaller one from the lower, part of the small intestine. All contents of sac gangrenous. Upper loop resected, and union effected by a Murphy's button. The lower loop, after resection, was closed by a lateral anastomosis. Following day fæcal vomiting commenced. *Second operation.* July 5th; C.E. Murphy's button removed and replaced by a lateral anastomosis. Patient died the next day.

Case 9.—Strangulated Right Inguinal Hernia.—Man, æt. 64, bricklayer. Admitted May 20th, 1911; discharged June 30th, 1911. Right inguinal hernia (reducible) for many years; strangulated twelve hours. *Operation.*—On admission. Temperature, 97.6°; pulse, 60. Hernia cut down upon. A large mass of bowel in the sac, and surrounding parts very œdematous. Peritoneum covering of intestines congested, but fit to be returned to abdomen. Fourteen days afterward patient complained of severe pain, and it was found that hernia was down again and irreducible. Mr. Thomson Walker operated, and found that the appendix and part of the cæcum had come down, and that there was no sac covering them. Tissues very œdematous. Pus along track of old wound deep down. Discharged with a truss in a satisfactory condition. He had a hernia on the left side which it was considered inadvisable to operate upon, as patient was a fat man with a troublesome chest when kept lying in the prone position.

In his comments on the cases Mr. Jackson Clarke said:—From among a series of abdominal cases (*a*) I have chosen some that illustrate common hernias. In Case 1 it will be noted that the hernia was of the direct variety. Among the many hernias I have operated on in the past five years quite a number have been of this kind—one in a child. In Case 2 there was no hernia, strictly speaking, but only a cleavage in the fibres of the external oblique leading to a bulging of the abdominal wall. Case 3 reminds one that inguinal hernias are quite common in women. After operating on the inguinal hernia, provision was made against the occurrence of a femoral hernia subsequently. Case 4: The term "radical cure" means Bassini's operation in these notes, unless otherwise stated. A thickened bladder may easily be exposed in the operation for inguinal hernia without its being herniated, but in this case there was a distinct hernia of a portion of the bladder. Case 5: Here the condition of the bowel was serious, also the general state of the patient, but in spite of her age she recovered rapidly. It is important to examine the part of the bowel actually nipped to see that it is not necrotic before returning such intestine to the abdomen. Case 6 is similar to Case 5. Case 7 was a combination of badly strangulated hernia with a varicose state of the scrotal veins and a varicocele of unusually large dimensions. The events subsequent to the first operation called for and received prompt and extensive secondary measures. Case 8 shows the importance of having umbilical herniæ surgically treated before they become past all help: in this instance the patient was given the only chance. Case 9 shows how a constant cough may cause troublesome complications after an operation for hernia. I have to thank my colleague, Mr. Thomas Walker, for coming to the rescue in my absence.

(*Comments on cases published July 23rd.*)

Mr. Jackson Clarke said that he would refer to the prostatic case first, having been recently reminded of this case by the patient coming to report himself. The tumours after removal strongly recalled uterine myomata, but microscopic examination proved them to be adenomata. The patient had remained perfectly free from urinary symptoms during the three years that had elapsed since the operation, and in the interval had been in the hospital for operation on a large inguinal hernia, the result of which had been as satisfactory as that for the prostatic condition. The case offers a practical lesson to those who are about to operate on what seems like a typical general enlargement of the prostate: if enucleation should prove to be difficult, do not persist until an examination by palpation and inspection, either direct or by a speculum inserted into the supra-pubic wound, has excluded the condition here described. With regard to the case of abdominal adhesions and gangrenous gut, the peritoneum being infected and the pelvic cavity full of septic fluid, drainage was clearly indicated, and the happy issue of the case vindicated the rather lengthy period during which the drainage was kept up. A large rubber tube, with a strand of ribbon gauze lying loosely within it, was used at first, the gauze being changed and the contents of the tube being aspirated twice a day. After the 4th day a small quantity of a lotion made by adding a drachm of Tr. Iodi to a pint of saline solution is run into and sucked out of the tube several times; the outer end of the tube is covered by a dressing of cyanide gauze passed through 1/40 carbolic. At the end of a week the large tube is changed for a smaller one. With these precautions the risk of a tube keeping up instead of removing infection is obviated.

The case of tubal pregnancy is a typical one of its class. Case 3: The short-circuiting operation was only a palliative measure. It was effected by lateral anastomosis and gave great relief to the patient. Case 4: This is a brief record of serious and complex lesions. The word "cholecystectomy" is a clerical error. The natural opening in the gall-bladder was only enlarged and a drain inserted. The stone which caused the perforation had evidently escaped during the attack of pain, which appears to have simulated renal colic. Case 5 is interesting as an instance of a retro-peritoneal perforation of the duodenum. The note "Fluid escaping from second part of the duodenum" refers to my observation during the operation of a dark-green, diffuse, retro-peritoneal infiltration around the second part of the duodenum. In making the posterior drainage track the second part of the duodenum was lifted from the kidney.

At Acton Cottage Hospital the other day Dr. E. W. Lowry and Dr. F. W. James, late Chairman and Secretary respectively of the Ealing Division of the British Medical Association, were presented with silver salvers by "some members of the medical profession resident in the Ealing Divsion of the British Medical Association, in appreciation of their strenuous work during the crisis of 1913."

(*a*) Reported for me from the Hospital Notes by Mr. V. C. [illegible]el.

SPECIAL REPORTS.

THE EIGHTY-FIRST ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION, HELD AT BRIGHTON, 1913.

[By Our Special Representative.]

THIRD ARTICLE.

THE WORK OF THE SECTIONS.

Section of Bacteriology and Pathology.

An interesting paper was read on the Wednesday by Mr. Rupert Farrant (London) on "Hyperthyroidism," chiefly from the experimental standpoint. Drs. E. T. McWeeney, W. M. Crofton, and H. F. Moore presented a paper on "Paratyphoid Infection," in two cases of which vaccines had been used with success. An excellent demonstration was given by Dr. v. Wasielewsky (Heidelberg) on the different types of amœbæ. Dr. Miller Galt (Brighton) read a paper on "The Value of Blood Counts in Diagnosis." On the following morning a joint discussion took place with the Section of Pharmacology, Therapeutics and Dietetics on "Anaphylaxis" which was opened by Prof. W. E. Dixon, followed by Prof. G. Sims Woodhead, "General Pathological Aspects"; Drs. Thiele and Embleton, "Special Bacteriological Aspects"; E. W. Goodall, "Clinical Aspects"; H. H. Dale, "General Experimental Point of View." The last day was occupied with papers by the Staff of the John Howard McFadden Research Fund on "The Jelly Method of Staining Cells Alive," and by Dr. R. M. Buchanan (Glasgow) on "*Empusa Muscæ* as a Trajector of Bacterial Infection," among others.

Section of Climatology and Balneology.

Dr. W. J. Tyson (Folkestone) opened a discussion on the first day on sea bathing, which was considered in a comprehensive manner and, as might be expected, the remarks of the speakers upon this subject were freely quoted in the lay Press. On the Thursday, Dr. Neville Wood introduced the subject of the international aspect of health resorts, followed by Dr. W. Gordon (Exeter), Dr. F. T. Paley, the President (Hove), Dr. D. D. Brown (Harrogate), and others. Several interesting papers were read the following day, including one by Dr. H. de Carle Woodcock on "Tuberculosis from the Climatological Point of View"; Notes on Egypt and the Nile as a health resort, by Mr. Shepherd Boyd; and "Massage in Fibrositis and Other Painful Affections," by Dr. R. Ackerley.

Section of Dermatology.

In his opening remarks, the President, Dr. J. H. Sequeira, referred to the action taken by Sir Malcolm Morris in initiating a movement for a Royal Commission to inquire into the treatment and prevention of venereal disease, and expressed his admiration of the courage shown by certain newspapers in publishing a letter on the subject signed by 40 leading British medical men. Sir Malcolm Morris, who also spoke, emphasised the mistaken character of a policy which forbade the mention of such matters in the public Press. He said England was behind other countries in the prevention and public treatment of these diseases, and reiterated the demand for a Royal Commission. A discussion was then opened by Dr. H. G. Adamson (London) on the fungous affections of the glabrous skin, illustrated by lantern slides, followed by Prof. Alfred Bolam (Newcastle), Dr. G. Pernet (London), and others. On the following day a discussion on the nature, causes, and treatment of lupus erythematosus was opened by Dr. J. M. H. McLeod (London), followed by Prof. A. Bolam, Dr. Alfred Eddowes (London), Sir Malcolm Morris, R.C.V.O., Dr. Holdin Davis (London), Dr. Pernet, and Dr. A. W. Williams (Brighton). A paper was then read by Dr. Norman Meachen (London), on "The Treatment of Tuberculosis of the Skin by Means of Copper." The last morning was occupied with several interesting papers. Dr. J. L. Bunch (London) read one on "The Treatment of Skin Diseases by Solid Carbon Dioxide"; Dr. David Walsh (London), "Circulatory Disorders in Relation to Alopecia Areata and Other Forms of Baldness"; Dr. F. Gardiner (Edinburgh), on "A Case of Acne Necrotica"; Dr. Haldin Davis, on "Ointments"; Dr. A. W. Williams, on "The Treatment of Chronic Ulcer of the Leg"; Dr. S. E. Dore (London), "The Use and Action of X-rays in Psoriasis and Other Skin Diseases"; and Dr. L. T. Hobson, on "The Treatment of Common Skin Diseases at the Harrogate Spa." A number of interesting cases were shown before the meetings.

Section of Diseases of Children, Including Orthopædics.

Dr. F. J. Poynton (London) introduced a discussion on the Wednesday on "Affections of the Heart in Childhood," followed by Dr. Carey Coombs (Bristol), Dr. Chaffey (Hove), Dr. Mary Murdoch (Hull), Dr. R. Miller (London), Dr. W. P. S. Branson (London), and Dr. Naish (Sheffield). Dr. J. H. Nicoll (Glasgow) then read a paper on "The Surgery of Childhood," a plea for the more extensive use of the outpatient department for operations on children. On the Thursday, Mr. T. Openshaw, C.M.G., opened a discussion on "The Choice of Methods in Dealing with Paralytic Deformities in Children," followed by Prof. Foerster (Breslau), and Messrs. Robert Jones (Liverpool), Edred Corner, Laming Evans, F. W. Goyder, Kellett Smith, R. Ollerenshaw, and others. The concluding session was occupied by the discussion on "The Diagnosis and Treatment of Acute Inflammatory Affections of the Abdomen in Children," opened by Mr. C. B. Lockwood, and a paper by Mr. Blundell Bankart on "The Treatment of Poliomyelitis."

Section of Electro-therapeutics.

Dr. W. Deane Butcher, the President, introduced Prof. C. G. Barkla, of King's College, London, who delivered an address on the subject of "Secondary X-ray Radiations in Medicine." Dr. A. F. Hertz (London) next read a paper on "Suggested Normal Standards of the X-ray Examination of the Alimentary Canal." Other papers were by Dr. Ironside Bruce on "Collargol Injections in the Diagnosis of Diseases of the Urinary Tract"; by Dr. A. C. Jordan on "Cardiospasm"; and by Dr. Reginald Morton on "The Present Position of the X-ray Diagnosis of Pulmonary Tuberculosis." On Thursday there were numerous papers, including one by Dr. Lewis Jones on "The Use of Condensers in Electrical Treatment"; Dr. C. F. Bailey, on "Electro-therapeutics in Neuron Lesions"; Dr. J. D. Harris on "Secondary X-rays in Connection with Ionisation." A discussion was opened on Friday on "The Use of the Gamma Radiations in Surgery," opened by Sir A. Pearce Gould and Dr. Robert Abbe (New York). Prof. Gauss (Freiburg) read a paper before a joint meeting of this section and that of Gynæcology on "The Radio-therapeutic Treatment of Gynæcological Cases at Freiburg." Other interesting papers closed the day's proceedings.

Section of Gynæcology and Obstetrics.

On the Wednesday a discussion was opened by Mrs. Scharlieb (London) on the best methods of dealing with malpositions of the uterus, with special reference to retro-displacements and prolapse, followed by Dr. Hans Schlimpert (Freiburg) and Professor Corby, M.D. (Cork), Dr. A. E. Giles (London), Mr. Christopher Martin (Birmingham), Mr. Cuthbert Lockyer (London), Miss Frances Ivens (Liverpool). Dr. W. Ritchie (Glasgow), and Dr. R. Dickinson (New York). The next day's proceedings opened with a discussion on affections of the urinary tract, complicating pregnancy, introduced by Sir J. Halliday Croom, followed by Drs. H. Williamson, H. O. Nicholson, W. H. P. Newnham, and Messrs. F. Edge, Bryden, Glendining, and Child. On Friday, Dr. A. E. Giles read a paper on "Reasons for Early Operation on Uterine Fibroids," followed by a conjoint paper on "The Significance of the Wassermann Reaction in Gynæcological Diagnosis," by Drs. A. L. McIlroy, H. F. Watson, and J. H. McIlroy. Dr. Hans Schlimpert contributed a paper on "Aberhalden's Serum Reaction of Pregnancy."

Section of Laryngology, Rhinology, and Otology.

A discussion was opened on the first day by Dr.

W. Milligan on the *technique* and after-treatment of the radical mastoid operation, followed by Dr. Dundas Grant, Sir R. Wood, Dr. Jobson Horne, Dr. Watson-Williams, Dr. Wyllie, Dr. Syme-Mackay, Dr. Sydenham, and Dr. Davis. Mr. Herbert Tilley and Sir R. Wood opened a discussion next morning on the care of patients after operations on the nose and nasopharynx. Dr. P. Watson-Williams gave a demonstration at the Brighton Throat and Ear Hospital on exploration of the accessory sinuses of the nose. Professor Owen Richards (Cairo) contributed a paper upon "Rhino-scleroma." Dr. W. Hill demonstrated a new form of oro-tracheal catheter for administering anæsthetics without admission of blood to the air-passages. The concluding session was occupied by papers by Drs. A. Maurice (Paris) and H. Humphris on "The Re-education of the Powers of Hearing." Mr. J. F. O'Malley read a paper on "Suggestive Points of Analogy in Oto-Sclerosis and Arthritis Deformans." Mr. G. Seccombe Hett discussed the physiology, anatomy, and embryology of the polatine tonsils, and Dr. Jobson Horne was heard on tumours of the ventricle of the larynx.

SECTION OF MEDICAL SOCIOLOGY.

This section was the largest attended of all, and at the opening meeting on the Wednesday, after some introductory remarks by the President, Dr. R. J. Ryle, M.A., J.P. (Brighton), a discussion on eugenics was introduced by Mr. Edgar Schuster, M.A., B.Sc., the first Galton Research Scholar, followed by Dr. Harry Campbell, who pointed out that it was not at present advisable to put any legal restraint upon biologically right marriages: it was better to rely upon the individual eugenistic conscience, which should be carefully fostered in the race. He was followed by Dr. Stewart Mackintosh, Mr. F. J. Lidbetter, Sir James Barr, Miss A. H. P. Kirby, Dr. Dunlop, Prince Kropotkin, Dr. C. V. Drysdale, Dr. C. Saleeby, Mgr. Canon Johnston (Brighton), Dr. Wynne (Wigan), Dr. Ernest Wood, and Mrs. Arthur C. Gotto. On the next day the subject of crime and punishment was discussed, the principal speakers being Dr. James Scott (late Governor of Holloway Prison), Dr. C. A. Mercier, Sir H. Bryan Donkin, Mr. A. O. Jennings, LL.B. (Brighton), the Rev. C. B. Simpson, M.A., Prince Kropotkin, and Captain A. St. John. A resolution was adopted to the effect "that it be recommended to the Council of the Association to appoint a Committee of Members of the Association, with power to co-opt others who are not members of the medical profession to consider the present state of the law with regard to the legal responsibility for crime, and to issue a Report with recommendations to the Council." On the Friday, Prof. Benjamin Moore, M.A., D.Sc., F.R.S., introduced the subject of "Hospitals in Relation to the State, the Public, and the Medical Profession"; followed by Dr. J. G. Gibbon on "The Municipal Hospital in Germany," Prof. Dr. W. Pfeiffer (Essen), Dr. Med. Adolf Gottstein (Charlottenburg), Prof. Dr. Grober (Jena), Dr. Christopher Addison, M.P., Sir Henry Burdett, K.C.B., Mr. C. A. Parker, and Mr. W. P. Wright.

SECTION OF MEDICINE.

A discussion was opened on the first day on "Non-Diabetic Glycosuria," by Dr. A. E. Garrod, F.R.S., who pointed out that the tendency of modern research was to strengthen the belief in the internal secretion of the pancreas as being the chief factor in the control of carbohydrate metabolism. He was followed by Drs. Robert Hutchison, Aldren Turner, P. J. Cammidge, J. F. Gordon Dill (Hove), W. Essex Wynter, E. W. Blackburn, and the President, Dr. E. Hobhouse (Hove). On the second day, Dr. A. P. Luff opened a discussion on "Fibrositis and Muscular Rheumatism," followed by Drs. F. H. Humphries, A. Morison, C. F. Bailey (Brighton), W. M. Crofton (Dublin), Preston King (Bath), Marion Gilchrist (Glasgow), George Parker (Bristol), A. A. Warden (Paris), and W. Langdon Brown. The last day was occupied by the reading of a paper by Dr. Murdoch MacKinnon (London) on "Arterial Pressure in Thoracic Aneurysm," and Dr. Walter Broadbent (Brighton) contributed a paper on "The Heart as Affected by the Stomach," while Dr. Preston King read a paper on "Differentiation in Chronic Joint Affections."

SECTION OF NAVY, ARMY, AND AMBULANCE.

The President, Col. J. Turton, V.D., F.R.C.S. (Brighton), gave first a short account of the relation existing between the Voluntary Aid Detachments and the medical organisation of the Territorial Force. Major Birrell, R.A.M.C., then read a paper on "Notes on the Work of a British Red Cross Unit with the Bulgarians." Lieut.-Col. Donegan described the relation and utility of the various types of aeroplanes in connection with medical service in the field. On the Thursday, Dr. Louis Durey, French Army Service, read a paper on "The Use of Kinesitherapy in the After Treatment of Injuries Received in War." Other papers were those by Lieut. D. G. Kennard, R.A.M.C. (T.F.) on "A Proposed Light Ambulance for Yeomanry Regiments," and by Major J. W. Houghton, R.A.M.C., on "Spinal Analgesia in Military Service."

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

On the Wednesday, Sir George Savage opened a discussion on "Sleep and the Treatment of Sleeplessness," in which Drs. W. H. Butler Stoddart, C. Hubert Bond, Constance E. Long, J. R. Lord, and D. G. Thompson took part. The next day was occupied in a discussion on "The Significance and Treatment of Vertigo," which was opened by Dr. J. S. Risien Russell, followed by Drs. Broadbury (Cambridge), H. Campbell, Prof. E. D. Fisher (New York), Helen Boyle (Brighton), L. Guthrie, A. Mackintosh, Aldren Turner, C. Russell, T. Williams, and others. On the Friday, Dr. Tom Williams (Washington) read the first paper on "Some Truths and Fallacies about Mental Healing," followed by Dr. R. J. Anderson on "Some Aspects of Reflex Action in Man and the Lower Animals." Dr. M. D. Eder dealt with "The Present Position of Psycho-analysis," while Dr. Hugh Wingfield spoke on "Suggestion in the Treatment of Alcoholism."

SECTION OF OPHTHALMOLOGY.

On the first day Mr. J. Hern (Darlington) read a paper on "School Clinics and the Prevention of Myopia." He was followed by Mr. A. F. MacCallan (Cairo) on "Ophthalmic School Clinics in Egypt," and in the discussion which followed, Dr. E. Maddox (Bournemouth), Dr. T. Harrison Butler (Coventry), Dr. J. A. Wilson (Glasgow), Mr. N. Bishop Harman (London), Prof. T. E. Weeks (New York), Prof. R. A. Reeve (Toronto), Mr. J. H. Parsons (London), Lieut.-Col. R. H. Elliot, I.M.S., Dr. W. B. Inglis Pollock (Glasgow) took part. Other papers followed by Dr. Maddox and Dr. T. A. Wilson. On the Thursday, a discussion was opened by Dr. T. Harrison Butler on "The Treatment of Chronic Dacryocystitis." Dr. F. W. Edridge-Green (London) read a paper on "A Criticism of the Board of Trade Eyesight Tests," and moved a resolution, "That the sight tests of the Board of Trade are not satisfactory, and that an inquiry is urgently needed in the interests of the mercantile marine and of the nation." This was seconded by Mr. Devereux Marshall, and carried with one dissentient. Dr. Inglis Pollock followed with a paper on "The Persistence of the Nerve Plexus of the Iris after Excision of the Ciliary Ganglion and of the Superior Cervical Ganglion." The last day was occupied with a discussion on the question of "Excision in Cases of Injury to the Eye," by Mr. M. L. Hepburn (London) followed by Mr. R. Affleck Greeves, Mr. Bishop Harman, Dr. Maddox, and others. Mr. S. H. Browning (London) read a paper on "The Blood Conditions in Sympathetic Disease." Other papers by Drs. MacCallan and Harrison Butler concluded the work of the section.

SECTION OF PHARMACOLOGY, THERAPEUTICS, AND DIETETICS.

The proceedings opened with a paper by Dr. H. Gray Barbour (University of Yale) on "The Pharmacology of Body Temperature." A discussion then followed on "Urinary Antiseptics," introduced by Mr. J. W. Thompson-Walker (London), followed by

Prof. Bradbury and Mr. A. R. Jordan. On the Thursday, there was a discussion on "Anaphylaxis," opened by Prof. W. E. Dixon, which was held conjointly with the Section of Bacteriology and Pathology. Dr. F. W. Pierce read a paper on "A Further Investigation of the Action of Digitalis on the Blood Pressure in Man." On the last day, Dr. H. F. Winslow read a paper on "Some Errors in Dietetics." A discussion ensued on "The Use and Abuse of Hypnotics," introduced by Dr. W. H. Willcox, followed by Dr. M. Craig, Gray Barbour, and Dr. J. C. Uhthoff (Hove). Other papers followed by Dr. A. Haig and Dr. C. Mathu.

Section of State Medicine.

Dr. H. O. West (Maidstone) opened a discussion on "The Prevention and Treatment of Tuberculosis," followed by Drs. A. Serrell Cooke, Duncan Forbes (M.O.H., Brighton), J. MacKeith, R. Murray Leslie, A. Griffith, W. A. Bond, W. Ewart, and J. C. McWalter (Dublin). The resolution was passed:—"That this Section of State Medicine recommends to the Council of the British Medical Association that representation should be made to the Government that in cases of tuberculosis receiving sanatorium benefit, the sickness benefit provided should not lapse at the end of six months, but should continue so long as the patient is, in the opinion of the medical adviser to the Insurance Committee, unfit for work." On the Thursday, Dr. Herbert Williams (M.O.H., Port of London) introduced a discussion on "Port Sanitary Administration, More Especially with a View to the Prevention of the Introduction of Diseases." He was followed by Major R. W. H. Jackson, R.A.M.C., Dr. F. A. Foy (Rangoon), and Mr. Gilbert E. Brooke (Singapore). Dr. Foy then read a paper on "Deratisation in the Port of Rangoon." The last day was occupied by a discussion on "The Need for Popular Education in Matters Affecting the Public Health," introduced by the President, Dr. E. W. Hope (Liverpool), followed by Prof. H. R. Kenwood (London), Dr. T. A. Williams (Washington), Dr. R. Murray Leslie (London), Dr. Wynne (Wigan), and Dr. J. C. McWalter (London). On the motion of Dr. Hope, seconded by Dr. Murray Leslie, the following resolution was unanimously adopted:—"That a recommendation be forwarded to the Council of the B.M.A., endorsing the views expressed in the circular letter recently issued to the metropolitan public Press by recognised leaders of the medical profession in regard to the question of venereal disease, and strongly recommending the appointment of a Royal Commission to inquire into this subject, which so closely affects the public health."

Section of Surgery.

A discussion was opened on the Wednesday, by Mr. G. H. Makins (London) on "The Diagnosis and Treatment of Carcinoma of the Stomach," followed by Mr. E. W. Hey Groves (Bristol), Dr. T. R. Dalziel (Glasgow), Mr. A. H. Buck (Brighton), Mr. W. McAdam Eccles (London), and Mr. H. B. Robinson (London). Mr. D. P. D. Wilkie read a paper on "Experimental Observations on the Cause of Death in Acute Intestinal Obstruction." A paper was also contributed by Dr. A. A. Warden (Paris) on "Radium and Inoperable Cancer." On the Thursday, a discussion on "The Diagnosis and Treatment of Injuries of the Knee-Joint Other than Fractures and Dislocations" was introduced by Mr. A. M. Martin (Newcastle-on-Tyne), in which Messrs. A. J. Walton (London), R. H. A. Whitlocke (Oxford), Hey Groves, Dalziel, E. F. Finch (Sheffield), J. M. Cotterill (Edinburgh), McAdam Eccles, A. C. T. Woodward (London), and the President, Mr. W. Thelwall Thomas, F.R.C.S. (Liverpool) took part. Mr. Hey Groves read a paper on "The Operative Treatment of Compound and Comminuted Fractures," and Dr. Dalziel contributed one on "Chronic Enteritis." The last day was occupied with papers by Mr. H. Wade (Edinburgh), on "Prostatism, the Pathological Basis of the Operative Treatment"; by Dr. Dalziel, on "Neuralgia of the Twelfth Dorsal Nerve Simulating Visceral Lesions"; by Mr. Herbert J. Paterson (London) on "The Surgical Treatment of Intestinal Stasis"; and by Mr. C. P. Childe (Southsea) on "A Case of Retroperitoneal Fibroma, 34¾ lbs. in weight, Successfully Removed."

Section of Tropical Medicine.

The proceedings opened by a discussion on "The Causes of Invaliding in the Tropics," introduced by Dr. G. Basil Price (London) who had made a statistical investigation into the subject. He was followed by Col. R. J. S. Simpson, A.M.S. (ret.), Dr. W. F. Law (British Guiana), Dr. C. F. Harford (Livingstone College, Leyton), Dr. G. Duncan Whyte (Swatow), Major W. S. Harrison, R.A.M.C. (London), Dr. Malcolm Watson (Federated Malay States), and Dr. M. Cameron Blair (Northern Nigeria). Mr. J. Cantlie (London) described "A Series of Observations on Sprue." On the Thursday, several important and interesting papers were read on "Dysentery," the subject being introduced by Capt. S. R. Douglas, I.M.S. (ret.), followed by Messrs. J. Graham Willmore and H. Savage (Egypt) on "The Effects of the Serum Treatment of the Bacillary Form of the Disease." Dr. C. M. Wenyon (London School of Tropical Medicine) described "The Morphology of the Intestinal Amœbæ." After a discussion thereupon, in which many members took part, the Section adjourned to the Museum, where Prof. v. Wasielewski, of Heidelberg, demonstrated the various types of the organism. On the Friday, a discussion on "Filariasis" was opened by Dr. G. C. Low, of the Tropical Diseases Bureau, London, and Dr. Bahr demonstrated filaria in the Museum. Lieut.-Col. Cecil Birt, R.A.M.C., read a paper on "Dengue and Phlebotomus Fever."

(*To be concluded.*)

INTERNATIONAL MEDICAL CONGRESS.

THE HISTORICAL MEDICAL MUSEUM.

FIRST NOTICE.

One of the most interesting features of the International Congress of Medicine will be the Historical Medical Museum, organised by Mr. Henry S. Wellcome. The collection he has brought together is officially connected with the Congress Section of the History of Medicine. Situated in spacious quarters in Wigmore Street, it presents a veritable mine of interest for all philosophic students of the past, but more especially for those who are also members of the medical profession. Entering the turnstile one sees on the left the model of a floating laboratory, auxiliary to the Wellcome Tropical Research Laboratory at Khartoum. This boat travels up and down the Nile; it draws very little water and is fitted up for medical scientific research work. This model forms an apt threshold—as it were—to the main hall of primitive medicine. Here are medicine men's costumes from various countries—such as Uganda, the Upper Congo region and South Africa. A striking object in one corner is a full-sized model of a medicine man's hut in New Guinea. Perched on timber posts some 8 ft. from the ground, it is built on the plan common to the elevated dwellings of primitive mankind, and is in all probability handed on from the architecture of the early lake-dwellers.

The frieze of the hall is formed by masks of the savage medicine men and the "Devil Dancers of Ceylon." These are used as a scheme of decoration together with the skins of wild beasts. A most grotesque object is the Maori Talisman of Life and Death, a squat figure carved in wood—giving one the general impression of a cretin. On the walls are portraits, maps, diagrams, documents and pictures illustrating the past history and present knowledge of plague, malaria, yellow fever, and other tropical diseases. It is obviously impossible within the necessarily scanty limits of a descriptive report like the present to note adequately the many objects of interest contained in this and other parts of the Museum, but an outline of some of its chief attractions may be of some service to the intending visitor.

Near the main entrance is to be found a series of specimens showing various pathological conditions among human remains unearthed from a prehistoric Ethiopean cemetery at Gebel Moya, Sudan. It is still being excavated by an expedition under the direction of Mr. Wellcome. There are photographs showing primitive methods of sepulture. Some of the bodies are buried face downwards, some crouched, and so on. The skulls are prognathous, and the whole exhibit opens up a field of entrancing and notable interest to the ethnologist. One reconstructed grave shows some large gall-stones which were actually found *in situ.* There is also the skeleton of a young man, over 6 ft. in height—a point of much interest in connection with this prehistoric race, of which literally nothing is known further than can be inferred from these relics.

One walks from the main hall into an annexe of parasitology. Much of Dr. Sambon's valuable and original work on pellagra is here set forth. There is a full collection of drawings and diagrams of the various insect carriers of disease—illustrating the various stages and anatomy. There are also a number of microscopic slides showing the more important protozoal agents of disease. Ranged amongst these specimens are many interesting fetish heads, and other objects connected with savage medicine. One especially interesting exhibit is a curved black wood bowl about the size of an ordinary wash-hand basin. It is elaborately carved and fitted with a curved handle. This bowl is used by the Maori midwives to receive the child after birth, and is regarded as sacred. It is inlaid sparsely with mother-o'-pearl and carved with symbolic figures, and forms a beautiful, and so far as we know a unique example of art in a primitive race.

One next passes through a corridor lined with water colours and oil paintings. Amongst them is a large oil painting of Dr. Dee the astrologer demonstrating before Queen Elizabeth and her Court at his house in Mortlake. This is a fine painting by Glendoni, and was exhibited at the Royal Academy some twenty years ago. Another interesting painting shows the house of John and William Hunter; it was lent by the Faculty of Physicians of Glasgow.

From the corridor one walks into a large hall of statuary. The room is called the Hall of Statuary, in which is grouped the statues and other illustrative sculptures connected with the art of healing, with a gallery above. In the centre is the model of a Greek temple, containing a collection of terra cotta votive offerings, some of them taken from the bed of the River Tiber. There are a number of early surgical instruments arranged in cases—some Græco-Roman, some Egyptian, some Chinese and others African. All these are well worthy of careful note by anyone interested in the development of the art of surgery. There are some fine reproductions of statues of Apollo, Æsculapius, Hygeia, Cheiron, and the Egyptian god Ptah. A curiously quaint figure is that of Ixtlilton, the ancient Mexican diety of healing, Shen-nung, the Chinese founder of medicine, dating about 3000 B.C. As illustrating the thoroughness with which the museum has been organised, it may be remarked that many of these statues have been expressly modelled by a sculptor from authentic sources, including Ea, the earliest known Chaldean diety, and Dhanwantari, the Vedic Father of Medicine. A striking figure is that of Marduk, a Chaldean and Babylonian deity. Next comes Adapa, the Sumerian genius of healing. These three figures reach back as far as the recorded history of medicine can be traced. The date of Ea was about 5000 B.C., and the others somewhat later.

Returning to the cases ranged beneath the gallery, it may be noted that the general idea is to illustrate the evolution of the instruments which have always been found essential by all surgeons throughout the ages—as, for instance, the lancet, the speculum, midwifery forceps, the traction hook, and the enema. The lancet traced out in this way is shown in its earliest form as a pointed finger-nail, which the Babylonian priest-physician allowed to grow long so as to serve him for surgical purposes. Amongst savage races a similar use of the finger-nail persists to the present day. Native surgeons in the Pacific Islands used sharpened shells, and a flint knife is shown, used by the Aborigines of Australia. In New Guinea, the medicine man uses a sharpened tooth fastened to a stick. Certain natives of Central America substitute the pointed spine of the agave. A beautiful specimen is the flaked obsidian knife still used by the medicine men of Java. Next comes the early Roman lancet of bronze, the primitive-looking lancet used to this day by the Hindoo surgeons, and lastly the bleeding lance of more recent times.

A number of dental instruments are shown. One of the earliest extracting appliances is the "Pelican," a grim, business-looking implement on the lever principle, dating from the seventeenth century, and being the direct progenitor of the modern "Rey."

An exceedingly interesting dental exhibit is the model of an Etruscan gold denture dating from about 3000 B.C. Two excellently shaped upper central incisors, carved from a single ox tooth, are held in position by a narrow horizontal band of gold fastened at each end to existing teeth. This is nothing more nor less than a fine specimen of that self-same bridge work which most people would unhesitatingly ascribe to the genius of modern invention. The evolution of the tooth-brush is shown in an adjoining case; amongst the specimen brushes being the first tooth-brushes made for King George III., stamped with the Royal Arms.

The gallery is literally crammed with objects of interest, the mere recounting of which would take up several columns of this journal.

It would therefore be impossible to describe or even mention everything in detail. Everyone, however, will gaze with interest on the contents of the large case at the north end of the gallery, containing as it does a collection of the original apparatus used by Galvani, the father of electricity. Some enthusiasts would regard this exhibit as one of the finest in the collection, but no visitor need doubt that he will find something after his own heart in this marvellously complete museum.

The gallery also contains an evolutionary collection of microscopes, in number nearly 200. The earliest dates from the famous Leuwenhoek (a model) and the latest from the middle of the nineteenth century. The early surgical instruments in cases ranged along the west wall are of unique interest. They comprise amputation and trepanning sets, lithotomy instruments and various progressive patterns of the official outfits required by military and naval surgeons in ancient times. There is a large and valuable collection of charms, amulets and talismans of ancient and primitive peoples, besides many latter-day specimens from European countries. The Egyptian collection is specially fine and contains many specimens that are not to be found in the large museums.

In concluding this first notice it may be described generally as the finest collection of the kind ever brought together, and we again venture to express a hope that it may become the nucleus of a national medical museum. The whole of this collection has been studied and arranged with indefatigable zeal by Mr. C. J. S. Thompson, who has been engaged in historical medical research for a number of years. To his courteous and skilled information we are indebted for many of the facts on which this descriptive article is based.

Medical men may perhaps be reminded that no special invitation is necessary to enable them to visit 54A, Wigmore Street, Cavendish Square, London, W. As a matter of fact admission is at once obtainable by any medical man on presentation of a visiting card.

Permission has been given to Mr. Sydney Gaster, M.R.C.S., L.R.C.P., and Mr. Henry White, M.R.C.S., L.R.C.P., missionaries of the C.M.S., to perform the duties of Diocesan Readers in the London diocese during their present furlough.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, Aug. 2nd, 1913.

At the meeting of the Gesellschaft für Chirurgie, Hr. Jacquin read a paper on

Arrest of Hæmorrhage from the Liver by Pedunculated and Free Flaps of Omentum.

He said the usual methods of arresting hæmorrhage from the liver were by ligature, suture, and tampons. The arrest of hæmorrhage was frequently attended by considerable difficulties. Suture often failed from the tissues being too soft, from the bleeding spot being badly situated as regarded accessibility, and finally, the condition of the patient did not admit of delay. Here tamponade was to be preferred. It was successful as regarded the arrest of the bleeding, but it had the disadvantage that the abdomen remained open and a large cicatrix was left. There was also the danger of secondary infection. At the suggestion of his chief, Geheimrath Körte, he had interested himself experimentally in the subject. He had resected portions of the liver in dogs; it was also to be borne in mind that the livers of dogs were very friable. He proceeded as follows: The left half of the liver was exposed, the lower part drawn down, and during manual pressure a part of the lobe was resected; a resected piece of omentum was then placed over the freshly-cut surface. Even up to one fourth of the liver there was no bleeding, and no death except one from peritonitis. The examination made after the animal was killed with chloroform showed no blood in the abdominal cavity, the flap of omentum had healed in nicely. (Preparation shown.) Half of the control animals in which the omentum was not sewn over the fresh cut of the liver died from hæmorrhage; there was profuse hæmorrhage into the peritoneal cavity. The action of the omentum was to be explained mechanically, possibly there was also a chemical action.

Hr. Körte said that after cholecystectomy he had tried to arrest the hæmorrhage by means of the omentum and had succeeded, so that tampons were not required. Experimentally, free flaps of omentum were stitched on, as the attachment had to be made all round and had to be very exact. In operations on the human subject, however, pedunculated flaps were to be preferred. Wounds of the spleen had been treated in the same way with a similar good result. Instead of omentum, strips of muscular tissue had been made use of as a means of arresting hæmorrhage from the liver. The use of the omentum was more simple and more suitable, it was more readily obtained, and also placed in position more readily.

At a meeting of the Society for Social Medicine and Hygiene, Hr. Ulrici opened a discussion on

Tuberculosis.

As far as regarded treatment, he said there were three ways in which this might be approached:—(1) By preventing infection in mass, and above all in children; (2) raising the power of resistance of the individual threatened; (3) the medicinal treatment of cases of commencing tuberculosis. Up to the present the last-named path was the one that was the most frequented. No doubt a great deal of good had been achieved in that way, but more in the way of individual treatment than as a social measure. The second route of treatment had also been travelled with good success, but in the direction of prophylaxis, which consisted in finding out such as were liable to contract the disease and the isolation of them, there was still much to be desired. The German Committee for Combatting Tuberculosis, the chief aim of which was the erection of sanatoriums, had widened their aims, and had provided stations for the care of early cases, and there were now 1,500 such stations in Germany, but so far, they had scarcely an official standing. Notification, compulsory examination of sputa, would do a good deal in the way of prevention of infant infection. The usual isolation of the patient in his own house did but very, very little. Considering the length of time in which the patient carried infection (put down by the speaker at four years), the stay in the curative institution was too short to prevent the spread of infection. The fatal cases that generally went into hospitals for five or six weeks had generally infected those about them. The only effective way was the strict isolation of the infected person in institutions selected by the stations, especially taking care to note as to whether children had been exposed to infection or not. The proposal he had made tentatively to house families in which there were tuberculous members was deserving of consideration. The insurance bodies of the Rhine province were striving to keep their tuberculous cases in institutions as long as possible. Hospitals for tuberculous patients with pensions had been called "Death Houses," and were a complete failure. A better and more frequented path was to treat patients for lengthened periods in curative institutions, where hopefulness, which only became extinguished very late in the disease, was encouraged by the sight of patients who were being benefited by the treatment. The expense, it was true, was enormous, but in view of the fact that in Germany 80,000 people were resident in asylums for the insane, was one that might well be faced.

AUSTRIA.

Vienna, Aug. 2nd, 1913.

Fatal Result of Injection of Salvarsan.

At the recent meeting of the Gesellschaft für Innere Medizin und Kinderheilkunde in Wien, a communication was made by Dr. K. Ullmann on the subject of salvarsan intoxication. The text was afforded by an account of the symptoms which he had himself observed in the course of a fatal case. The specially interesting clinical feature of its history was the fact that death occurred soon after the administration of the second injection of a normal dose of the remedy. Dr. Ullmann differentiated carefully between salvarsan intoxication and the normal clinical effects of its administration, and he emphatically expressed the conviction, gained by his own experience, that it is only by making this discrimination, and acting carefully and consistently on its indications that any practitioner can safely attain a sound opinion and safe guidance regarding the therapeutic value of this remedy, and the ability to foresee and avoid its toxic effects. The fundamental features of salvarsan-intoxication would, possibly at least, appear to be those of arsenical intoxication; nevertheless, it is decidely a mistake to regard its phenomena as purely and simply identical with, or wholly dependent on, the effects of arsenical poisoning. The distributive momentum, which Ehrlich has placed at the apical position of arsenical therapeusis, displays itself not exclusively in its great principal influence as an antiparasitic agent; it also manifests itself in the collateral toxic effects. The individual differences which are clinically displayed during the employment of the various preparations of salvarsan, and the various different effects of the administration of other organic arsenical therapeutic agents (atoxyl, arsophenilglyxin) bear very significant testimony to the specific effects, as well as mode of action, of salvarsan itself.

Dr. Löwy described the anatomical conditions that were discovered in the *post-mortem* examination of this case. Changes were found of which some had been of evidently acute nature, and others which must have run a chronic course. The acute were obvious on mere macroscopic examination as hæmorrhagic foci. Microscopic examination of these areas revealed multiple capillary hæmorrhages in the cerebral cortex and in the spinal marrow, especially in the central grey matter, which was throughout bestrewn with those focal extravations. The chronic morbid changes were in turn displayed in the thickened and infiltrated meninges, as also in the arteries and veins, in the coats of which extensive alterations had taken place. The arterial walls displayed extensive changes as the evident result of advanced endarteritis. The tunica intima was extensively affected by those changes, which had specially affected the elastica interna, the layers of the latter, which were obviously broken into fragments and split up into their superimposed composites. (Here a preparation was exhibited, and the structural changes referred to were demonstrated.) The coats of the veins had also undergone corresponding alterations; they were infiltrated and thickened.) But in addition to those morbid structural changes in the area vasculosa, there was supplementary evidence found in the brain substance of the prolonged advance of "chronic regressive" alterations, of which very convincing testimony was afforded by the presence of numerous corpora amylacea. The conclusion was accordingly suggestible, from the anatomical standpoint, that the very serious chronic morbid changes in the coats of the vessels, and the long-standing degenerative processes which had been progressing in the substance of the neural tissues in the depths of the brain, would account for the establishment of any effective pre-disposition to the development of the vascular lesions which had supervened upon the administration of the injection of salvarsan.

The Still-Chaufford Syndrome.

Dr. H. Pallitzer described cases of the Still-Chaufford syndrome complex. Of his three cases, two had reacted conspicuously to tuberculin—and, indeed much more energetically to bovine than to human tuberculin. The third manifested no very striking or significant reactionary phenomena. The symptomatic relations to tuberculosis which appeared to be presented by those cases are of a clinical aspect, which in many directions would seem fairly similar to those that have been pointed out by Poncet as characteristic of the mutual relationship of tuberculous rheumatism and inflammatory tuberculosis. But their substantial existence, and the significance of their presence when demonstrable, have by no means been definitely established up to the present. But inasmuch as both Still and Chaufford disclaim any such relationship with regard to the clinical syndrome with which their names have become specially associated, the above-named designation would seem expedient for the purpose of a temporary demarcation, at least. The presence of glandular swellings in cases of chronic rheumatism is probably much more frequent than our contemporary German medical literature would appear to indicate. They may be overlooked in many cases, just as in tumefaction of the spleen; this is specially true of enlarged axillary glands.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE CONTROL OF QUACKS.

To the Editor of The Medical Press and Circular.

Sir,—The leaderette in your issue of July 23rd on the subject of the control of quacks leads me to mention that I have recently met with a case where "the curses have come home to roost."

A quack, of a very malignant type, recently brought his wife to me with double glaucoma, so advanced as to be almost beyond recovery, even in the one eye that had not gone blind. Her husband told me he had cured her of lock-jaw and three cancers (one would have sufficed for most ordinary beings), and on my suggesting the consideration of an operation he emphatically negatived it entirely. I found out from his wife (the patient) that her husband had refused to allow her to see any medical man for the past two years, and she—although an active partner in his "practice"—had the feeling that a mistake had been made. This, when told to a friend, produced from him the history of one of his patients who could not see him on a certain day because she had to visit a "specialist" (!) who was treating her once a fortnight for a dislocated hip. This hip slipped out every 14th day, so it seemed, and she had to have it replaced and treated at the cost of two guineas. It rather spoilt the romance of the story when it was ascertained that she walked to the station, took a two hours journey, walked to the specialist, and returned in the same manner, and with no discomfort or pain going or returning. A lame leg would not impede a quack much, but we suspect complete blindness will; but, who knows, they might heal (?) by touch then.

I am, Sir, yours truly,
A. A. Bradburne.

Manchester.

ALCOHOLIC QUACK MEDICINES.

To the Editor of The Medical Press and Circular.

Sir,—I believe most practitioners will endorse "Temperance Reformer's" strictures on certain medicated wines, but that the medical profession order them extensively is, I think, a libel. It does not say much for the progress of education that people buy such wines when there are wine merchants of repute of whom they can obtain wines of a known quality, and the other ingredients supposed to be in medicated wines are much better taken separately. I must differ entirely from your correspondent when he states so definitely (Medical Press, July 16th, p. 72) "that in every case of disease of whatever origin, where the chief subjective symptom is depression, alcohol acts as a poison of the most pernicious character."

I have been treating cases of indigestion now for over a quarter of a century, in many cases the chief subjective symptom being depression. I have thought it advisable in such cases to prescribe alcohol, with very excellent results, and nothing of the nature of a poison has manifested itself. In my own case, suffering from great depression and indigestion after an attack of influenza, I entirely cured myself by taking one ounce and a half of old matured whiskey in water before dinner; I was then able to partake of the meal and digest it. This I did for a fortnight without any pernicious effect. Like all other poisons, the dose of alcohol should be carefully prescribed.

I am, Sir, yours truly,
Thomas Dutton, M.D.

A DOCTOR'S WIFE ON DRESS.

To the Editor of The Medical Press and Circular.

Sir,—The wife of an average struggling doctor in a northern factory town with a brood of children—but not too numerous for the philoprogenitive instincts of their parents—has few opportunities of getting a real holiday during the earlier years of her married life, very few opportunities of seeing anything of the world beyond the narrow horizon of her habitual environment. For the first time in perhaps twenty years I have gained a little freedom. I have been away for some weeks, and have still a few weeks to spend before the finish of my holiday. I have had some days in London, some in Paris, some in various well-known Swiss resorts, ending, so far, with this fashionable rendezvous, Pontresina. My impressions have been various, mostly pleasant, some delightful, some few disagreeable. Among the last is my impression with regard to the dress of Englishwomen of the day. There is evidently a large minority who are not the slaves of fashion, but the great majority are merely the servile followers of the horde of male and female milliners who invent and design the dress which most women in every country throughout what is called the civilised world essay to copy. In the case of our fellow countrywomen at the present day the result on the whole is anti-hygienic, immodest, and indecent. Except the Germans, Englishwomen are the worst dressed that I have encountered among the cosmopolitan crowds with which I have recently mixed. The vast majority of Frenchwomen know how to dress themselves individually—how to enhance what charms they may possess, how to veil defects or blemishes of face or figure that demand concealment. The average Englishwoman has no idea of this. She evidently accepts her outer clothing on the word of the shopkeeper that it is "the latest Paris fashion," puts on the garments blindly, and makes herself a caricature of what in other hands might have some artistic significance. The innocent English mother and her more innocent daughter seem mostly unaware that Paris fashions are to a large extent invented for the requirements of the demi-monde. They don't know that the trade which we in England call prostitution is in France distinguished by a variety of pet names suggestive of the tolerance, favour, or admiration in which it is held by vast sections of male, if not female, society; and these Englishwomen would be amazed to learn that the misuse of a certain kind of French fashions gives them an appearance such as French prostitutes, except perhaps the lower ranks of this profession, would be ashamed to display. In London streets I saw vast numbers of sweet-looking girls with innocence written on their faces garbed in the indecent fashion I describe. They swarmed on the Boulevards in Paris, they crowd the hotel I am now in, and filled those I stayed at on my way here. My attention to this matter was stimulated by the extremely clever article in the *Times* on "Dress and Undress" which I read in London when starting. It was followed by an equally clever correspondence. Some writers tried to prove that the progress towards nudity which they described was the result of deep psychological influences acting without the consciousness of the agents, the women; but none of these explained how the supposed influences of the British female mind had been first able to lead the imagination of French fashion-mongers in the direction it had taken. It seems a tremendous pity that the mass of Englishwomen cannot shake themselves free from the bondage they now submit to. The present fashions must tend to destroy modesty, whilst no clothing could be more unhealthy than the garments of the day. They clog and hamper all freedom of movement, and reduce the wearer to the level of a useless doll. Englishmen are the best dressed in the world; a little courage might place their womenkind in a similar position, able themselves to set the fashion to the whole female world willing to clothe themselves in a way in which simplicity, beauty, health and utility might all be combined.

I am, Sir, yours truly,

A Doctor's Wife.

REVIEWS OF BOOKS.

THE NAUHEIM TREATMENT OF HEART DISEASES (a).

We feel pleasure in welcoming the fourth edition of this useful little manual. A medical man who is previously unacquainted with the method of preparation and administration of Nauheim baths in circulatory and cardiac affections cannot fail to gain much useful and practical information by careful perusal of this compact little book. In addition Dr. Thorne Thorne has given a series of most excellent and clear photographic illustrations of the way in which the Schott exercises are performed. These exercises are recommended as being of great use as an adjunct to the baths, and may on occasion be very beneficial in cases where, for various reasons, it is not possible to give the baths. We cordially agree with Dr. Thorne Thorne that baths and exercises carefully given in the manner which he prescribes, having due regard for the precautions to be adopted, are highly to be recommended in suitable cases. The reader is referred to explicit statements on the part of the author as to the distinction to be drawn between those cases which can be restored to health for a long period or permanently cured and those cases in which marked benefit is uncertain or which are unsuited for treatment. Put shortly, it amounts to this, that advanced organic disease, whether valvular or muscular or those which manifest grave defects in the node, bundle or its branches, in which the recuperative powers have been undermined, are not likely to yield good results from this kind of treatment. Favourable cases, according to Dr. Thorne Thorne, are many and various, and making all allowances for the enthusiasm of the writer, we are inclined to admit that results justify, for the most part, the selection that he has made.

The line diagrams of cardiac dulness illustrating various clinical cases appear, however, somewhat weird, and the author does not state, so far as we can see, whether these are intended to give results of percussion or of X-Ray investigation. In any case we fail to see how the outline of the base of the heart can possibly be separated out from its junction with the great vessels. We must confess that we would rather see records taken in a more usual manner, each indicating the position of the apex beat and the exact amount of extension to left or right. The author's style is clear and readable, and we recommend those in search of information in concise form to consult this little book.

TREATMENT. (a)

It is with peculiar regret we come to the notice of these handsome volumes. The editors were two of the most gifted of American physicians, one of them long recognised as a leading teacher and thinker, the other giving promise of equal distinction. Both are gone from us, and the world of medicine is the poorer.

We are speaking descriptively in saying that this system of treatment is American. Out of the more than eighty contributors, only four are cis-Atlantic, viz., Sir Clifford Allbutt, Sir Lauder Brunton, the late Clinton Dent, and Sir Berkeley Moynihan. The remainder may be taken to be fairly representative of the best of American medicine, though, as is natural, names which convey little to us in these countries are found side by side with those that are familiar.

The work opens with a brief but philosophic essay by the senior editor on the Fundamental Principles of Therapeutics. "It goes without saying," he says, "that the essential of success in therapeutics is correct interpretation." And he has impressed this view on his contributors, so that article after article opens with a discussion on diagnosis. "The *indications* for treatment," he tells us again, "are based on: (1) The cause of the disease; (2) a true conception of the morbid process; (3) the result of the examination of all the organs of the body; (4) the symptoms; and (5) the facts derived from the family, the social, and the previous medical history." Following on this introduction, we have general discussions on the various methods of treatment, which take up some seven-eighths of the first volume. The remainder of the work deals with the various groups of diseases in sequence.

We turn with interest to the sections contributed by British authors, and we find with pleasure that to Sir Clifford Allbutt is allotted the discussion of Diseases of the Cardio-vascular System. Needless to say, he deals with the whole subject in his own clear, logical, and convincing way. He dislikes the word "compensation," because it suggests "some notion of intervention, of device prearranged by the agency of nature, as the 'motorist' provides a spare tire in his car," and he suggests "readjustment" as a better term, since the process is merely the continuance of the process by which equilibrium has developed and survived and maintains itself. By the way, we must sympathise with Sir Clifford Allbutt in having to look at his clear-cut prose disfigured by American spelling. "Iodid" and "marvelous" give us pause, but is it the English author or the American editor who is responsible for the strange word "practitious," which we do not remember to have seen before?

(a) "The 'Nauheim' Treatment of Diseases of the Heart and Circulation." By Leslie Thorne Thorne, M.D., etc. Fourth edition. Crown 8vo. Pp. viii. and 104. With 55 illustrations. London: Bailliere, Tindall and Cox. 1913. Price 3s. 6d. net.

(a) "A Handbook of Practical Treatment." By Many Writers. Edited by John H. Musser, M.D., LL.D., and A. O. J. Kelly, A.M., M.D. In Three Volumes, pp. 909, 865 and 1,095. Philadelphia: W. B. Saunders Company. 1911 and 1912. Price 75s. net.

If Sir Clifford Allbutt's contribution is characteristic, so is that of Sir Lauder Brunton. He is charged with the discussion of the General Principles of Drug Treatment. He starts with a caveat, "While the effect of faith is very great in influencing the action of drugs and of other means of cure, yet drugs themselves, when properly used, have an enormous power to cure and prevent disease." Sir Lauder Brunton has indeed a faith which is shared by few physicians nowadays. It is perhaps due to the subject rather than to the author that the article deals not so much with the cure or prevention of disease, as with the suppression of symptoms. Nevertheless, Sir Lauder Brunton fails to make it sufficiently explicit that this is the case. We are told, for example, of the pathology of headache that the pain is "due to what one might term a colic of the arteries in the head, there being peripheral contraction and central dilatation." The use of such drugs as antipyrin and phenacetin is advised, without a word of caution as to their dangers.

Dr. Hektoen's article on the General Principles of Serum Therapy, though excellent as a treatise on immunity, is a little disappointing from the point of view of the practitioner looking for help in actual treatment. The title also is misleading, since the article includes a brief and entirely inadequate description of vaccine treatment. The brevity of this description is not due to lack of space, since space is wasted in discussing the serum treatment of various conditions in which such treatment is useless. The article on Toxæmia, Septicæmia, and Pyæmia, by Drs. Pearce and Elting shows a similar neglect of modern work. "The progress already made in the treatment of acute infections by immune sera offers some support for the hope that eventually each form of toxemia or septicemia may be treated by a special antitoxic or bactericidal serum." It is much more than ten years since this could be said with truth; and, indeed, in the next sentence the authors state quite accurately that at present "successful serum treatment is practically limited to diphtheria."

One of the most comprehensive articles in the work is that on Tuberculosis, by Professor Otis. He gives full advice as to the hygienic and dietetic treatment, and treats in detail of open-air methods, whether practised at home or in a sanatorium. The article is exceptionally well illustrated with plans and photographs of shelters, sanatoria, and hospitals.

We regret that space prevents us dealing with more of the articles. Worthy of special perusal are those on Constipation, and on Diseases of the Bronchial Tubes, by Musser; and on Pneumonia, by Dr. H. A. Hare. As a whole we can confidently recommend the book as helpful and suggestive. No one who uses it intelligently can fail to benefit thereby.

Each volume is furnished with an excellent index, but it would have been more convenient had there been a fuller table of contents.

THE SUPRARENAL GLANDS. (*a*)

The fact is obvious that the present medical generation is gradually establishing another special claim on the admiring gratitude of scientific posterity. What we refer to is the gradual solution of the problems of those very enigmatical structures which were long known—almost exclusively, indeed—by the collective appellation of "ductless glands." One of the distinguishing features, by the way, of this rather mystical group of unexplained items of human anatomy was, of course, the fact that they collectively numbered *seven*—a coincidence which obviously connected them with the unattainable, in the days when astrology and occultism played the chief *role* in physiological function and clinical phenomenology. Even when Luschka brought up his small contributory reinforcements to swell the list—the *glandula coccygea* and *glandula intercarotidea*—they still reached but a significant number which was at least semi-sacred to science, if not so exactly to mysticism.

The first considerable rent in the investing screen was the result of Addison's observations on the disease with which the name of that distinguished clinical observer is inseparably—and most deservedly—connected. But even still the purview remained very limited, and awaited the stimulating effects of the curious *spermatic* experiments of Brown-Séquard, and the resurrectionary movements of *opotherapy*, and the remarkable results obtained by the employment of *adrenalin* and of *thyroidin*. The (consequent) general speculations on the presence and physiological uses of the "internal secretions" then came up to expand the field of scientific research; and the borderland fringe of quasi-metaphysical ratiocination, with its opportunities for the roping-in of scientific "claims." One of the results is that we are now happily faced with the preparation of a splendid series of text-books dealing with "Les Glandes à Sécrétion Interne," of which the present volume is a representative octavo; the text of which displays throughout the exquisite crystalline transparency that so happily characterises all the scientific literature prepared by high-class Gallic experts. The quantity of concentrated essence of the results of experimental research here contained would surely give anti-vivisectionists material for the application of what depth of thought they are apparently capable, and leave some baskets-full over. The suprarenal gland extends its functional roots further, both in the circumferential and downward vertical direction, than we had ever dreamed of till quite recently. Even sudden death has been proved a result of latent destructive lesions of the suprerénals. And, unhappily, we find that: *Les causes qui peuvent être incriminées dans l'apparition de cette insuffisance suraiguë sont quelquefois impossibles à déceler.* Thus we have before us a vast domain of untilled, and surely productive, virgin soil; while the inspiring question asked of the ambitious budding pathologist is: "Can ye labour lea, young man?"

THE FATAL ILLNESS OF NAPOLEON BONAPARTE. (*a*)

The velocity of production of Napoleonic literature seems to progress contrary to most physical procedures of centrifugal movement, in accordance with the *direct* "law of squares." No sign of flagging of interest in the record of the greatest of the world's conquerors, and one of the most startling of its psychological phenomena, appears to be suggested by even the suspicion of an approaching shadow, as the centenary anniversary of his final overthrow approaches within range of easy measurability. Indeed the mysterious influence of the *Vril* which radiated from the Corsican's magnetic personality during life still seems to keep the upper strata of the philosophic atmosphere of our twentieth-century civilisation all a-quiver with its inexplicable undulations. Few, indeed, of the questions that involve "the Napoleonic legend" would seem to have been finally answered; and the medical enigma appears to be the only possible or conceivable one which had not received the attentions of some volunteer Œdipus before the present year.

Dr. Chaplin has undertaken the fascinating task of throwing a new light on the pathological item in the biography of the hero of Austerlitz. The subject has, according to his own account, being engaging his special attention for a number of years. He seems to be quite satisfied with the result of his researches, an appreciation which we can by no means pretend to share. Of his two special discoveries in this connection, the first is that the fatal gastric cancer was preceded by a chronic ulcer—which is not at all unlikely, and cannot now be definitely proved or disproved; while the pre-existence of the latter is by no means incompatible with that of the endemic hepatitis diagnosed

---

(*a*) "Glands Surrenales et Organes Chromaffines." Par M. Lucien, et J. Parisot. Avec 100 figures dans le texte. Paris, Societe d'Editions Scientifiques et Medicales. F. Gittler, Directeur. 1913.

(*a*) "The Illness and Death of Napoleon Bonaparte (a Medical Criticism)." By Arnold Chaplin, M.D.Cantab., F.R.C.P. With three illustrations. London: Hirschfeld Brothers, Ltd. 1913.

by O'Meara, at a date at which cancer had assuredly not begun to develop. The second discovery announced by our author is that Napoleon was not epileptic; a view which we have no hesitation in declining to accept, in presence of the evidence to hand of contemporary belief. The fact that the question is *not* mentioned by his medical attendants—who assuredly knew of the popular rumour—is strongly *confirmatory* to the minds of some of us; no medical man wishes to discuss the phenomena of epilepsy in a favoured patient, for the benefit of the idly curious and profane; especially when the victim is one of cosmopolitan fame and hypnotic personal power.

Our author displays the very undesirable quality (in a clinical critic, especially) of frequently contradicting himself, and then making matters worse again by forgetting that he has done so! The subject of Napoleon was surely worthy of closer attention—the research of "many years" has, in the present instance, yielded but a very lean crop indeed. And medical men should be the last to slur over the memory of the man who, after a wealth of experience unparalleled in the history of the human race, referred in his last Will and Testament to Baron Larrey as *the best man he ever knew.*

LATERAL CURVATURE OF THE SPINE. (*a*)

During the past six years, considerable attention has been devoted to the interesting subject of spinal curvature. Much practical work has been done, and our knowledge of the causation of deformities of the spine and of their correction has been widely enlarged. The present volume, which is the second edition, marks the present attitude of mind of the author, in common with various American and German authorities quoted, towards lateral curvature. One could wish that the English school of thought and practice had been more adequately represented, for although the book is dedicated to Mr. Robert Jones, of Liverpool, there appears to be little mention of his teaching or of the observations of other British surgeons or school medical officers. Similarly, the valuable anatomico-physiological work of Keith on the influence of the erect position upon the vertebral column, and the work of Halls Dally upon the influence of deep and proper respiration in promoting well-balanced action of the thoracic and abdominal musculature which has the effect of maintaining a correct position of the spine, might with advantage be referred to, since, as the author himself admits, "the general grouping and arrangement of the muscles in their relation to the spine has an important practical bearing on scoliosis" (p. 9). Turning from prophylaxis to treatment, we are glad to see that a considerable portion of the book is devoted to this matter, and for purposes of discussion cases are divided into two main groups: (1) postural or functional, and (2) organic or structural. This, on the whole, strikes one as a useful division which lends itself well to a description which follows of gymnastic treatment, symmetrical and asymmetrical exercises, clearly illustrated by line diagrams, forcible correction, braces and corsets. The creeping exercises of Klapp, which of late have received more attention in this country, have a page and a half given to their description, but the important warning is not clearly enough insisted upon that these, as well as many of the other exercises mentioned, are in the majority of cases of little permanent value unless carefully supervised by the doctor at frequent intervals during the course of treatment. Stress is rightly laid on fixation of the pelvis during gymnastic exercises performed in the standing position without apparatus, and the occurrence of scoliosis during school life, especially its increase in the less severe forms during the later years of school, is referred to in a separate chapter. In the letterpress to fig. 83, "curve" should surely read "burn."

(*a*) "Lateral Curvature of the Spine and Round Shoulders." By Robert W. Lovett, M.D., Boston, Assistant Professor of Orthopædic Surgery, Harvard Medical School. Second edition, revised and enlarged, with 171 illustrations. London: Rebman, Ltd. 1912.

MEDICAL NEWS & PASS LISTS.

Royal College of Surgeons in Ireland.

At a special meeting of the President, Vice-President and Council, held on Thursday, the 31st ult., Mr. R. Dancer Purefoy, President, in the chair, Dr. Evelyn John Evatt was elected to the position of Professor of Anatomy in the Schools of Surgery.

Professor Evelyn John Evatt is the eldest son of Captain C. A. Evatt, late of H.M.S. *Cherub*, and of Mount Louise, Smithborough, Co. Monaghan. He is in his 45th year, having been born in March, 1868. His maternal grandmother was a scion of the family of Colclough, of Tintern Abbey, Co. Wexford. He spent many years of his life with his father in India.

On becoming a medical student he joined the schools of the Royal College of Surgeons in Ireland, in which he studied for four years. He then went to Newcastle-on-Tyne, where in 1900 he took the degrees of M.B. and Bachelor in Surgery of the University of Durham. In the same year he obtained the licence in Midwifery of the Rotunda Hospital, Dublin.

Immediately after obtaining his qualifications, Dr. Evatt was appointed Demonstrator of Anatomy at the University College, Cardiff, and there he worked for nine years, at first under Professor A. F. Dixon, of Trinity College, Dublin, afterwards under his successor in the Chair of Anatomy at Cardiff, Professor David Hepburn. In 1904 Dr. Evatt was appointed Lecturer in Applied Anatomy in University College, Cardiff. This post he resigned on being appointed, in 1909, Professor of Anatomy at the Manitoba Medical College, Winnipeg, Canada. In 1912 he was elected External Examiner in Zoology for the University of Manitoba.

From the foregoing it will be seen that Dr. Evatt has had a very distinguished scientific career, and is certain to prove a worthy successor of Alec Fraser, Daniel Cunningham and Alexander Macalister—to go no further back in the annals of the Schools of Surgery of the Royal College of Surgeons in Ireland.

Professor Evatt has already done much original work in anatomy and embryology. He is at present engaged in writing a text-book of "Descriptive Human Embryology" at the invitation of a firm of medical publishers. This will probably be published during the current year.

Dr. Evatt holds the rank of Major in the Royal Army Medical Corps (Territorials). He is therefore well qualified to take on the work connected with the College of Surgeons' Contingent of the Officers' Training Corps.

Early Books on Medicine.

The British Museum authorities, in connection with the International Congress of Medicine, are exhibiting in the King's Library a series of early manuscripts and books illustrating the history of medicine. Several interesting examples of the writings of the herbalists are shown. Attention is drawn by the exhibits to the curious practice followed shortly after the invention of printing of applying the process to earlier works, and not to those of contemporaries. There are several volumes dealing with the plague, one of them being entitled "a passing gode lityll boke necessarye and behouefull agenst the Pestilence." Perhaps the most curious of the exhibits, however, is the manuscript of a contract between Nicholas Alcok, citizen and barber surgeon of London, in the reign of Henry VIII., and Robert Morton, of High Holborn, in which Nicholas promises to treat Morton for the bite of a mad dog for the very considerable fee of five pounds sterling.

The Hospital Sunday Fund.

The Lord Mayor presided last week at the Mansion House over a meeting of the Council of the Metropolitan Hospital Sunday Fund, called to receive the report of the Committee of Distribution.

The report of the Committee stated that the total of the fund was £50,381. Two hundred and sixty-three institutions had applied to participate in the fund, being six more than in 1912. The Committee recommended the distribution of £59,134.

The Committee had determined the basis of award to St. George's Hospital, but they recommended that no order be made as to payment until they were satisfied that no payment was made from the general fund of the hospital to the medical school except for work done in the treatment of the patients. A similar course had been pursued in the case of the award to St. John's Hospital for Diseases of the Skin, payment being withheld pending the result of litigation which was still undecided.

Sir William Church, Bart., moved that the report be adopted and the awards paid with the exception of the two mentioned. He remarked that of the total of £59,381, £31,485 had been derived from church collections, which was somewhat less than in former years. Dividends on Mr. George Herring's bequest were £20,793.

The report was adopted.

Medical Treatment ot School Children.

At a meeting of the Surrey County Council last week the revised scheme for the medical treatment of school children in the county, which has received the approval of the Board of Education, was adopted, and it was decided that the following fees should be charged to parents:—(1) Operations for tonsils and adenoids, including the necessary medical supervision after the operation, 10s. per case; (2) prescription of spectacles, 2s. (a separate charge will be made for spectacles; the charge will be the cost price, which will probably vary from 1s. 9d. to 4s. a pair); (3) X-ray treatment of ringworm, 8s.; (4) ordinary treatment of ringworm, 2s.; (5) treatment of running ears, 2s.; (6) other minor ailments, 1s.; (7) dental treatment—extractions, 6d. for one tooth, 1s. for two teeth or more, gas 1s. 6d. extra, fillings 1s. 6d. The above fees include any necessary drugs and dressings.

It is intended that the above fees should be regarded as maximum charges, and that it should be open to Care Committees to recommend a reduction of the fee in individual cases. The following scale of annual payments has also been adopted:—1s. 6d. per annum for one child; 2s. 6d. for two children; 3s. for three or more children.

The Annual Conference of the National Association for the Prevention of Consumption.

The Prime Minister opened, on Monday last, at the Central Hall, Westminster, the fifth annual Tuberculosis Conference organised by the National Association for the Prevention of Consumption. Lord Balfour of Burleigh, Chairman of the National Association for the Prevention of Consumption, presided, and amongst those present were Lady Aberdeen, Mr. Burns (President of the Local Government Board), and Lord and Lady Glenconner. The great hall was crowded with delegates, many of whom came from Continental countries and America. The principal topic of discussion was the value of the tuberculin treatment, the first paper upon which was read by Dr. H. W. G. Mackenzie, followed by Professor Sims Woodhead (Cambridge) and Professor Dr. Sims Rabinowitsch-Kempner (Berlin), Dr. Nathan Raw (Liverpool), Sir James Kingston Fowler, Dr. W. C. White (Pittsburg), Dr. Halliday Sutherland, Sir Robert Philip (Edinburgh), and Professor Sir St. Clair Thompson.

Royal College of Physicians and Surgeons.

At the first Professional Examination of the Royal Colleges of Physicians and Surgeons, held on the 15th, 16th, 17th, 18th and 19th ult., the following candidates were approved in the subjects specified below, viz.:—

Chemistry and Physics.—Robert G. Addenbrooke, Gerald A. A. Bradnack, Charles H. Carroll, Nai Chena, John R. Cox, Allen R. Crane, Gerald H. Duffield, Frederick K. Escritt, Wyndham B. Farrington, Evelyn H. Johnson, Walter H. Maudling, Kevin R. O'Brien, Alfred Pain, Ronald E. Rampling, Florence M. Rhodes, Alan H. Richardson, Guy Rooker, Henry L. Slaughter, Robert M. Somerset, Stuart W. Southwood, J. A. Stephens, Thomas N. Strange, Abbass H. Talaat, John N. Terry, Graham McK. Thomas, Francis E. G. Watson, and Dudley F. Wilson.

Chemistry.—Harold C. Clifford-Smith, Horace S. Drabble, Robert Erskine-Gray, Frederick H. Hyland, Mahomid Ibrahim, Lillian Lowenstein, Ralph K. Marwood, Khurshedjee Jamsedjee Rustomjee, and Ahmad Hussein Samy.

Physics.—William B. S. Andrew, Jane Crawford, Bryan O. Dewes, Noel E. Fasken, Edward F. Gillett, Hussein Amin Hathout, Christopher H. Macklin, Hugh Morris-Jones, Percival Randall, Douglas R. Thomas, Ian Thomson, and Graham A. O. White.

Biology.—Robert G. Addenbrooke, Norman J. Ainsworth, Herbert C. Apperly, Harry Barlow, Oswald Bastable, Frank Blake, John R. Cox, Francis W. Crook, Edward F. Gillett, Philip Green, Frank J. Harrington, Mamtaz Wali Mahomed Hassanally, Austin G. Hewer, John R. Houghton, Thomas G. James, Mohamed Khalil, Lillian Lowenstein, Alfred Yaphet Massouda, Gordon Millar, John W. W. Newsome, Alfed Pain, Marcel L. Quinlivan-Bulger, Percival Randall, Florence M. Rhodes, Khurshedjee Jamsedjee Rustomjee, Henry M. Savery, John A. Stephens, Phyllis Stevens, Thomas N. Strange, Frank H. Stuttaford, Trevor F. Thomas, Frederic F. Wheeler, and Graham O. White.

Royal College of Surgeons of England.

At an ordinary meeting of the Council of the Royal College of Surgeons held last week, with Sir Rickman J. Godlee, President, in the chair, the following distinguished foreign and Colonial surgeons were elected Honorary Fellows of the College:—

A. F. von Eiselsberg, LL.D., M.D., Professor of Clinical Surgery at the University of Vienna; E. Fuchs, M.D., Professor Ophthalmology at the University of Vienna; H. Hartmann, M.D., Professor of Clinical Surgery at the University of Paris; T. Tuffier, Professor of Surgery at the University of Paris; A. Monprofit, M.D., Professor of Clinical Surgery at the School of Angers, University of Paris; Dr. A. Bier; Professor of Surgery at the University of Berlin; Professor Dr. Werner Korte, Director of the Surgical Division of the Urban Municipal Hospital, Berlin; Dr. R. Bastianelli, Professor of Clinical Surgery at the Royal University of Rome; J. Nicolaysen, M.D., Professor of Surgery at the Royal Fredericks University, Christiania; H. Cushing, M.D., LL.D., Professor of Surgery at Harvard University; F. D. Bird, M.B., M.S., Lecturer in Surgery at the University of Melbourne; J. B. Murphy, A. M., M.D., LL.D., Professor of Clinical Surgery at the North-Western University, Chicago; W. J. Mayo, A.M., M.D., LL.D., Surgeon at St. Mary's Hospital, Rochester, U.S.A.; George Washington Crile, M.A., M.D., Professor of Surgery, Western Reserve University, Cleveland, U.S.A.,; Francis John Shepherd, M.D., LL.D., Professor of Anatomy and operative Surgery, McGill University, Montreal.

The following candidates, having passed the required examinations and conformed to the by-laws, were admitted Members of the College:—G. W. M. Andrew, B.A., J. V. O. Andrew, B. W. Armstrong, Kathleen J. Armstrong, S. L. Baker, F. Balkwill, J. R. Barrough-Clough, Margaret M. Basden, E. J. Boyd, B.A., E. A. Brock, A. E. Brown, B.A., Winifred F. Buckley, C. F. Burton, E. R. Chambers, Nai Cheune, W. H. W. Cheyne, Irene N. Clough, D. M. Connan, H. W. Cooke, R. Creasy, H. E. Creswell, B.A., H. L. Cronk, B.A., J. M. Curé, M. Das, R. W. Davies, S. B. Depree, D. J. Evans, H. W. Evans, H. Gibson, A. L. P. Gould, B.A., M. Gross, E. C. Hanna, A. M. Humphry, A. E. W. Irdis, G. D. Jameson, R. O. H. Jones, J. W. Kemp, G. L. Keynes, B.A., R. H. Lucas, Jessie McDonald, Margaret J. McEnery, W. J. McKay, D. D. Malpas, R. V. Martin, C. F. Mayne, B.A., J. D. Mercer, A. V. Moberly, W. F. Morgan, F. H. Mosse, G. T. Mullally, W. L. New, H. J. Orr-Ewing, D. S. Page, B.A., A. E. Panter, B.A., M. W. Paterson, P. E. H. Patey, V. D. Phatak, E. Phillips, J. W. Pigeon, B.A., F. P. Pocock, R. F. Quinton, K. V. R. Rao, M. O. Raven, B.A., H. A. Richards, B.A., H. C. Rigg, F. C. Robbs, E. D. Scott, A. L. Shearwood, L. R. Shore, J. S. Sloper, W. S. Soden, B.A., Mildred B. Stogdon, A. W. Taves, E. S. Taylor, B.A., A. Tilbury, J. L. O. Tilley, T. B. Vaile, G. O'N. Waddington, T. Warrington, B.A., J. R. M. Whigham, W. C. Whitworth, H. A. Williams.

C. Glover, having passed the requirements of the dental and surgical sections of the Board of Examiners in Dental Surgery, was admitted a Licentiate.

Mr. A. Rendle Short, F.R.C.S., Assistant Surgeon to the Bristol Royal Infirmary, was elected a member of the Board of Examiners in Anatomy and Physiology for the Fellowship; and Mr. Norman G. Bennett, M.B., M.R.C.S., was elected a member of the Board of Examiners in Dental Surgery.

Royal College of Physicians of London.

At the ordinary quarterly *Comitia* of the Royal College of Physicians held last week, the President, Sir Thomas Barlow, being in the chair, the following Fellows of the College were appointed officers of the College for the ensuing collegiate year:—

Censors: Sir J. Kingston Fowler, K.C.V.O., M.D., W. Hale White, M.D., Howard H. Tooth, C.M.G., M.D., T. Dyke Acland, M.D.; Treasurer: Sir Dyce Duckworth; Emeritus Registrar, Edward Liveing, M.D.; Registrar: J. A. Ormerod M.D.; Harveian Librarian, Norman Moore, M.D.; Library Committee: H. D. Rolleston, M.D., L. G. Guthrie, M. D., H. M. Fletcher, M.D., R. H. P. Crawfurd, M.D.; Curators of the Museum: J. M. Bruce, M.D., S. J. Sharkey, M.D., F. W. Andrewes, M.D., and W. Hunter M.D.; Finance Committee: Dr. Donald Hood, C.V.O., M.D., H. W. G. Mackenzie, M.D., and Sir James Reid, K.C.V.O., M.D.

The following were elected Examiners for the Licence Diploma:—

Chemistry.—J. M. Thomson, F.R.S., H. C. H. Candy, B.Sc.

Physics.—H. S. Allen, D.Sc., F. Womack, B.Sc., M.D.

Pharmacy.—H. J. Campbell, M.D., R. B. Wild, M.D., R. H. Miller, M.D., A. R. Cushny, W. E. Dixon, M.D., F.R.S.

Anatomy.—W. Wright, F.R.C.S., L.R.C.P.

Physiology.—L. E. Hill, M.B., F.R.S., and J. Mellanby, M.D.

Medicine.—L. E. Shaw, M.D., H. W. G. Mackenzie, M.D., F. W. Mott, M.D., J. S. Bury, M.D., A. F. Voelcker, M.D., C. Ogle, M.D., R. H. P. Crawfurd, M.D., Sir Bertrand Dawson, K.C.V.O., M.D., W. J. Harris, M.D.; H. B. Shaw, M.D.

Midwifery.—C. M. Handfield-Jones, M.D., J. S. Fairbairn, M.B., H. Williamson, M.B., C. H. J. Lockyer, M.D., J. B. Hellier, M.D.

Public Health.—H. R. Kenwood, M.B., L. C. Parkes, M.D.

Tropical Medicine.—F. W. Andrews, M.D., and W. J. R. Simpson, C.M.G., M.D.

Murchison Scholarship.—F. de Havilland Hall, M.D., and H. D. Rolleston, M.D.

J. B. Christopherson, M.D.Camb., being resident in Khartoum, was admitted to the Fellowship in absentia. Dr. W. Aldren Turner will represent the College at the third International Congress on Neurology and Psychiatry to be held at Ghent from August 20th to 26th next.

On the recommendation of the Committee of Management, Sir W. Watson Cheyne, C.B., F.R.S., was appointed visitor to the examinations of the Egyptian School of Medicine. The following institutions were added to the list of institutions recognised by the Examining Board in England for instruction in chemistry and physics:—Bradford College, Berkshire; Victoria College, Jersey; Exeter School, Northampton, and County School, Northampton; and Taunton School.

NEW MEMBERS.

The following gentlemen, having passed the required examinations, were admitted members of the College:—Fleet-Surgeon E. Bassett Smith, C.B., L.R.C.P., and M.R.C.S.Middlesex, C. Clarke, M.D. Lond., L.R.C.P., and M.R.C.S., Bristol and Univ. Coll., Lond.; A. Davies, M.D.Lond., L.R.C.P. and M.R.C.S., Westm.; A. H. Gosse, M.B.Camb., L.R.C.P. and M.R.C.S., St. Mary's; A. B. Gunson, M.D.Edin.; A. A. Ismail, L.R.C.P., and M.R.C.S., Cairo; W. W. Jameson, M.D.Aberd.; J. S. Lukis, M.D.Lond., St. Barts.; C. H. G. Ramsbottom, M.D., Vict., Owen's Coll., Manchester.

NEW LICENTIATES.

Licences to practise physic were granted at this meeting to the same candidates, who were also admitted to membership of the Royal College of Surgeons, and whose names are given in another column, together with the following:—C. H. Gould, A. S. Phillips, D. V. Pickering, D. L. Spence.

DIPLOMAS IN PUBLIC HEALTH.

Diplomas in Public Health were granted jointly with the Royal College of Surgeons to the following:—E. M. Balthasar, L.R.C.P., M.R.C.S., A. F. Bell, M.B., B.S.Melb., W. Bethune, M.B, C.M.Edin., H. S. Blackmore, L.R.C.P., M.R.C.S., W. H. Butler, L.R.C.P., M.R.C.S., J. A. Delmege, L.R.C.P., M.R.C.S., H. S. Dube, L.M. and S.Punjaub, W. R. Dunstan, M.B.Lond., L.R.C.P., M.R.C.S., A. L. Dykes, M.D.Edin., R. P. Garrow, M.D.Aberd., A. Gaskell, F.R.C.S., L.R.C.P., S. E. Gill, M.D.Lond., L.R.C.P., M.R.C.S., C. L. Goode, M.B., B.S.Melb., C. S. V. R. Harwood, M.B., B.S.Lond., L.R.C.P., M.R.C.S., A. A. Ismail, L.R.C.P., M.R.C.S., R. G. Johnson, M.B.Lond., L.R.C.P., M.R.C.S., P. M. Keane, L.R.C.P.&S.I., G. A. Kempthorne, L.R.C.P., M.R.C.S., N. M. Leys, M.B., Ch.B.Glas., C. H. Lilley, M.B., Ch.B., J. A. S. Phillips, L.R.C.P. and S.Edin., L.F. and P.Glas., E. S. Phipson, M.B., B.S., Lond., L.R.C.P., M.R.C.S., T. W. W. Powell, Capt., I.M.S., L.R.C.P., M.R.C.S., *L. W. Pugh, M.B., Ch.B.Edin., B. Rai, L.M.S., S. Ram, M.B., H. G. Sherren, L.R.C.P., M.R.C.S., G. H. Stevenson, M.B., Ch.B.Edin, J. Taylor, M.D., Capt., I.M.S.

*Under the Medical Act, 1876.

St. Thomas's Hospital, London.

The following House Officers have been appointed:—

Casualty Officers and Resident Anæsthetists.—W. J. Hart, B.A., B.M., B.Ch.Oxon.; M. J. Petty, B.A.Cantab., M.R.C.S., L.R.C.P.; F. McG. Loughlane, M.R.C.S., L.R.C.P.; E. N. Butler, B.A.Cantab., M.R.C.S., L.R.C.P.; A. L. Sutcliffe, B.A., M.B., B.C.Cantab.; H. C. Attwood, B.A.Cantab, M.R.C.S., L.R.C.P.; W. B. Foley, M.B., B.S.Lond.; A. Viney, M.R.C.S., L.R.C.P.

Casualty Assistants.—E. L. K. Sargent, B.A., M.B., B.C.Cantab.; L. G. Bourdillon, M.R.C.S., L.R.C.P.

Resident House Physicians.—H. P. Dawson, B.A. Cantab., M.R.C.S., L.R.C.P.; E. Wordley, B.A., M.B., B.C.Cantab.; S. G. Askey, B.A.Cantab., M.R.C.S., L.R.C.P.; D. B. I. Hallett, M.A., M.B., B.Ch.Oxon.

Resident House Surgeons.—F. E. Daunt, M.B., B.S. Lond.; W. J. F. Symons, B.A., M.B., B.C.Cantab; P. G. Doyne, B.A.Oxon., M.R.C.S., L.R.C.P.; L. N. Reece, M.R.C.S., L.R.C.P.

House Surgeon to Block S.—P. H. Mitchiner, M.B., B.S.Lond., F.R.C.S.Eng.

Obstetric House Physicians.—A. R. Chavasse, B.M., B.Ch.Oxon.; F. J. Humphrys, M.B., B.S.Lond.

Ophthalmic House Surgeon.—G. N. Brandon, M.R.C.S., L.R.C.P.

University of Oxford.

The following candidates have satisfied the examiners for the Diploma in Ophthalmology:—Harriet R. D. Ford, David Horgan, Khursedji N. Karanjia, George C. L. Kerans, George H. Oliver, David D. Paton, and Alexander C. Reid.

University of Cambridge.

The following have passed Part II. of the examination for the Diploma in Psychological Medicine:—Emma Mary Johnstone and R. C. Monnington.

Society of Apothecaries of London.

The diploma of the Society has been granted to the following candidates, entitling them to practise Medicine, Surgery and Midwifery:—S. H. Andrews, G. E. Cuttle, H. E. B. Finlaison, A. Lowndes, and T. B. Paul.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial,* and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Contributors are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

Reprints.—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

L. S. A. (Worthing).—Many persons suffer from headaches caused by the strong scent of flowers, such as narcissi and hyacinths, but these effects are slight as compared with the actual dermatitis frequently produced in susceptible individuals by contact with certain plants, such as the *Rhus toxicodendron*, *R. vernicifera* and the *Primula obconica*.

Dr. S. B. (London, W.).—Striking proofs have been given in our own military service in India of the efficacy of antityphoid inoculation, and there seems good reason to hope that with the gradual disappearance of the prejudice against inoculation the medical authorities in that country will soon be able to congratulate themselves on results as favourable as those shown by recent returns of the U.S.A. army.

Dr. W. S. T. (Toronto).—It is believed by some authorities that radium emanation causes an increase in the excretion of urea up to 34 per cent., and uric acid up to 14 per cent.

Ubique.—Although syphilitic lesions are more promptly relieved by salvarsan than by mercury, the latter is considered an essential supplement to the treatment.

Scrutator.—It has been stated on the authority of Sir Almroth Wright, that the injection of anti-streptococcic and anti-staphylococcic vaccines in the early stages of variola will prevent the subsequent pus-infections, to which mainly the fatality of the disease is due. Some cases in which the treatment was adopted pursued so benign a course as scarcely to be distinguishable from varicella.

Dr. A. H. Thomes.—Rectal suppositories of adrenalin chloride have a useful effect in stimulating the bladder to expel the urine in cases of hypertrophy of the prostate.

Appointments.

Donaldson, Malcolm, M.B., B.C.Cantab., Demonstrator of Midwifery in the Medical School of St. Bartholomew's Hospital, the election dating from October, 1913.

Eccles, McAdam, M.C.Lond., F.R.C.S.Eng., Surgeon to the London Temperance Hospital.

Evans, Arthur Henry, M.S.Lond., F.R.C.S.Eng., Surgeon to the London Temperance Hospital.

Faill, Charles James Campbell, M.R.C.P.Edin., L.R.C.S.Edin., Tuberculosis Medical Officer for the City and County of Bristol.

French, J. Gay, M.B., M.S.Lond., F.R.C.S.Eng., Surgeon in Charge of the Throat, Nose, and Ear Department at the Royal Free Hospital.

Hepburn, M. L., M.D., B.S.Lond., F.R.C.S.Eng., Ophthalmic Surgeon to the Royal Free Hospital.

Higgins, T. Shadick, M.D.Lond., D.P.H.Camb., Medical Officer of Health of St. Pancras.

Hosford, John Stroud, M.R.C.S., L.R.C.P.Lond., Ophthalmic Surgeon to the London Temperance Hospital.

McClure, James, F.R.C.S.Eng., Surgeon to Out-patients at the London Temperance Hospital.

Miller, Charles Hewitt, M.D.Cantab., M.R.C.P.Lond., Assistant Physician to the London Hospital.

Paterson, H. J., M.C.Cantab., F.R.C.S.Eng., Surgeon to the London Temperance Hospital.

Payne, John Ernest, M.B., B.C.Cantab., F.R.C.S.Eng., Honorary Surgeon to the Torbay Hospital, Torquay.

Metcalfe, James, M.D., Medical Officer in charge of the X-ray Department of the German Hospital, London.

Vacancies.

Glasgow District Mental Hospital, Gartloch, near Glasgow.—Medical Officer (Junior). Salary £150 per annum, with board, lodging, and laundry. Applications to the Medical Superintendent, Gartloch, Gartcosh.

Ayrshire Sanatorium, New Cumnock.—Medical Assistant, as Assistant to the Resident Medical Officer. Salary £150 per annum, with board and rooms in the Sanatorium, etc. Applications to Mr. Robert Welsh, Solicitor, 42 Sandgate, Ayr.

Preston Royal Infirmary.—House Surgeon. Salary £100 per annum, with board, residence, and laundry. Applications to Mr. Walter Davies, Secretary, 5 Winckley Street, Preston.

Swansea General and Eye Hospital.—House Surgeon. Salary £100 per annum, with board, washing, and attendance. Applications to W. D. Hughes, Secretary.

North Riding Infirmary, Middlesbrough.—Senior House Surgeon. Salary £100 per annum, with board, residence, and laundry. Applications to Charles Postgate, Secretary-Superintendent.

Cumberland and Westmorland Asylum, Garlands, Carlisle.—Junior Assistant Medical Officer. Salary £180 per annum, with board, apartments, and washing. Applications to the Medical Superintendent, Garlands, Carlisle.

Bradford Royal Infirmary.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to J. J. Barron, Secretary-Superintendent.

Dewsbury and District General Infirmary.—House Surgeon. Salary £120 per annum, with board, residence, and laundry. Applications to Edward Hemingway, Secretary.

Park Hospital for Children, Hither Green, London, S.E.—Assistant Medical Officers (two). Salary £150 per annum, with board, lodging, and washing. Applications to the Clerk to the Metropolitan Asylums Board, Embankment, London, E.C.

City of Liverpool Infectious Diseases Hospital.—Assistant Resident Medical Officer. Salary £120 per annum, together with board, washing, and lodging at the Hospital. Applications to the Chairman of the Port Sanitary and Hospitals Committee, Town Clerk, Municipal Offices, Liverpool.

Births.

Dick.—On July 26th, at "Morven," Sevenoaks, the wife of R. J. Dick, M.D., of a son.

Dominy.—On July 31st, at Southampton, the wife of G. H. Dominy, M.R.C.S., of Milton Abbas, Dorset, of a son.

Gabb.—On July 31st, at 13 Cornwallis Gardens, Hastings, the wife of Harry Gabb, B.A, M.B., B.C., of a daughter.

Gray.—On July 25th, at Exmouth, to Dr. R. W. and Hilda Gray (nee Mummery)—a son.

Passmore.—On July 29th at "Carlton House," Burbage, the wife of Dr. J. E. Passmore, of a daughter.

Paul.—On July 26th, at Ardbeath, 31 Melrose Avenue, Wimbledon Park, the wife of William Paul, M.B., of a daughter.

Woodwark.—On July 31st, at 38 Queen Anne Street, Cavendish Square, W., to Dr. and Mrs. Stanley Woodwark—a son.

Marriages.

Park—Bevan.—On August 2nd, at St. Cuthbert's Church, Philbeach Gardens, Edwards A. Park, M.D., of Johns Hopkins University, Baltimore, to Agnes, only child of the late A. Rawlinson Bevan, Esq.

Scott Holmes—Willey.—On July 29th, at St. Mark's, Reigate, Basil Scott Holmes, B.A., Registrar of the Architectural Association, son of Chancellor Scott Holmes, Canon of Wells, to Barbara Jesse Willey, youngest daughter of Henry Willey, Esq., M.B., F.R.C.S., of Reigate, and granddaughter of J. Scott, Esq., late of Albyfield, Bickley.

Deaths.

Bentall.—On July 29th, at 13 Roe Lane, Southport, Basil William, the infant son of Dr. and Mrs. Bentall, aged 18 days.

Coxwell.—On August 1st, at Godalming suddenly, of meningitis following influenza, Laurence Blake, the youngest child of L. D. and C. F. Coxwell, M.D., of Dulwich, aged 14 years.

Hodgson.—On July 25th, at 166 Peckham Rye, Robert Hugh Hodgson, M.D., L.R.C.P.Edin., M.R.C.S.Eng., ex Vice-President British Gynæcological Society, son of the late Captain C. G. Hodgson, Grenadier Guards, and grandson of Field-Marshal Studholme Hodgson.

Hollingsworth.—On August 1st, at Findern Lodge, Spring Grove, Isleworth, Surgeon-General Thomas Smith Hollingsworth, A.M.D., aged 85.

Kempe.—On July 31st, John Arthur Kempe, F.R.C.S., Edgbaston, Birmingham, aged 62.

Robinson.—On July 28th, at Lydd, the result of an accident, John Charles Reynolds Robinson, M.R.C.S., L.R.C.P., Major R.A.M.C. (T.F.), attached to the 1st East Anglian Brigade, R.F.A., aged 42.

Russell.—On July 26th, in Dublin, Arthur Willoughby, retired, Fleet Surgeon, R.N., son of the late Lieut.-Col. Francis Russell, Madras Army.

Simpson.—On July 31st, at Thornton Heath, Robert Arthur Simpson, Surgeon, formerly of the Royal Navy, and of New South Wales, aged 60 years.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, AUGUST 13, 1913. No. 7.

NOTES AND COMMENTS.

Public Health and the Congress.

ONE of the most striking facts of twentieth-century civilisation is the position occupied by medicine as a factor in the State control of public health problems. It is true that medical representation in Parliament is numerically small, but, nevertheless, this little section is sufficiently great to exercise an important influence both in the framing and the administration of laws affecting the health of the nation. Never was any Government in such a receptive mood as the present one in this country is to-day, nor, indeed, have there been such urgent matters vitally affecting the national health discussed by such a representative meeting of the medical profession as the International Congress of Medicine which concluded its sessions yesterday afternoon. If evidence were needed as to the interest in preventive medicine taken by the Legislature, one has only to point to the National Health Insurance Act, now in working order, and to the activity shown by the State all over the country with regard to the treatment and prevention of tuberculosis. There yet remains one omission, and that a most important one. What has been aptly termed a "conspiracy of silence" as regards venereal diseases has at last been broken through by the publication a few weeks ago in two daily papers of a striking letter, signed by some forty well-known members of the medical profession, demanding the appointment of a Royal Commission to inquire into the best means for preventing and dealing with these diseases. This letter was endorsed at a meeting of the Representative Body of the British Medical Association at Brighton last month. The question of the State control of syphilis was discussed last Saturday at a joint meeting of the Sections of Dermatology and Syphilography and Forensic Medicine of the Congress.

The Suggested Royal Commission.

THE ravages of syphilis are well known to all medical men, and that it is the greater danger to the community because its existence is ignored is all the more reason why a Royal Commission on venereal disease should be speedily appointed by the Government. As the letter referred to above states, there are in London alone 40,000 new cases of the gravest forms of the disease every year, and in the United Kingdom as a whole 130,000 cases. For the sake of the public health it is high time that something were done to check the dire effects of venereal disease in both sexes by awakening the public conscience as to the terrible gravity of the present situation. There is nothing to be gained by preserving a mysterious silence any longer with regard to syphilis and allied diseases—in fact, the time is now peculiarly appropriate for facing the facts and bringing them prominently before the public. The profession has much cause for gratitude to the editors of the *Morning Post* and the *Pall Mall Gazette* for inserting the appeal, and now that a resolution was passed at the Congress urging the Governments of all countries there represented to institute a system of confidential notification of syphilis and to make adequate provision for the diagnosis and treatment of the disease, it is earnestly to be hoped that the suggestion as to the appointment of a Royal Commission, the members of which should include a substantial majority of medical men, may receive the most careful attention of the Legislature. At any rate, the profession of this country has done its duty by inducing the lay Press to drag the matter into the common light of day so that it can be fully discussed and an organised effort made to combat venereal diseases and to reduce the mortality directly attributable to them. From the point of view, too, of therapeutics, having regard to recent discoveries in syphilology, it becomes an absolute necessity to ensure that every infected person shall receive the treatment which modern medicine has found to be the most efficient. Then, and only then, shall we be able to congratulate ourselves upon one of the results of the 1913 International Congress of Medicine.

Transfer of Patients from General to Union Hospitals.

LAST week we gave some particulars of an attack on a Dublin Hospital for sending an applicant for admission to the Union Hospital instead of admitting him to its own wards. Some of the Guardians of the North Dublin Union, apparently not satisfied with the complete vindication of the medical staff of the Hospital, as a result of the inquest, are attempting to stir up public feeling again. As is customary in Dublin, during the summer some of the wards of Jervis Street Hospital were closed for cleaning purposes. It was necessary, therefore, to dispose of their occupants; those who were fit to go home were sent home, those who could not leave hospital were transferred to another ward, whilst in a few cases it was considered best to send the patients to the Union Hospital as they still required nourishment, if not some supervision. As it is obviously impossible to accommodate every patient in general hospitals till he dies or is perfectly recovered, such a redistribution of cases is a necessity. Moreover, even with all the wards open, the medical staff must send out the patients to whom hospital is least beneficial, in order to admit those for whom it is essential. It is very easy to imagine the conditions that would determine the turning away of a sick person for the benefit of an extremely urgent case. The case in point was stated by the Guardians to be one of pneumonia. But it appears that one of the Visiting Physicians gave his permission to the patient to leave hospital. Now, pneumonia as a word is a generic term, so it is very probable that the case was simply one of chronic bronchitis; in fact, the action of the doctors makes that practically certain. It seems to us that the Guardians of the North Dublin Union have misunderstood the action of the medical staff of Jervis Street Hospital, and that failing real ground for complaint they are raking up misinterpreted facts before the public. Are all sick persons to be kept in general hospitals for ever? Can any general hospital turn itself into a home for incurables? for that is the only way it can avoid sending out people who are ill.

LEADING ARTICLES.

THE SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

It is no exaggeration to say that the sessions of the Seventeenth International Congress of Medicine, both general and sectional, which terminated yesterday, have proved the most important of any medical gathering in the history of the present generation. Never before have there been assembled so many masters of modern medicine, men whose names are known and honoured wherever scientific medicine is practised. We have accorded our confrères from beyond the seas a real British welcome and they have placed before us the results of their original investigations in every department of medical science. Such an occasion as this demonstrates more forcibly than anything else the real catholicity of medicine, for, as Sir Edward Grey aptly remarked, in welcoming the Congress on behalf of His Majesty's Government, science, in the true sense of the word, is international; it may have controversies, but they are not national controversies. The official recognition accorded to the 1913 Congress is noteworthy in that an eloquent tribute was paid by Lord Morley at the Government banquet to the influence of medicine in the political and social field in the United Kingdom. That medicine is now regarded by the legislature as a practical and powerful force in the framing and administration of laws is certainly a striking sign of the times, and, seeing the important resolutions carried by close on 8,000 Congress members, the Governments of some thirty communities all over the world may well pause to consider their responsibilities in connection therewith. The first of these resolutions dealt with vivisection, and ran as follows: "That this section records its conviction that experiments on living animals have proved of the utmost service to medicine in the past and are indispensable to its future progress. That accordingly, while strongly deprecating the infliction of unnecessary pain, it is of opinion, alike in the interests of man and of animals, that every facility should be given to competent persons for the performance of such experiments under adequate supervision." Professor Harvey Cushing, who gave the Address in Surgery, pointed out in a spirited fashion the great alleviation of human suffering which has resulted from the practice of experimenting upon living animals. Another resolution was "That, sensible of the ravages wrought by syphilis in the health of the community, and deploring the inadequacy of existing facilities for checking its dissemination, the International Medical Congress calls upon the Governments of all the countries here represented—(1) To institute a system of confidential notification of the disease to a sanitary authority, wherever such notification does not already obtain. (2) To make systematic provision for the diagnosis and treatment of all cases of syphilis not otherwise provided for." Such a resolution, coming at a time when an inquiry has been demanded by some forty eminent members of the profession in this country to investigate the facts relating to venereal diseases and their prevention, cannot fail to produce a deep impression upon the Government. That twenty-three sections and three sub-sections were necessary to carry on the work of the 1913 Congress, as against fifteen in 1881, is an evidence of the growth of medicine within a single generation. In the President's Address, delivered by Sir Thomas Barlow, which will be found in full in another column, we have a succinct *résumé* of the progress of medical science since the last Congress, and we need only refer here to bacteriology, radiology, vaccino-therapy, and electro-therapeutics, not to mention the relations of medicine to public health, especially in connection with tropical diseases, to show what degree of expansion and specialisation has been reached during this period. But there remains with us always the question of prognosis in disease, and Professor Chauffard, whose thoughtful Address in Medicine we also publish, has shown that recent progress in pathology and therapeutics has considerably modified the prognosis of many disorders in a remarkably short time. The greatest impression left by the 1913 Congress will be, perhaps, the re-adjustment of many of our former conceptions, notably the changed attitude of the profession with regard to the relations between medicine and surgery, which can no longer be considered antagonistic, and also in respect to the influence of medicine upon the national health. Provided with such a powerful stimulus, it is earnestly to be hoped that the Government will feel its responsibility in connection with the memorable resolutions passed by the Congress and win for itself lasting fame by promptly acting thereupon.

IRELAND AND THE MEDICAL BENEFIT.

The Report of the Medical Benefit Inquiry Committee, issued last week, deals with only a small part of the subjects included in the terms of reference. Those terms had to do not only with the question of the extension of the medical benefit of the National Insurance Act to Ireland, but with the much larger question of the changes required in the present system of medical relief in the event of such extension. In other words, the committee was directed to deal with the entire question of medical poor law reform. This part of its duties has been altogether shirked by the majority of the committee, and is only referred to in allusive terms. Moreover, the committee has not even come to grips with the immediate question of the extension of the medical benefit. Recognising the complexity of the problem, it has only considered in any detail the question of the extension of the benefit to industrial areas, and it is worth noting that it received no evidence from any industrial areas outside the limits of the county boroughs, though the majority report proposes to deal with such areas. It must be said at once that both on public and on professional grounds the proposals of the majority of the committee must be met with determined opposition. The public grounds of opposition cannot be better stated than in the minority report of Dr. Stafford. Speaking of the suggestion made as to the question of administering the benefit, he says:—"The recommendation to place a weapon in the hands of the Insurance Committees or societies by which they might impose terms on certain doctors which the body of the medical profession after prolonged discussion has decided to be inadequate, is not, in my opinion, a suitable means of obtaining a satisfactory medical service for the insured." He proceeds to consider the report from a more purely professional point of view. The suggestions made in the majority report are much what we expected. The majority of the committee recommend that the same sum per head, *i.e.*, 8s. 6d., should be provided for the medical benefit as in Great Britain; that the money should be handed to the societies to make their own arrangements for providing medical attendance either for members and dependents or for members only, as they think fit; or failing such arrangements, to give other benefits to the value of the additional contributions; that these arrangements should cover the county boroughs and certain other undefined industrial areas. These recommendations require only to be stated to receive uncompromising opposition on the part of the medical profession. The majority of the committee, in fact, openly advocate the establishment of a "blackleg" service under the control of the societies. They recognise that the money is not sufficient to lead to an agreement with the profession as an organised body, and that, therefore, the Government is not in a position to promise a medical service of the kind required with the funds at its disposal. But, they add, "the societies can attack the problem in detail. An individual society can, if it fails to make terms with the profession as a whole, appoint its own medical officer." In other words, the societies can establish a "blackleg" service. We do not think that this is what the insured people of Ireland require. It is worth quoting Dr. Stafford's perfectly accurate statement of the reasons why the Conference between the friendly societies and the profession led to nothing:—"The failure to come to terms was, in my opinion, due to the fact that the societies demanded as a *sine qua non* the inclusion of the dependents, and they had not at their disposal sufficient money to pay the doctors reasonable remuneration for the extra work imposed upon them. If the societies had been content to proceed on the same lines as in England, Wales and Scotland, and had confined their proposal to insured persons only, there would have been no difficulty in arranging terms with the medical profession in Ireland." Our position is simple. We are willing to accept service on the same conditions as our brethren in Great Britain; we are not willing to do two and a half times as much work as our brethren in Great Britain for the same money; we are not willing to accept service under the societies. If the Government determine to carry out the recommendations of the majority of the committee, it may succeed in establishing a cheap and nasty medical service. It cannot be too strongly emphasised that the public will get exactly the sort of service it is willing to pay for, and when we speak of payment we mean not only the actual pecuniary remuneration, but the general conditions of service.

CURRENT TOPICS.

Cross Questions.

In these days when we must at least pretend to a pride in democracy, quantity usurps the power properly the prerogative of quality. If a thing obviously futile in the singular is repeated often enough it attains a practical importance that is not its intrinsic due. That is why we pay attention to the futile fulminations of the half-penny Press. The vitriolic vials of searing sarcasm are poured out on the Medical Congress. Penny-a-lining pundits propound portentous propositions and pause for a reply. The questions are lovely in their infantile ingenuousness. The omniscient scribe asks: "Can you cure a cold?" and "Can you prevent a child from having measles?" with an implied "num, expecting the answer 'no.'" Apart from the fact that an absolute affirmative would be an accurate answer to both these queries, the fact of asking them is an acknowledgment of the modern craze for results. "*Cui bono?*" is being everlastingly dinned into our ears. Results are reality, and methods only madness. If that is the way we are to be judged, Heaven help our judges. Men who have no thought for the morrow and no idea of an ideal are like Westinghouses on the wheel of progress. People may read their words, but the man who heeds them is like unto their perpetrator and a thing of no account.

Medical Examination of Workers.

We have repeatedly advocated the medical examination of all workers before they are accepted by employers. Freedom and justice are empty names when they apply only to one of two contracting parties. With the law as it stands at present the employer has no protection whilst the employee risks nothing and has everything to gain. Capital cannot exist apart from labour, nor can the converse obtain. It is a matter of great practical difficulty for the employer to prove that any indisposition of an employee does not arise from the work of the latter. When the workman dies the onus of proof as to cause of death lies chiefly with the employer. Nor is the present condition of affairs good from the employee's point of view and from that of public health, for it is to the workman's advantage to keep at work for a few months in order that he may be entitled to sickness and disablement benefit. It is obviously unwise to make it profitable for a sick man to work, if it can be prevented. If conscription has no other advantages it certainly has this, that every male undergoes medical examination and that an employer can choose sound men for his work. It is so obviously unscientific to determine the time of incidence of a complaint with no knowledge of the previous condition of the patient, that one wonders why general medical examination has not been introduced already. Of course, the amount of physical strength necessary varies with each trade, so no general standard of efficiency could be introduced, but there is nothing to prevent a girl with an ankylosed knee being an efficient typist. Medical examiners could be appointed for each type of employment, and one cannot imagine that the result could be anything but good.

The Modern Comprehension of Crime.

One of the most interesting discussions that took place at the Brighton meeting of the British Medical Association was that on crime and punishment in the Section of Medical Sociology. The shortest definition of crime was given by Dr. James Scott as "an offence against the social order." There is an analogy between crime and disease, for both are departures from the normal. The root of all crime, according to Dr. C. A. Mercier, is a determination to obtain gratification for oneself regardless of the cost to others. It is, therefore, quite logical to insist upon the suppression of crime, otherwise society would undergo destruction. Exactly how this suppression is to take place is, of course, a debatable point. Some mawkish sentimentalists would hob-nob with the criminal and tell him that he is not such a bad fellow after all, but is only an ill-used and misunderstood unfortunate. The real object of all punishment is ultimately preventive, being in the first place deterrent. In most countries there is a reaction against the older systems of harsh and almost vindictive punishment—in fact, it would seem as though there is a danger in some quarters of too much leniency being exercised, for prison existence is fast becoming transformed into something like hotel life. Be that as it may, it must be admitted that the Borstal institutions have effected considerable reform in our prison system. Another important change which has not been in operation for very long is the preventive detention of habitual criminals in special institutions. If there were greater agreement between the medical and legal professions, especially in regard to the question of criminal responsibility, it is possible that the punishment would be better suited to the crime than is sometimes the case at present.

Yellow *versus* White Vaseline.

When white or bleached vaseline was first introduced many years since, there was a great outcry on the part of surgeons and dermatologists against it on various grounds. The protest fell on deaf ears, and nowadays the "purified" product is almost exclusively employed in medicine. It may, however, turn out that the pale vaseline is, after all, less therapeutically active than the crude product. To begin with, it is highly probable that the process of bleaching leaves chemical oxidising agents therein, and in any event we have Dr. Carrel's word for it that yellow vaseline is much preferable to the white variety as a preservative of living tissues in a state of suspended animation. Its value resides in the fact that it effectually prevents clotting of the blood in the vessels, besides preventing desiccation. The efficacy of its action may be inferred from the fact that skin preserved in this way can be used for grafts with every prospect of success many weeks, if not months, after.

Opium in China.

A white paper has recently been issued by the Foreign Office containing reports by Sir J. Jordan, His Majesty's Minister at Peking, respecting the opium question in China. The first despatch is dated May 26th last, and contains reports of the general position in several of the Provinces. The Minister thinks that on the whole it may fairly be said that the Chinese Government have shown signs of earnestness in the suppression of opium cultivation in the Provinces this year, and an advance in this direction has been made within the last three months. While making full allowance for their difficulties, Sir J. Jordan remarks, however, that he cannot but point out that a great deal remains to be done before the work of suppression can be considered as complete—notably in the Provinces of Yünnan, Kueichow, Kiangsu, Kansu, and Szechuan. Writing again on the second of last month, Sir J. Jordan enclosed copies of reports on journeys recently completed in Anhui, Hunan and Shantung, with a view to ascertaining the extent of poppy cultivation still existing in those Provinces. The despatch states that five Consular officers were detached for the work, and, accompanied by Chinese delegates of the metropolitan and provincial governments, they conducted a searching inquiry into the conditions of cultivation, consumption, and traffic in native opium. Their investigations failed to reveal any poppy crops within the area under inspection, and the Minister has informed the Chinese Government that, in view of the effective suppression of the cultivation and import of the native drug, the conveyance of Indian opium into the Provinces of Anhui, Hunan, and Shantung will now cease, in accordance with the terms of Article 3 of the Agreement of 1911. It is pointed out that these are the first tours of the kind which have been carried out by British and Chinese officers working together, and Sir J. Jordan is of the opinion that the good spirit and fellowship with which they have been conducted under arduous and trying circumstances reflects much credit on all concerned.

The Olfactory Sense in Medicine.

Though it is true that the sense of smell is not so highly differentiated in man as in some of the lower animals, yet instances of olfactory keenness in the human subject are not so very uncommon. The connection of certain odours with normal or pathological conditions of the body affords a most interesting clinical study, and this association may be of some service in the diagnosis of disease. In a comprehensive article upon the subject in the *New York Medical Journal*, Dr. Robert E. Coughlin states that probably most physicians and nurses use the sense of smell either instinctively or as the result of experience in diagnosticating disease or appreciating morbid conditions. Because it is difficult to set up an exact scientific standard of odours little or no attempt has been made in medical text-books to give olfactory diagnosis its rightful place among clinical methods. No one will deny the value of the "mousy" odour in favus, for instance, or that of the odour of acetone in the breath of diabetics. Each secretion and excretion of the body has its own particular odour which may be greatly modified both in health and disease. Every medical man is familiar with the characteristic urinous odour in cases of incontinence of urine, with the horrible stench associated with mercurial gingivitis or a neglected pediculosis capitis. The worst smell of all is said to be that produced in cases of gangrene of the lung. Certain general diseases, such as phthisis, acute rheumatism, diphtheria, and typhoid fever, may frequently be distinguished by the presence of particular odours not met with in other affections. One very often finds that experienced nurses are able to diagnose these and other diseases from the sense of smell alone, and, likewise, they are sometimes able to presage the fatal termination of some severe malady from the peculiar odour given forth by the patient just before death. To untrained nostrils these subtleties do not appeal, nevertheless, there can be no doubt as to the value of the olfactory sense in prognosis as well as in the diagnosis of disease.

An Anti-Climax.

A man from Frankfort has been charged with three interesting murders. In his bright, scientific, German way he married three wives—not simultaneously, but in due sequence, each after the demise of her immediate predecessor. The police, whose suspicions were aroused by three coincidental corpses, searched the house and found pure cultures of cholera and typhoid of a specially savage brand obtained from the Bulgarian war, which had been got from Vienna by the simple expedient of writing on notepaper bearing the address of an imaginary scientific institution. "The best laid schemes . . . gang aft agley," and though the latest reports state that the man admits the administration of cholera and sausage, no untoward results occurred. The body of his first wife has been exhumed and found to contain large quantities of arsenic. Perhaps it is well that the inefficacy of bacteria orally administered should be extensively advertised. It will save a lot of trouble to individual criminals, and *Gott sei dankt*, will staunch the impending flood of detective stories that, built on this bacterial basis, imminently threaten us.

Ills that Flesh is Heir to.

There is a theory which looks at cancer as a dissociation of personality—a kind of cellular forgetfulness, an anarchy which looses the activity of cells from the control of the corpuscular community. The cells have forgotten their debt to the aggregate and, adopting an attitude of *sauve qui peut*, thrust themselves in a reckless rabble through the bounds of the basement membrane, unmindful of their duties as part of an organised entity, and only remembering the casual individuality of their ancestral amœbæ. It is a luminous way to look at cancer, and suggestions have been made to transfer the thought to many of the mental ills that now beset us. We are to hold that the defective mind is merely primitive—it can climb only the first few branches of its own genealogical tree, and, therefore, traits we thought psychopathic are really evidence of the persistence of primordiality. It is all very interesting and explains a whole lot of things, if we sit down and think about it. The so-called "migratory impulse in children" is a throwback to the nomadic shepherd and the flocks, "after which his soul longed and his feet tramped." Childish ills, too, may be the pestilential sufferings of a stone-age adult. Measles were likely the scourge of the pre-Adamites as well as the modern Melanesians, and non-notifiable ills that people expose their children to for the sake of getting them over were, without doubt, the paleolithic plagues of our semi-simian sires.

The Vivisection of Dogs.

In the discussion that has been going on in the lay Press on the subject of excluding dogs from vivisection it seems to be assumed on all hands that the suffering inflicted by an operation or consequent upon the injection of a virulent culture is something which would never have befallen the animal were it not for the remorseless vivisector. But Nature is far more remorseless, Nature knows no pity! The dog who has escaped the attentions of the inquisitive physiologist must sooner or later die of injury or disease, failing which death from inanition consequent upon senile decrepitude must be his lot. Only the favoured few can hope to end their days comfortably in the euthanasia chamber at the Dogs' Home. It follows that vivisectors do not add one item, however infinitesimal, to the sum total of canine suffering; on the contrary no unnecessary pain is inflicted in the laboratory, whereas Nature distributes it broadcast, gratuitously, cruelly. What does it matter to the dog whether its ephemeral existence is brought to an end by an experimental injection of the tubercle bacillus or by hydrophobia contracted as the result of unhygienic alimentary habits, by being run over by a motor-car, or by transplantation of its vena cava to a cat? The path and the goal are exactly the same, only the date and the object differ.

PERSONAL.

H.M. the King has been graciously pleased to sanction the following promotions in and appointments to the Order of the Hospital of St. John of Jerusalem in England:—To be Knight of Grace, Major Henry Brydges Yates, M.D. (from Esquire), and Lieut.-Colonel Sidney Monckton Copeman, F.R.S., M.D. (form Honorary Associate). To be Esquire, Major Francis Leonard Vaux, M.D., A M.C. (Canada), and Lieut.-Colonel John Taylor Fotheringham, M.D., A.M.C. (Canada).

Dr. W. Lindsay Locke, M.B., Ch.B.Edin., has been appointed Senior Medical Radiographer to Guy's Hospital.

Dr. John Parkinson, M.D., B.S.Lond., M.R.C.P. Lond., has been appointed Special Assistant to the Heart Department of the London Hospital.

Dr. James Metcalfe, M.D.Brux., L.R.C.P. and S.Edin., has been appointed Medical Officer in Charge of the X-ray Department of the German Hospital, London.

Mr. H. Hayward Bywater, M.D.Vict., F.R.C.S. Edin., D.Ch.O.Liverp., has been appointed Honorary Assistant Surgeon to the Liverpool Eye and Ear Infirmary, and also Honorary Assistant Surgeon to the Eye, Ear and Throat Department of the Wigan Royal Infirmary.

Dr. Helen MacMurchy, of Toronto, whose work in connection with infant mortality, the care of the feeble-minded, and other public health questions is well known, has been appointed Assistant Inspector of Hospitals and Public Charities in Ontario, with special supervision over the feeble-minded.

FRENCH CLINICAL LECTURE

ON

OSTEOMYELITIS IN INFANTS. (a)

By PROF. E. KERMISSON, M.D.,

Professor at the Faculty of Medicine of Paris.

[Specially Reported for this Journal.]

Gentlemen,—We will devote our attention to-day to two little patients who have been admitted to our wards suffering from osteomyelitis.

Before doing so I should like to warn you against the old term, "osteomyelitis of adolescence," because it would be a grave mistake to suppose that osteitis is necessarily limited to adolescence. It is a disease which is met with in infants, in childhood, and even exceptionally in adults. Speaking generally, it may be met with at any period of osseous development, that is to say, until the age of twenty-five.

I present to you to-day these two cases to illustrate the occurrence of osteomyelitis in infancy. The first, a female infant, eighteen months of age, had previously been in excellent health. She was brought up at the breast, but she did not walk until late, and still presents traces of rickets. A fortnight since she had some stomach trouble and twelve days ago the mischief commenced in the left forearm. On January 10th the parents noticed what looked like a simple swelling in the left wrist, not accompanied by any reddening of the skin, but which steadily increased, spreading to the back of the hand and then to the forearm, thereupon assuming a frankly inflammatory appearance. Then, too, there was fever, the temperature oscillating round about 103-104° F.

On admission we found a red swelling, with obvious fluctuation, of the wrist and the back of the lower third of the forearm, especially on the radial side. The back of the hand was œdematous, but the movements of the joint were free. On examining the joint, I felt a sort of soft fremitus which made me entertain the possibility of detachment of the lower radial epiphysis, but this is of no moment, the point of interest being in reality the integrity of the joint since this disposed of the hypothesis of arthritis of the wrist. There was nothing to suggest lymphangitis or phlegmon, and I therefore concluded in favour of an osseous lesion, and as it was principally situated on the radial border, I diagnosed osteitis of the lower end of the radius.

This diagnosis was confirmed at the operation on the following morning. I made a vertical incision along the back of the forearm, and, having cut through the soft parts, I came upon a large abscess containing thick, homogeneous pus, some of which was set aside for bacteriological examination. With the grooved director I came down upon bare bone, and, pushing the director in farther, I made a counter opening on the skin on the opposite side of the limb. The fever at once subsided and the little patient seems to be improving rapidly.

Let us discuss this case for a moment, because it affords evidence of the fact that there is no such thing as chance in pathology.

Why should the osteomyelitis have fixed on the radius? Simply because it of itself is the column of support of the forearm. It is through the radius and not through the ulna that the weight is transmitted when we lean on the palm of the hand, and functional strain, as you know, attracts infection. But why should the infection choose the lower end of the radius? You know that of the intra-articular cartilages some are more active, more fertile, as Ollier used to say. Now, in the upper limb it is at the upper end of the humerus and the lower end of the radius and ulna that these "fertile" cartilages are found, and these cartilages are not only the points of election for osteomyelitis, but also of all bony lesions, exostoses, osteosarcoma, etc. It is not surprising, therefore, that the osteomyelitis should attack the lower end of the radius. I do not assert that it is never met with at the upper end, for I recently operated on such a case. I may mention incidentally that the latter is a very delicate operation, because, in order to get at the head of the radius, we have to cut through the supinator brevis, and there is great risk of damage to the deep branch of the radial nerve.

Osteomyelitis of the radius, indeed, is, however, a rather rare lesion, especially in infants. The few cases in my wards have always been in older children. In June and December, 1905, as it happens, I had occasion to lecture on two patients with osteomyelitis of the lower end of the radius, and in 1906 I advised my pupil, Mr. Delfosse, to select this as the subject of his thesis. In this thesis you will see that in the immense majority of cases this variety of osteitis runs its course without setting up arthritis of the wrist. This fact is explained by the anatomical relations of the parts. The epiphysial cartilage of the radius is not intra-articular. Only two of all the cases related by Mr. Delfosse in children, one two years and the other ten months of age, developed suppurative arthritis, but these were cases of primary invasion of the epiphysis, and, as you know, it is especially in young children that we get osteomyelitis of the epiphysis.

There is nothing particular to remark about the course of osteomyelitis. It may be complicated either by spontaneous fracture or detachment of the lower epiphysis of the radius. I may add that it is sometimes primary, sometimes secondary. Its importance from the orthopædic point of view lies in its ultimate consequences. The radius, for instance, may thereby have its development arrested while the ulna continues to grow, leading to the hand being thrown outwards on the forearm in a singularly disabling position.

The second case is that of a female infant, only six weeks of age, with osteomyelitis of the upper end of the right femur. She is the only child of healthy parents. At first brought up at the breast, she was subsequently handed over to a wet-nurse, who made up a deficiency of milk on her part by giving goat's milk. Everything went well for a fortnight after birth, but three weeks ago the way the infant began to scream when moved pointed to pain in the right hip, which was swollen.

On examination it was seen that the lower right limb was maintained in an attitude of repose, flexed, abducted and rotated outwards. The root of the limb was notably enlarged, red and infiltrated. On palpation internally we could make out a big, hard, œdematous mass, and at the back of the great trochanter we detected fluctuation, denoting a big collection of pus. For that matter the child presented other evidence of extensive suppuration: a bad general state, a high temperature, a yellow, waxen complexion, and a cachectic aspect, like that of old cancerous patients at the Salpêtrière. I should add that, on moving the joint, I found much latitude of movement, pointing to actual dislocation. I inferred from this that the abscess communicated with the interior of the joint *via* a hole in the synovial membrane.

(a) Clinical lecture delivered at the Hôpital des Enfants Malades, Paris, 1913.

On the morrow I plunged a trocar into the fluctuating area, giving exit to an ounce or so of greenish, thick, homogeneous, rather stringy pus, no doubt mixed with synovial fluid. The next day I was informed that the orifice of the puncture had become fistulous, so I decided to make a free incision; but on January 23rd, when about to do so, I found that all fluctuation had disappeared and there was only a trifling discharge of serum and grumous matter, so I held my hand.

At the present time the fever has fallen, the general health has improved, and the child is improving in appearance. Whether this intervention will suffice I cannot say, but it will always be time enough to make an incision when clearly indicated.

I mentioned just now that osteomyelitis of the radius was comparatively rare, but can we say as much of the second localisation? Assuredly not, for osteomyelitis in suckling infants always affects the big joints. That is the first point to be borne in mind. Then there is another. I spoke to you earlier of the integrity in most instances of the radio-carpal articulation in osteomyelitis of the lower end of the radius. Well, it is exactly the opposite in respect of this lesion, and here, again, the anatomical relations explain the reason. The neck of the femur does not form part, as you might be tempted to believe, of the epiphysis; it is the continuation of the upper end of the diaphysis and the epiphysis is only the globular head of the femur. The upper end of the femur therefore is intra-articular as well as its articular cartilage, and osteitis of this intra-articular extremity is necessarily accompanied by suppurative arthritis. It is of the greatest importance to bear this fact in mind, because it explains the highly improbable tales of so-called hyperacute coxalgia with grave constitutional symptoms and rapid death, which, in reality, are cases of osteomyelitis of the upper end of the femur with concomitant arthritis.

Familiarise yourself with the idea that osteomyelitis of the lower end of the radius is but rarely accompanied by suppurative arthritis and, on the contrary, that in osteomyelitis of the upper end of the femur suppurative arthritis is the rule. The reasons for this difference are anatomical, as I explained a few minutes since.

Klemm has published some recent statistics on osteomyelitis under conditions similar to our own—that is to say, in hospitals where children are admitted up to the age of fifteen. In ten years, out of 269 cases of osteomyelitis, there were 56 epiphysial cases, 43 being of the hip. In regard to age, 12 were infants under twelve months, 7 at one year, and 14 between three and six—*i.e.*, 33 cases under six years of age. As you see, osteomyelitis appears to be more frequent in early childhood, since, of 56 cases, 33 were before six.

As for osteomyelitis of the hip, the results are most striking. Of 31 acute cases, 19 were during the first three years of life, and of these 10 were during the first year. This confirms most strikingly what I said to you about osteomyelitis of the upper end of the femur being an affection of early childhood—of the suckling period indeed.

It is highly important for you to get to know osteomyelitis of the hip on account of its disastrous consequences if overlooked or mistaken. To begin with, on account of the softening of the bone tissue of the neck of the femur we may get coxa vara, though this is not what interests us most. The wearing away of the bone and the more or less complete destruction of the head may conduce to dislocation. Now, suppose we are dealing with an infant six weeks of age. His osteomyelitis has been treated by puncture or incision, the suppuration has ceased in a few weeks, and everybody has forgotten about what is taken to be a simple abscess. The infant, however, does not walk until very late—say, not until about eighteen months—then, too, he walks badly and wobbles most markedly. He is taken to a doctor, who, after listening to the history of the case, opines in favour of congenital dislocation, and, as a matter of fact, examination confirms that view, since there really is a dislocation.

But when you come to examine the hip very carefully you notice a tiny scar—say, in the neighbourhood of the trochanter. What is it? The friends then tell you that the child had a big abscess when six weeks of age, and thereupon you will understand the nature and cause of the dislocation. Moreover, you have only to radiograph the part. If it were a congenital dislocation you would find a perfectly constituted femur; whereas, if it be a case of past osteomyelitis, the head will, as a general rule, be totally destroyed.

You see how important it is to familiarise yourselves with these points from an orthopædic point of view, for it is obvious that, if no femoral head remains, it is idle to attempt reduction or to promise. Then, too, the prognosis in this variety of osteomyelitis is very grave. Such a lesion situated at the bottom of a deep, angular, joint cavity predisposes to stagnation of the pus, drainage is imperfect, and death occurs as the result of septicæmia.

As for treatment, Klemm advises resection of the head in every instance. I am of his opinion only so far as concerns older children and adults. I do not think this intervention necessary in young infants and sucklings. Though benign, so far as the result of the operation is concerned, it is potentially grave from an orthopædic point of view.

Bacteriologically the staphylococcus seems to be the most frequent agent of osteomyelitis, though the nature of the micro-organism does not, as Lannelongue suggested, furnish trustworthy prognostic data. Staphylococcus and streptococcus are alternatively virulent and benign. The only conclusion which we are justified in drawing is that osteomyelitis with the pneumococcus is usually benign.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by J. Hugh Thursfield, M.D. Oxon., F.R.C.P.Lond., Physician to the Metropolitan Hospital, Assistant Physician to the Hospital for Sick Children, Great Ormond Street, London, &c. Subject: "Enlargement of the Spleen in Children."*

A tablet was unveiled at Lancaster last week recording the place of birth of Sir William Turner, K.C.B., Principal and Vice-Chancellor of Edinburgh University, ex-President of the General Medical Council, and ex-President of the British Association. His fellow-townsmen, Professor Whewell and Professor Owen, are similarly commemorated.

ORIGINAL PAPERS.

APEX-TREATMENT
FOR
PULMONARY CONSUMPTION.

By WILLIAM EWART, M.D.Cantab., F.R.C.P.,

Consulting Physician to St. George's Hospital and to the Belgrave Hospital for Children; formerly Assistant Physician and Pathologist to the Hospital for Consumption, Brompton.

(Continued from p. 146.)

IV.

THE DATA FOR THE MECHANICAL METHODS OF PREVENTION.

Apex "inflation" and "deflation" are seen to be not merely a side aspect, but actively concerned in the entire local circulatory, no less than in the aerial function in disease as well as in health. Nevertheless, in our treatment they are still unsettled theoretical quantities, *à priori* reversible, and, in fact, abruptly reversed at its different stages as any contradictories might be which were of no account; and yet they are thought worth while, and even essential to reverse. This is an attempt to submit that question to the experimental decision of clinical observation.

For Prophylaxis apex-inflation is unanimously approved, on the basis of demonstration. The earliest observations are linked with the latest in the name of the "Freund-Hart theory." Though Prof. B. Stiller, of Budapest, looks upon the phthinoid chest itself as a post-natal development grafted by infantile tuberculosis upon some of the members of the larger group of "congenital asthenics,"—the congenitally "asthenic thorax" being identified by its *costa decima fluctuans* (Stiller), in addition to a short first cartilage (Freund)—he does not question the practical efficacy of early hygiene and apex-expansion as a protection against the apical affection. Hygiene deals with the tuberculosis, and apex-expansion with its localisation.

Granted that Römer may be right in regarding all phthisis as a severe re-infection of a subject previously marasmised, but only temporarily immunised, by a specially severe infantile infection, this does not detract from the clinical proof of the local mechanical immunising power of apex-expansion. This influence has been counter-tested by Bacmeister, who produces, in growing rabbits, by means of an apex-constricting wire, a *contra naturam* "apex" localisation of the artificial infection. The clinical data in support are not so precise, but of much wider range; and they cannot be disregarded as they converge to the conclusion that in the erect human species, whilst the lung is specially immune the apex is specially liable, and that its structural immunisation may require to be assured by specially local and mechanical means. In addition to the favourable results already achieved in juvenile prevention by gymnastic training, some of the evidence in question is derivable from a study of the physiological apex-immunities and of the pathological apex-immunities, which we shall proceed to mention.

The Relative Physiological Apex-Immunity, that of the robust, lies in the fortunate combination of a first-rate thorax and powerful heart with the benefits of an all-round hygiene. Among its factors, the mechanical one is represented by the apex features of good shape, good bulk, and good range of activity; and these we may provisionally accept as a standard of comparison for other immunities generally attributed to a pathological origin.

The Relative Pathological Apex-Immunities, which we notice on the strength of their traditional rather than of any ascertained statistical standing, are the familiar ones of surgical tuberculosis or scrofula, of mitral disease, of rachitis or kyphosis, all of which are juvenile, and of emphysema. They are all susceptible of a mechanical explanation, although emphysema alone has been so explained. *In Scrofula*, the general immunising effect of auto-inoculation does not of itself account for the fact pointed out by Sir F. Treves that whilst scrofulous manifestations may recur from a recurrence of depressing conditions, eventual pulmonary disease is much less common. We may still suspect that the wearing of long splints and bandages or of plaster round the chest may relatively favour apical expansion; whilst recurrent pyrexias may sufficiently exercise the heart and the apex to prove most often an efficient insurance against future apex risks.

In Mitral Disease, and particularly stenosis, Rokitansky attributed the relative protection to a blood overcharge. Bier, the clinician, founded upon that "anatomical" explanation the *rationale* of his entire mechanical method; and Kuhn, that of his own application of it to the lung. All three have overlooked a plausible "physiological" explanation. "Panting" stenosis *has to breathe* with the congested apex, when refused adequate service by the much worse congested base.

In the mysterious immunity alleged to belong to *Rickets*, and to kyphosis of rickety derivation, nothing could be more obvious than the mechanical factor. In its pigeon-breasted softening the rickety thorax becomes the obstacle instead of the help to respiration; and the same is true of the passive elevation of the diaphragm, so long as it remains uncorrected. The apex, least exposed to these influences, suffers least hindrance, and is called upon by the disease to assume temporarily a leading office in the respiratory function. At that plastic stage a few weeks will suffice to fashion the upper ribs and their attachments to an attitude and to a shape which in later life it takes years of emphysema to develop. Some of this change is permanent, and has to be taken into account at least as a part, if not as the essence, of any lasting apex-immunity.

V.

APEX-INFLATION OR APEX DEFLATION FOR TREATMENT?

The Argument from "Risk."—Imperfect apical inflation being a recognised characteristic of the "predisposed," and admitted by common consent and practice to be the chief mechanical ætiological objective for preventive correction, it is apparent that rest pure and simple has, in terms of the apex, the value of deflation. "Apical rest" means *relative "apical deflation"*; but when, as heretofore, it has to be obtained through the general rest cure, it means much else. The mechanical apex-rest is a vanishing quantity, as compared with the total body rest. How shall we assess to the one and to the other their respective share in any apex result, whether good or bad? We must remain in the dark on this practical point of treatment so long as the two agencies are not systematically studied each for itself; our conclusions remain merely inferential, on indirect evidence. The theoretical *onus probandi* is heavy for those who believe that the measure which is successful for prevention is bad for treatment. Still greater the uncertainty in timing that radical change, where no guiding landmark yet emerges between the "prepulmonary" tuberculosis and its pulmonary stage. Hitherto the proposition that the preventive help of apex-inflation turns to harm for treatment has no other support than the helpless *argument from the risk* of auto-inoculation and of strain. This might as well have stopped the whole history of our bacillo-therapy after the disasters of 1890; or might to-day be forbidding us to cure our late phthisis by pneumothorax. And yet at that early stage what does the risk amount to? At the apex the thoracic excursion is feeble at the best; how feeble must be the alveolar excursion. The stricken alveoli are plugged and immobile, surrounded by tissue which is not yet rotten and fragile; are they likely to give way and " open up " the lesion whilst the healthy alveoli bring to them all round the support of their inflation? That peripheral inflation and support is the acknowledged mechanism of the partial repair after pulmonary excavation; how much more efficient might it not be where there are no big gaps to fill? If, unknown to our examination, cavernules should have already formed, still served by a comparatively healthy bronchial outlet, shall we withhold from them at that time of election the helpful lateral pressure for evacuation and compression which is analogous to a " pneumothorax cure "? The risk of massive auto-inoculation is taken by Forlanini; here it could neither be massive or abrupt, and each successive inflation would likewise tend to reduce it. But the old prudential argument was not based upon auto-inoculation and was not very conclusive. This is its authoritative statement in Nothnagel's system (*a*): " For years I have absolutely banished forcible inspirations in the form in which they are generally prescribed, regarding them as nothing less than dangerous and harmful. I prefer to advise the patients to breathe in *slowly* and not too deeply, and then to breathe the air out again without effort, in order to further the removal of the products of expectoration. I, myself, and what is of no less importance, my patients are perfectly satisfied with the results. Brehmer, Volland and Liebermeister long ago gave warning against the dangers of pulmonary gymnastics."

The Arguments from Collateral Facts.—Largest in bulk is the testimony from the early and latent spontaneous cures, more numerous we are led to believe than the progressive cases of declared phthisis. These cases get well not through apical rest but through increased apical work, inasmuch as under the slight relative dyspnœa the usual avocations cost more respiratory effort; but chiefly perhaps owing to the usual prevalence of cough as a direct agent of apex-inflation. But the best argument is the demonstration afforded by artificial pneumothorax. The evidence is absolute, for there is only one lung, and that lung is inflated not partially or intermittently but steadily and to the utmost. The apex itself is the section least hampered in its expansion whether by the direct gaseous pressure or by the heart and mediastina which it displaces. In the successful cases its early lesions, so often present, and often even " open " lesions, get well under that extreme treatment; showing what " *unilateral breathing* " can do for the early stage. More advanced cases generally succumb; what else could we expect after depriving them of one third of their total breathing surface? The wonder is that they last so long; and this seems to be due to the help of inflation for a badly-damaged apex. They prove at the least the harmlessness of apex-inflation, even in the advanced stage. The others clearly prove its healing power in the earlier stages.

Lastly the experimental argument is now available. " Graduated labour " is a conclusive proof that apex-inflation does no harm; neither at the closed stage, nor at the healing stage of the late lesions. Then why further delay that simple and safe clinical experiment for the initial stage? Let us cautiously study whether we may not have been wrong, at least in a majority of cases, in systematically deflating the apex by rest, instead of giving it its cure by an initial " graduated system of *apex-activity*."

CHRONIC MEDIASTINITIS: ITS CAUSES, FORMS, SYMPTOMS AND TREATMENT.

By PROFESSOR C. LIAN, M.D.,

Director of Clinical Medicine at the Faculty of Medicine of Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

(Concluded from our last issue.)

TUBERCULOUS MEDIASTINITIS.

As a rule chronic tuberculous inflammation of the superior mediastinal tissue is discreet. It is accompanied by peritracheo-bronchial adenopathy and runs a very slow course. It very rarely gives rise to as striking a symptomatology as the variety due to syphilis, and in any event it is always very difficult to distinguish the troubles due to the glandular enlargement from those caused by the mediastinitis.

The inferior variety—chronic inferior tuberculous mediastinitis—which is particularly frequent in children, occurs in three principal clinical forms.

(1) *Mediastino-Pericarditis.*—This is the well-known clinical picture of tuberculous cardiac symphysis accompanied by asystole bearing mainly on the liver. We need only mention *en passant* the physical signs of cardiac symphysis—*viz.*, undulation of the chest wall, pluricostal systolic retraction in the precordial region and fixity of the apex.

(2) *Mediastino-Pleuritis without pericardiac symphysis but with hepatic asystole.*—In this form patients present the syndrome of hepatic asystole, but the asystole is provoked purely by the mediastinitis independently of any cardiac symphysis and is due to pressure on the inferior vena cava by bands of mediastinal fibrous tissue. The prognosis is said to be less gloomy than in the cases with symphysis. As these lesions often complicate tuberculous pleurisy they are usually associated with extensive pleural symphysis.

(3) *Mediastino-Pleuritis with Dextrocardia.* — Here right pleural symphysis associated with retraction of the thoracic wall and an atelectasic or sclerosed lung is accompanied by fibrous mediastinitis. Under the influence of these various processes the heart has been more or less markedly deviated to the right and fixed in this new position.

DIAGNOSIS.

The diagnosis of mediastinitis may be envisaged under three conditions:—

(1) In well-marked superior mediastinitis the syndrome is easily recognised. The only difficulty that presents itself is to determine the mediastinal affection which is causing the symptoms.

(2) In inferior mediastinitis in presence of hepatic asystole in which it is necessary to establish its mediastinitic origin.

(3) Lastly, in the abortive cases the diagnosis is particularly delicate when called upon to establish the fact that the pathological disturbances are of mediastinal origin and are due to mediastinitis.

(*a*) " Tuberculosis," by Prof. G. Cornet, 1899, English edition 1904, p. 540.

Superior Mediastinitis.

In presence of signs of obstruction of the superior vena cava or of one of its branches we are justified in suspecting mediastinitis. The respiratory signs are not as easy to interpret, and are apt in the first instance to direct attention to the throat, larynx or lungs. Examination of these organs and the, as a rule, dramatic intensity of the symptoms, generally enable us to steer clear of error. The only difficulty is to establish the cause of the mediastinitis.

In children we should, of course, at once suspect tracheo-bronchial adenopathy because superior mediastinitis, if present, usually accompanies the latter and may be masked thereby.

In an elderly subject our thoughts naturally turn to malignant tumours of the mediastinum, either primary or secondary. Associated cachexia would tend to confirm that suspicion.

Lastly, in the adult, in whom superior mediastinitis is most frequent, the diagnosis presents two aspects :—

(*a*) If the syndrome has come on rather rapidly we may suspect pericarditis with much effusion, and examination of the heart will show whether such is the case; a mediastinal pleurisy—fever, a latero-vertebral dull band (posterior effusion) or an increasing dull area over the heart would be in favour of pleurisy. But these physical signs are inconstant and difficult to make out, moreover, mediastinitis may itself be accompanied by a rise of temperature.

(*b*) In presence of a chronic process we have to eliminate three mediastinal affections—*viz.* :—

Tracheo-bronchial adenopathy, rarely marked enough to determine *per se* mediastinal troubles unless it happens to be associated with a malignant tumour in the neighbourhood. As for lymphadenia this could only be diagnosed clinically when the peripheral glands are similarly affected or the leucocytic formula is found to be modified.

A malignant growth in the mediastinum. In this case our diagnosis will be based especially on the state of the general health aided possibly by radiography.

Also, and especially, aneurysm of the aorta. When dilatation is associated with a syndrome of venous compression the former will in all probability have antedated the latter and is discovered on examination so that absence of the signs of aortic aneurysm in presence of venous compression is suggestive of mediastinitis. Much more difficult is the diagnosis of deep ectasia with compression of bronchi or nerves—in fact, it may be clinically impossible, in which case we must have recourse to radiography as the only means of making the distinction.

(2) In inferior mediastinitis our attention is awakened by a more or less pronounced syndrome of hepatic asystole. We must then examine the circulation and the lung for the cause of this asystole. We must bear in mind the possibility of mediastino-pericarditis, especially if there be undulation in the precordial region, fixity of the apex and systolic retraction of the thoracic wall. Absence of fixity of the apex would point in favour of inferior mediastinitis with or without external pericarditis.

(*c*) Lastly, in the abortive forms every conceivable error is possible, and in most instances the functional disturbance will be attributed to any other cause than mediastinitis. Consequently we must bear this possibility in mind in all cases of dyspnœa, pain, etc., for which no adequate cause can be discovered. In case of doubt or uncertainty have recourse to the X-rays, especially from the front and in the anterior-oblique position.

The appearances with the X-rays are as follows :—

(1) We may see round the large vessels in the superior mediastinum, or more frequently at the upper part of the clear median space, a mass varying in size from a pigeon's egg to that of a tangerine orange, unequally opaque, with ill-defined borders.

(2) Or we may make out fibrous bands crossing the mediastinum in various directions.

(3) Lastly, in inferior mediastinitis, we get a cardiac shadow bounded on both sides by a dark band of varying width. If there be symphysis we shall note the fixity of the apex. There is also the important sign discovered by Broadbent—*viz.*, if we examine a healthy subject in the sagittal position when he takes a deep inspiration the apex of the heart is seen to separate from the shadow of the wall; it seems to be beating in space. In presence of adhesions between the pericardium and the sterno-costal wall the apex does not separate therefrom but remains fixed even on deep inspiration.

The fact remains that the interpretation of radiographic appearances is a matter of great delicacy, and we have in particular to differentiate mediastinitis from other affections visible with the rays.

(*a*) Mediastinal tumours give on the screen an irregular mass pretty uniformly opaque, with sharp, irregular edges, the mass, on the whole, being bigger than that of mediastinitis.

(*b*) Tracheo-bronchial adenopathy is seen as little dark patches, the size of filberts, especially in the hilum of the lung and more on the right than the left. The diagnosis is difficult in superior tuberculous mediastinitis which is always associated with adenopathy. We shall suspect the existence of mediastinitis when the rest of the mediastinum presents a diffuse unequal greyish tint.

(*c*) Lastly, aneurysm of the aorta presents itself in two forms :—

If the aneurysm is not surrounded by mediastinitic thickening we get a rounded, well-defined uniformly opaque tumour, in the site of one or other segment of the aorta which can be seen to pulsate.

If there be concomitant mediastinitis, which is often the case, we see an opaque, rounded mass, with less well-defined margins which only pulsates in parts.

We may, as Sergent has pointed out, watch the transformation of a non-pulsating tumour into a pulsating one consequent upon a course of anti-syphilitic treatment, which has for effect to free the dilated vessel from its mediastinitis. Radiology, of course, does not always give as precise information as that just described, and the interpretation of the appearances on the screen is often a rather difficult matter. Nevertheless the X-rays afford the best available means of arriving at the diagnosis of an affection which, on account of its situation, escapes recognition by ordinary methods of exploration.

Ætiological Diagnosis.

It is important to try and discover the cause of the mediastinitis, especially in view of the possibility of a syphilitic origin. Speaking generally, in the child we get mediastino-pericarditis with hepatic asystole, mostly of tuberculous origin, though it may be mixed syphilis and tuberculosis, while in some instances it is rheumatic. Pure syphilitic mediastinitis is quite rare, but when present it is almost always the superior form.

In the adult, mediastino-pericarditis is less frequently met with and if present is probably tuberculous or rheumatic. Superior mediastinitis is almost always syphilitic. In any case we must make close inquiry for a history of syphilis, not omitting the Wassermann reaction. Even if the latter prove negative antisyphilitic treatment should be instituted if there remain the slightest uncertainty as to this.

Treatment.

There are two conditions in which we are called upon to institute energetic treatment of mediastinitis.

(1) In presence of syphilitic mediastinitis intensive treatment is called for, either with soluble mercurial salts, especially the cyanide of mercury, by the intravenous method, or with insoluble salts (especially calomel) or the arsenicals: hectine or salvarsan, in prudent doses.

The influence of the treatment is remarkable at the period of gummatous infiltration and that of invasion of the mediastinum; it is less efficacious when the mediastinitis is fully constituted.

(2) In mediastino-pericarditis freeing the heart by Brauer's method has yielded good results in some instances. It is indicated in cases of mediastinitis with pluricostal systolic retraction at the apex if the myocardium is not exhausted.

In tuberculous mediastinitis we have recourse to general antituberculous measures, but in most cases we shall only be able to employ palliative means and first and foremost patient must be placed at rest under hygienic conditions of life, because this alone often has an excellent influence.

PRESIDENTIAL ADDRESS (*a*)

By SIR THOMAS BARLOW, BART., K.C.V.O., M.D., F.R.S.,

Physician Extraordinary to His Majesty the King, President of the Royal College of Physicians, London.

Your Royal Highness, My Lords, Ladies and Gentlemen,—My first duty is to express our gratitude to His Majesty the King for graciously consenting to be the patron of the Seventeenth International Medical Congress. My second duty is to thank His Royal Highness Prince Arthur of Connaught for representing His Majesty on this occasion in the inauguration of the Congress and for the important address which he has given to us. My third duty is to acknowledge the kindness and the consideration of Sir Edward Grey, the Minister of Foreign Affairs of this country, for the official and hearty welcome which he has given to our foreign members.

In Praise of Famous Men.

A whole generation has passed away since the International Medical Congress last met in London. What a magnificent galaxy of talent in medicine, surgery, and pathology was gathered round the Prince of Wales, who was our Royal Patron at that time! It is fitting that we should follow the admonition of Ecclesiasticus and praise famous men and the fathers that begat us.

Our President, Sir James Paget, was a great clinical pathologist. His mind was stored with all that was then known of the morbid anatomy of surgical disease and injury, and of the family relationship of the different diatheses. He was a splendid teacher and possessed a lucid eloquence and a moral fervour not excelled by any of his contemporaries.

Jenner and Gull, Wilks and Gairdner, were our great teachers of clinical medicine. Each of them based his knowledge on the sure foundation of the *post-mortem* room and the hospital wards. We shall not see their like again, for their careers began before the days of specialisation, and they were amongst the last of the great general physicians of our time.

Hughlings Jackson was the philosophical exponent of the new neurology. Many of his forecasts were verified by the experiments of David Ferrier, of which I may say there was a remarkable demonstration at the 1881 Congress.

Jonathan Hutchinson was the patient, accurate recorder of the natural history of disease in multitudinous departments, and, characteristically enough, he was the organiser of our Congress clinical and pathological museum.

The pioneers of abdominal surgery—Spencer Wells, Thomas Keith, and Lawson Tait—were with us. Huxley, the most brilliant expositor of natural science of his time, discoursed to us on the relations of medicine and biology.

William Bowman, whose work on the minute anatomy of the eye was the foundation of modern English ophthalmology, was one of our most useful members.

Last of all the Englishmen whom I will mention was our great Lister, then in the zenith of his grand career. He has but lately been taken to rest in the fulness of years, and we commemorate him to-day in the medal of our Congress.

Our foreign brethren were not less illustrious in the bede roll of medical and surgical achievement.

Virchow, the Nestor of morbid anatomy, honoured and beloved by us as by his own countrymen, delivered a fine historical discourse on the value of pathological experiments. Volkmann gave a critical survey of the recent advances of surgery.

Robert Koch gave what may truly be called a path-breaking demonstration of the microbial findings in several morbid conditions, and he illustrated their characteristic growth on different organic media.

Von Langenbeck and Esmarch spoke for military surgery. Donders and Snellen for ophthalmology. Baccelli, Murri, and Pantaleoni represented Italian medicine. From the United States came Austin Flint, the accomplished physician and master of physical examination; Billings, prince of medical bibliographers; and Bigelow, the famous surgeon.

The great French school was represented by Brown-Séquard and Charcot, Lancereaux and Bouchard and Verneuil and a host of others; but there was one great Frenchman with us who towered aloft amongst all his contemporaries and who, though not a medical man, exercised by his discoveries a profound influence on the medicine of the world, and that was Louis Pasteur. In his address on vaccination in relation to chicken cholera and splenic fever he gracefully linked his most recent researches with the time-honoured labours of Edward Jenner on cowpox.

Time fails me to speak of other great and honoured names, but surely we may say there were giants in those days.

The Parting of the Ways.

Now let us realise to ourselves that the Congress of 1881 marked not the parting of the ways but emphasised the notable fact that the parting of the ways had already been passed. The times of superstition, of empiricism, and of transcendental speculation had vanished. But what of the period of accurate and detailed observation? That was neither superseded nor completed, but it was already supplemented and redirected into more fruitful channels by the new development of *experimental methods*.

If it had not been for the work of Pasteur, Lister, and Koch, which was expounded to us 30 years ago, how poverty-stricken would have been the output of medicine and surgery in this our Congress of 1913.

The great men—both observers and experimenters—of whom I have spoken were like mountain peaks towering above the plain of ordinary medical humanity, and we sometimes sadly ask where are the mountain peaks now? That is a shallow and unenlightened question. For indeed, thanks to the unremitting labours of workers in multitudinous paths, we have attained a glorious heritage, not of high mountain peaks and deep valleys, but a lofty and magnificent tableland of well-ordered and correlated knowledge.

Consider the bare fact that the 15 sections of the 1881 Congress have, by the inevitable specialisation and concentration of work, become 23 sections and three subsections in 1913; but so imperative is the demand for mutual conference that we have no less than 14 meetings arranged in which sections have found it desirable to discuss various problems in joint session.

(*a*) Delivered before the Seventeenth International Congress of Medicine on August 6th, 1913.

In what ways have we pursued and expanded the work of our fathers?

The Developments in Microbiology and Parasitology.

First, unquestionably in the development and application of bacteriology. Koch's great discovery of the life history of the tubercle bacillus was published in the year after the London Congress, and what an enormous body of knowledge has grown out of that discovery! We are learning to discriminate between the essential and causal factors of disease and the concomitants, such as combined and terminal infections. The by-products and the antibodies developed to neutralise bacterial life, of which we see the beneficent *rôle* in Nature's own cure of an acute specific disease, have been made to yield their share in two important methods of treatment—viz., serotherapy and vaccinotherapy. We have also faced the problem of strengthening the phagocytosis of the patient.

I need not dwell on the history of the Klebs-Loeffler bacillus and the causation of diphtheria, nor on the indubitable efficacy of the most important of all the antitoxins, nor on the singular parallelism between the bacteriological findings in a typical throat exudation with the ambiguous symptomatology which clinical observation reveals. Nor need I dwell on the extension of bacteriological investigation of typhoid which has been fruitful in new measures of prophylaxis and defence of the community.

We have learned something about the natural history of the ultra-minute organisms which as "filter passers" elude our microscopic investigation.

There are still great gaps in our knowledge of the infective organisms of the specific diseases, but it is a gain to have learnt from the study of recent epidemics that infantile paralysis must be grouped with the infective diseases, and, thanks to Flexner, we know many of the reactions of its elusive organism.

Great advances have been made in protozoology, in helminthology, and indeed in the whole subject of the relation of the parasites to the diseases of man and animals.

In tropical diseases these studies as well as bacteriology have brought about a rich harvest.

Mediterranean fever, plague, malaria, sleeping sickness, have all yielded more or less of their secrets. Sometimes the whole cycle of the disease has been discovered, rationalised in every respect, and its successful treatment has been evolved. In other cases, as in malaria, sleeping sickness, and yellow fever, where only parts of the natural history of the disease have been elucidated, nevertheless enough real knowledge has been acquired to enable important though sometimes costly hygienic measures to be successfully employed. Here it is fitting that we should offer our homage to our American brethren for their splendid hygienic work in Cuba, in Panama, in the Philippines, and in Costa Rica, and for the efforts which they are organising for a world-wide crusade against ankylostoma disease.

An Outline of Progress in Many Directions.

Chemical pathology has widened our knowledge and our resources, and the mystery of immunity has been to some extent illuminated.

The detailed examination of the morphological elements and the chemical characters of the blood and other body fluids has eventuated in the rewriting of some of our physiology, and the pathological extension of the knowledge thus gained has improved the diagnosis and the treatment of several diseases.

Thirty years ago Ord demonstrated to the Congress of that time examples of the disease which he had defined as myxœdema, but which, with surer instinct, Gull had described as a cretinoid state in adults. The gradual evolution of the doctrine of thyroid insufficiency and of its therapeutics is a model of induction. And this important discovery has given a great impetus to the whole study of internal secretions as well as to the employment of organic extracts, of which the last and most interesting is that of the pituitary body.

The empirical and then the experimental study of small variations in the ordinary diets of adults and children and infants in different social strata and in different countries has been fruitful in many unexpected ways. The great milk problem is still with us, but we have learnt the blunders of our early generalisations. Cleanliness in the milk-supply from start to finish has a far more exhaustive meaning than in days gone by.

The curious disease beri-beri, which some of us have long thought had parallelisms with scurvy, has been shown, at all events among rice-eating people, to depend on the loss of the nutritive material just internal to the pericarp which the ordinary process of milling removes.

The patient study of chronic alcoholism has opened up a new chapter in nervous diseases. The routine traditional employment of alcohol in disease has happily been largely discredited. The open-air treatment of all forms of tubercular lesions has had a wide indirect influence not only on the treatment of other chronic ailments but on the daily life of the people.

The recognition and radical treatment of oral sepsis due to damage to the gums in consequence of various disorders of teeth has been followed by remarkable benefit. A strong case has been made out for intestinal stasis as a cause of various forms of malnutrition and for operative measures in dealing with slight mechanical obstructions, and on this subject we hope for further evidence.

The additions to diagnosis yielded by X-ray exploration are like the creation of a fifth sense, and its curative applications and those of radium are the opening of a new chapter of therapeutics.

I venture to hint that medicine had now and then led to the rewriting of some chapters of physiology, and I may add that recent researches on diseases of the heart have led to the re-editing of neglected knowledge of the minute structure of heart muscle and of orderly and disorderly mechanism of its movements.

The Triumph of Surgery.

Of the magnificent triumphs of the surgery of this generation it is beyond my power adequately to speak, but I can refer to the wide fields opened up through the beneficent protection of Listerism. We are staggered by the reasoned and calculated audacity of our brethren when sinuses of the skull are drained, cerebral abscesses evacuated, cerebral tumours removed, the pituitary body even being investigated, when pleuro-pericardial adhesions are freed to the great relief of the heart, when different parts of the alimentary canal are short-circuited, and when one or other damaged viscus is removed either entirely or in part. The active coöperation of surgeons and physicians has gained for us some knowledge of what Moynihan and others have happily described as "living pathology," and we gracefully acknowledge the invaluable information of correlated symptoms, signs, and morbid conditions, and the statistics of comparative frequency which surgical experience has brought to the common store.

The supreme gain, after all, is that many more useful lives are saved than in the last generation, that the realm of grave and hitherto incurable disease is invaded on every side, and that the danger of operation *quâ* operation is retreating to a vanishing point.

It is impossible even to enumerate the varied ways in which medicine has coöperated with economics, social legislation, and philanthropy, which we sum up briefly as public health. The school-house and the scholars, the home of the poor, the colliery and the factory, the dangerous occupations, the sunless life of the mentally deficient, have benefited, and will benefit still more by its friendly invasion. And I venture to foretell that not many years hence every department of life and work shall be strengthened and purified and brightened by its genial and penetrating influence.

Conclusion.

Surely I have said more than enough to justify my contention that we have come into a goodly heritage, and that that heritage is like a lofty and magnificent tableland of knowledge and efficiency.

The gaps are being filled; we are no longer isolated, but are working side by side on adjacent areas which are inseparably connected. Every day we gain fresh help from the auxiliary sciences, and we realise more and more the unity and the universality of medicine.

Brethren from foreign lands, we thank you for the treasures new and old of observation and experiment and of a ripe experience which you have brought to this Congress for the common weal. I venture to affirm that the output of work of the Congress week in its 23 goodly volumes will astonish civilised countries by the amount of its solid work. I welcome you to our dear country, this ancient home of freedom, and I speak not only for the medical men of the British Isles, but for our brethren of the overseas dominions of this great Empire, who join with us in our cordial greeting.

May this Congress add to the common store of fruitful and useful knowledge, may it increase our good fellowship, our mutual understanding and coöperation, and may it help to break down the barriers of race and country in the onward beneficent march of world medicine.

MEDICAL PROGNOSIS: ITS METHODS, ITS EVOLUTION, ITS LIMITATIONS. (a)

By A. CHAUFFARD, M.D.,
Professor of Clinical Medicine in the University of Paris; Member of the Academy of Medicine.

Medical Prognosis! Is it not for us the daily problem, the anxious question which is constantly being put to us and which we put to ourselves? Ever since there have been sick patients and men who endeavour to relieve them and to restore them to health the same query has come up in every case: Will a cure be effected and by what therapeutical means? Prognosis and treatment, such were from the very first the two instinctive needs, the two immediate demands of the sick man. It was only at a later period, at a more advanced stage of medical culture, that the previous need became felt of diagnosis, which is a notion of purely intellectual and logical order. But if diagnosis has been the latest of our acquisitions, it has now taken its proper rank—the first. What physician, failing an accurate diagnosis, could venture on a prognosis or prescribe a treatment? An entirely modern idea—but one which should imbue our minds nowadays—is that of defining in each particular case the mutual relationship between those three fundamental elements of medical judgment: to know, to foresee, to act. Instinctive in the remote ages and, later, hesitating and seeking its way for a long period of time, the art of the physician tends to become more and more rational and systematic. It is the passing from art to science which our epoch is striving hard to achieve, often with success. In this uninterrupted evolution medical prognosis has not remained at a standstill; almost before our own eyes, and by the mere progress of contemporary science, it has undergone a gradual change. Its methods are being modified, its limitations are being carried further back every day; it is in a state of perpetual transformation. The present time is perhaps a suitable one for a general survey of our present position and for an appraisement of our acquisitions and desiderata. Such is the task I intend to attempt this afternoon before you. In the history of medical prognosis a large place should be ascribed to the Hippocratic era, and it is impossible to peruse those venerable writings without a feeling of deep admiration. In those days the physician, having no technical means of investigation at his command, could naturally have but a purely objective vision of his patient, but how penetrating was this vision, how skilful in grasping, coördinating, and interpreting the most minute details! What a searching study, what a constant scrutiny of the prognostic signs derived from the general condition of the patient and revealed by his facies, his position in bed, the movements of his hands, his breathing, his sweating, the state of his hypochondria, his dropsical swellings, his sleep, his urine, his stools, his vomit, his sputum. The book on "Prognosis" is only concerned with acute febrile diseases, but from its descriptions there is nothing to be omitted. "The best physician appears to be the one who knows how to know before"; such is the opening sentence of those admirable pages, so replete with clinical observation and medical philosophy. The body should always be considered as a whole and "all things should be judged by the study of signs and the estimation of their relative value." Such are the earliest sources to which we must ever revert. Those primordial notions have lost none of their value, and if we have added much we have parted with nothing. To this day those objective data are amongst the things that no clinician has the right to neglect, and the general impression they suggest at the patient's bedside leads us to pretty much the same prognostic conclusions as of old. For more than twenty centuries medical observation went no further and was restricted to the same elementary information until the day when new methods were added to the ancient practices, rendering possible the analysis of morbid disturbances. Thenceforth it is by the analytical method, with the help of a more and more penetrating *technique*, that medical inquiries progress; at the same time, more direct paths are open to prognosis. The modern era begins with Auenbrugger and Corvisart, who introduced percussion; with Laennec, the immortal inventor of auscultation; with Richard Bright, the creator of renal pathology. By those memorable discoveries the whole of medicine was at once transformed. Direct exploration became possible and efforts were made, in Laennec's own words, "to place in regard to diagnosis internal organic lesions on the same line with surgical diseases." To detect morbid changes in the living subject, to ascertain their degree and evolution, amounted to creating modern diagnosis and to giving prognosis more certain bases. It amounted also to demonstrating all the importance of a new science, pathological anatomy, which by its precise descriptions was going to corroborate and check clinical investigation and to direct medicine for a time towards the exclusive quest for lesions and for organic changes. To detect the lesion in the living subject, to identify it in the cadaver, and to deduce therefrom diagnosis and prognosis, such became the system of what was to be, for more than half a century, Organicist Medicine—a noble system which contained a large share of truth, but a narrow doctrine which tended to confuse the lesion with the disease which caused it. Need I add that if we are mere organicists no longer, we have nevertheless cast aside or forgotten no part of our predecessors' labour? Their work rests on the ancient fabric like a new geological stratum: on this stratum we have erected our modern constructions, more extensive and solid because they rest on larger and deeper foundations.

Advance in Technique.

The succeeding stage is marked by the influence of Claude Bernard's memorable work. With him pathology became deviated physiology, and disease became a disturbance of normal functions. We can recognise a morbid state and alter its probable course and consequences only if we are acquainted with the functional disturbances it causes. Without this essential notion how could we scientifically conceive the prognosis of a lesion of the heart, or liver, or kidney, or of the digestive or respiratory systems? Modern effort tends each day to greater advances along the paths opened up by Claude Bernard. With our improved instruments and laboratory *technique*, through our researches on the blood and body-fluids and on cytological reactions, we aim at gauging accurately the functional value of the various structures, the organic reactions of defence, the substitutions and compensations as well as the morbid synergical actions that take place in the human system. We physicians now strive to reason and to act as physiologists or, better still, as biologists. Our system of analysis makes use at the same time of the methods, now closely associated, of clinical medicine and of experimental pathology. It attempts to dissociate the infinitely complex problems of pathogenesis and the relationship between causation and secondary reaction. Nor can we arrive at a prognosis unless we take all those factors into account. Thorough diagnosis is almost one with scientific prognosis—at least, they constitute two closely connected ways of considering the same facts. If we remember all that we owe to contemporary hæmatology, to biological chemistry, to electrology, to radiology, we see how inseparable are the notions of diagnosis and prognosis thus obtained. Of equal importance, both for diagnosis and prognosis, are the temperature charts, the curves of urine and weight, the cardio-vascular tracings such as we have learned to take and interpret them from Marey and from James Mackenzie, the research in the blood of bactericidal properties, of agglutinins, of opsonins, the analysis, both qualitative and quantitative, of the various constituents of the serum. We arrive at the same conclusion if we consider the history of the leucocytes of the blood, with their chemiotactic and phagocytic reactions. Thus prognosis takes its immediate share in all the advances of diagnostic *technique*. This unceasing progress might make us imagine that there are no limits to its possibilities. It certainly is far from having reached its future boundaries, although we feel hemmed in by its present-day ones. These we shall attempt to define later.

(a) Abstract of the Address in Medicine delivered at the Seventeenth International Congress of Medicine, London, 1913.

REMOTE PROGNOSIS.

Medical prognosis, then, is a very complex matter necessitating the consideration of multiple criteria. Yet, if thus strictly considered, it would still be very incomplete inasmuch as it would not be taking the future into sufficient account. Now the future, to us physicians, is a preoccupation inseparable from the actual disease we are treating. This is a recent notion, it is true; for it was formerly imagined that a disease cured had no morrow. How great was this error and how far we now are from such a fallacy! Every day this question of remote prognosis arises, and it may be said to have made its appearance in science with the discovery by Bouillaud of rheumatic endocarditis. When Bouillaud took up the subject he was better armed than his predecessors. Through systematic auscultation of his patients and through *post-mortem* examinations he discovered and described rheumatic endocarditis. From that time on the prognosis of rheumatic fever was a different matter. Next to—or rather before—immediate prognosis now arose the question of remote prognosis. When we are called to a case of rheumatic fever the first thing we want to know is whether the heart is affected or not. Over and beyond the present illness we see and fear possible valvulitis; we try to avert it or to arrest its progress. The prognosis for the morrow takes the lead of the prognosis of the day. Let us consider an individual who has recently contracted syphilis. Do we for a moment imagine that after we have cured the secondary manifestations all is over and that our task is at an end? So little do we think so that in our apparently quite healthy subject we go on applying the treatment, we periodically ascertain the result of Wassermann's reaction, we keep in mind the possibility of late tertiary manifestations or of vascular syphilis in the shape of aneurysm, or again of one of those redoubtable cerebro-spinal localisations which constitute the darkest chapter in the history of syphilis. What we have just said of syphilis is equally true of tuberculosis, and those two great infections share between them a very wide field in pathology. The same might be said about gout, lead poisoning, alcoholism, etc. The acute disturbance disappears, but remote sequelæ are always possible. We might almost say that nothing is forgotten in the system, and that any alteration of a tissue or body-fluid leaves its trace. The discovery of anaphylaxis by Charles Richet affords the best demonstration of this fact, and we can repeat, in the words of that distinguished scientist, that "we have a humoral personality which makes each different from other individuals: this personality of our humours is due precisely to the various ingestions and intoxications which have affected our system and left an indelible trace." If we bear these notions in mind the scope of prognosis in morbid conditions is found to be remarkably extended. The pathological life of an individual appears no longer merely as an interrupted series of isolated episodes; but we try to discern its unity, to follow its continuous course, and to take into account the sudden and sometimes final deviations and the new pathological directions that may be given to the organism by an intercurrent disease.

THE SOCIAL ASPECTS.

Let us now extend a little farther the scope of our medical foresight. Our prognosis will then include the future of the patient's descendants. I cannot dwell at length on this very important aspect of my subject, but it is evident that the possibility of inherited syphilis or tuberculosis, that the transmission of abnormal humoral conditions, such as hæmophilia and congenital hæmolytical icterus, or of family taints like those so often met with in neuropathology, do aggravate those several diseases by placing them in the group of hereditary pathological conditions. This is not all. Next to the prognosis concerning the individual and his descendants we must consider collective prognosis. This is a question of a practical order which originated quite recently with the contemporary investigations on germ-carriers. Take, for instance, a school where a case of diphtheria has broken out. Will this be an isolated case or will it become the starting-point of a small localised epidemic? The preventive measures to be taken will depend to a great extent on our judgment, and we must be guided by the direct examination of the other children in the school. We must ascertain whether amongst them there are not some who are carrying Loeffler's bacillus in their naso-pharyngeal membrane or in their tonsils. The number of these bacilli-carriers will afford us precise and valuable information. It is also to direct examination that we must turn if in a military unit, company, or squadron there suddenly appears one of those cases, often so rapidly fatal, of cerebro-spinal meningitis. In cases of this kind the systematic quest for meningococci-carriers is immediately proceeded with, and it very speedily shows whether the cases observed are sporadic or whether they are the first signs of a more or less extensive epidemic. We are thus led to form the epidemiological prognosis, which to a certain extent remains distinct from individual prognosis. Finally, above the individual, the family, and the small communities there is the race, the human species considered as a whole. Now, considering as social diseases tuberculosis, syphilis, and alcoholism, if we search for the causes of aggravation or attenuation, shall we not be reaching the highest point that can be attained by medical prognosis? How far we thus find ourselves from the old belief of the physician who, having treated his patient, thought he had done all that could be expected of him. We now feel that this would be an inadequate conception of our duty, and that not unfrequently the particular patient cannot and must not be separated from his multifarious connections with the rest of the human race. All our legislative measures in regard to disinfection and preventive vaccination find in social prognosis of disease their justification. I need not dilate on this subject in the country of Jenner, the land of efficient prophylaxis. Is it not also in this great London that as a result of the memorable work of Sir Francis Galton and his school a new science came into being—Eugenics, which held its first congress here a year ago? By improving, according to Galton's ideas, the racial qualities, both physical and mental, of the generations to come, and also by surrounding with all possible care the life of the child before and after birth, in conformity with Pinard's teaching, it seems to me that we are transferring into the domain of prophylaxis, for the greater good of the race, the notion of collective and social prognosis.

THERAPEUTICAL ADVANCES.

Does our progressively extended prognosis, based on the use of new methods and on a wider comprehension of the far-reaching effects of disease, concern facts that are always identical with themsleves? Is the prognosis of a given disease immutable? If not, why and how does it vary? To admit the immutability of medical prognosis would be to declare that our therapeutics have not progressed, Now, surely, it is not at the present time that such a dispiriting opinion could be upheld. For the last 40 years, before our very eyes, the whole of scientific and practical medicine, undergoing an incredibly rapid evolution, has been wonderfully transformed. The problems of pathogenesis, our means of clinical investigation, our methods of treatment, have all assumed a new aspect, and the prognosis of all morbid conditions has thus been deeply modified. I think it can be said that there is almost no group of diseases the gravity of which has not been notably attenuated in recent years. No doubt there are still too many cases where the physician feels powerless; but even then his lack of power is no longer so absolute. The cancer problem is always before us, but we cannot deny that, thanks to X-rays and radium, thanks to improvement in surgical *technique,* thanks also to recent advances in chemical treatment, our means of action have become less scanty and more often efficient. We may be unable to modify the prognosis of a given lesion: cerebral hæmorrhage and pulmonary embolism have lost none of their gravity. But the changes in the arterial or venous systems, which give rise to those serious accidents, are better known to us: we can prevent them or treat them with greater success. Thus even in the least favourable cases we have gained some ground.

On the other hand, we might quote many instances, especially in the domain of infections, where the prognosis of to-day is widely different from that of former times. Rheumatic fever nowadays is no longer what it was in Bouillaud's time: salicylic medication has made another disease of it. Since the introduction of Brand's treatment our typhoid patients are no longer the same, and the results already obtained by antityphoid bacteriotherapy enable us to look forward to a near and decisive advance We cannot forget what diphtheria was before the discovery of diphtheritic antitoxin by Behring and Kitasato and the splendid therapeutic deduction brought forward by Roux at the Congress at Budapest. The morbidity and mortality tables have since demonstrated throughout the world what a change has been brought about in the prognosis of diphtheria. Even the most terrible and relentless of diseases, rabies, has met its master, and the antirabic vaccination of Pasteur is perhaps the most amazing therapeutical triumph of our time.

And so each day brings with it some progress, some attenuation or modification of our prognosis criteria, some new methods of fighting disease. Armed as we are with our modern methods, having at our command mercury and arsenic in extremely active forms, do we not treat syphilis with much greater chances of success than formerly? It is not my intention to dwell on this point, but I should like to recall two other quite recent and typical instances.

Consider one of the hitherto incurable forms of trypanosomiasis—sleeping sickness. Thornton, and later Nicole and Mesnil, demonstrated experimentally the value of atoxyl in animal trypanosomiasis. Ayres Kopke, of Lisbon, applied for the first time the treatment to the human being, and since then results have been constantly improving. At the Pasteur Hospital in Paris Dr. Louis Martin has treated and followed in the last few years 40 cases of sleeping sickness, and he has kindly supplied me with his statistics. Of the first 20 cases, 11 died; of the next 10, 4 died; of the last 10 cases, none died (and yet two patients of the last series were treated more than three years after the onset of the malady). Those gratifying results are due to the improvement in the method of treatment: for large doses, separated by intervals of ten days, Louis Martin has gradually substituted smaller doses repeated more often, and success has been more complete and more lasting. We can now talk of cure in a disease the recognition of which, a few years back, was equivalent to a death sentence.

Let us now take another instance afforded by dysentery. We know that in this disease identical symptoms may be produced through different ætiological agencies and we recognise two essential forms of dysentery, one due to bacillary, the other to amœbic infection. Therapeutical advance has not been long in confirming this distinction, and to two specific infections we now oppose two specific treatments. Bacillary dysentery is almost immediately arrested and cured by specific serum-therapy as established by Shiga, Kruse, Todd, Rosenthal, Vaillard and Dopter—to mention only the early workers in the field. As for amœbic dysentery, it now possesses also its specific treatment which, although quite recent, has already proved its high value. This new treatment we owe to a British physician, Leonard Rogers, of Calcutta. For the last twelve years Rogers has devoted himself to the study of ipecacuanha medication in amœbic dysentery and to the demonstration of its preventive action in regard to liver abscess. Later, following Vedder's experiments, for ipecacuanha itself he substituted one of its alkaloids, emetine (or rather emetine hydrochloride), and he achieved the greatest success in curing quickly and entirely the intestinal and hepatic forms of amœbic dysentery. Whereas in dysenteries of equal gravity the death-rate for the cases treated with powdered ipecacuanha was 34.6 per 100, with emetine it is reduced to 8 per 100. With ipecacuanha the average duration of the treatment was 16.4 days, with emetine it has dropped to 7.2 days Here, then, is another disease, and a grave one, the prognosis of which has been entirely modified in a remarkably short time. If from infections we pass to the other groups of disease progress seems less brilliant, and the future possibilities appear to be more limited. The study of the disturbances of nutritional metabolism brings us face to face with causes more obscure, that act more slowly, and that are less favourable to therapeutical intervention. And yet, here again, our modern conquests are innumerable. Of these we may mention organotherapy, dietetic treatment, and physical therapeutics. Everywhere disease is falling back before the ceaseless efforts of therapeutics and hygiene; everywhere prognosis is undergoing an evolution and holding out fresh hopes.

The Limitations of Prognosis.

The foregoing consideration of a few of the general aspects of that great subject, medical prognosis, would appear to lead us to a very hopeful conclusion. Yet to this, as to all branches of human knowledge, there are limitations which we must not lose sight of and that are calculated to humble, if needs be, our medical pride and to bring it down to a suitable degree of modesty. What, then, are the limitations of medical prognosis? An essential distinction must here be made between theoretical and clinical prognosis. Theoretically almost everything is known to us. In a given disease we can enumerate and describe, without serious risks of omission or error, most of the complications or contingencies that may modify its course. But all that is book prognosis, far removed—unfortunately—from the living and individual prognosis, applied not to a disease but to a patient. How many unknown quantities in medical practice, and how many surprises! How little does it avail to know all the complications of typhoid fever if at the bedside of a typhoid case we cannot foresee the intestinal hæmorrhage or the perforation which, perhaps in a few hours, may endanger the patient's life. Again, for the newly infected syphilitic, for the gouty subject, for the epileptic at his first attack, for countless other sick patients of all kinds, how many uncertainties for the future! When a morbid condition begins, we know theoretically the various paths it may follow: but which one will it follow? That is the real prognostic problem, the solution of which too often eludes our grasp. Doubtless the knowledge of the inherited soil and of previous disturbances may sometimes help us; but we are ignorant of the conditions which determine the localisation of septicæmic or toxinæmic infections. No one can predict at the onset of pneumonia the pneumococcal endocarditis or meningitis that will cause death. Once the metastasis is established we cannot always appreciate the degree or the evolution of the anatomical lesion. We cannot tell whether, in a typhoid case, intestinal ulceration is growing deeper, thus threatening to cause perforation. Again, in a patient with mitral stenosis, we cannot foresee whether hæmorrhagic infarction or cerebral embolism is going to occur. And so, even in these diseases with which we are most thoroughly acquainted, prognosis remains uncertain. It is wise in theory but faltering in practice. To all those reasons for uncertainty and prudent reserve I must add one of major importance; I mean the reaction of the nervous system. I forget what statesman once said that in politics one must always reckon with the "imponderables"; surely in medical practice this remark is no less true. The nerve cell may always add its perturbing influence to all morbid processes, whether in the sense of inhibition or of stimulation; and we cannot calculate nor master at will nervous reaction, either in the sphere of motor or sensory manifestations, or of psychical phenomena, or of visceral pain. We try to redress or direct it, but it may be impossible for us to foresee its gravity or duration.

Finally, and dominating the whole question of prognosis, there remains for us to gauge the possibilities of the organism that has fallen a prey to sickness. Shall we find in it the resources necessary for overpowering disease? How much can it stand and how much can we expect of it? That is the great problem which commands and includes all the others. Are we always able to solve it? I fear not. Uncertainty and disappointment must necessarily be often our lot; but since the science of prognosis is one of the loftiest summits of medicine, we must in our ceaseless advance ever strive to behold its crowning height. Even if it remains distant and lost in the clouds, we must never despair of lessening the intervening distance. Such an ambition is a duty, and it will ever be the best stimulant to medical endeavour.

OPERATING THEATRES.

ST. MARK'S HOSPITAL.

Operation for Procidentia Recti.—Mr. Aslett Baldwin operated on a man, æt. 32, who had been admitted for prolapse of the rectum, involving all the coats of the bowel. The condition had been present for a number of years, and had been so bad as to entirely unfit the man from following any occupation. He had undergone two operations previously for the cure of the condition at a London hospital, but after a short period of relief after each operation relapse had taken place, and the patient was now as bad as ever. On examination, six or eight inches of the bowel were prolapsed through the anus, which, owing to the constant dilatation, had very little contractile power.

The patient was anæsthetised and put into the Trendelenberg position, and an incision made over the lower end of the left rectus muscle; the anterior sheath was incised and the muscle displaced outwards and the peritoneal cavity opened. A hand was introduced into the pelvis and the rectum pulled upward, thus reducing the prolapse. An incision was now made through the peritoneum and fascia of the left iliac fossa down to the iliacus muscle, and parallel to the external iliac vessels. The peritoneum and fascia were now turned sideways from the incision, thus forming two long flaps and leaving the iliacus muscle bare; the pelvic colon just above the rectum was drawn up as taut as convenient and laid in place over the bare iliacus muscle and the loosened flaps of the peritoneum and fascia sutured to it on each side, thus anchoring the bowel to the left iliac fossa for three or four inches. The peritoneum and the posterior rectus sheath were closed with a continuous thread suture. The rectus muscle was allowed to fall back into position; the anterior rectus sheath was closed with No. 2 chromic catgut, reinforced in several places with silkworm gut sutures.

The patient was sent to bed and instructions given for the foot of the bed to be raised for ten days and the bowels to be kept constipated for the same period, after which liquid paraffin was to be given by the mouth and oil enemas by the rectum to soften the fæces and prevent straining. While the man was in bed he was instructed to practice anal contractions frequently to increase the power of the anal muscle. He was kept in bed for three weeks, and when he left the hospital a few days after the sphincter power had markedly increased. He had since been up from time to time to show himself; the sphincter muscle is now practically normal, and nine months after the operation there is no sign of prolapse present, and the patient has no pain or trouble whatever with his bowels.

Mr. Baldwin said that in a bad case of this kind, which had been operated on twice previously by posterior methods, he thought the most certain and safe operation for obtaining a radical cure was the one he had just performed. He considered it was much better than suture of the bowel to the anterior abdominal wall, because this was not infrequently followed by continuous dragging pain, this being the most sensitive part of the peritoneum; and he had even known a patient insist on having the bowel freed, saying he preferred the prolapse to the constant pain. After the posterior method no pain or discomfort follow the operation.

SPECIAL REPORTS.

THE EIGHTY-FIRST ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION, HELD AT BRIGHTON, 1913.

[From Our Special Representative.]

CONCLUDING ARTICLE.

The Excursions.

After the week's strenuous work a pleasant diversion was made by the various excursions which were arranged for the Saturday. We are precluded by considerations of space from describing these interesting events in detail, but mention must be made of the enjoyable visit to Eastbourne, of the mayoral garden party at Worthing, of the notable visits to Chichester, Tunbridge Wells, and Arundel. During the week many social entertainments on a large scale were held, foremost among which may be mentioned that given by the Mayor and Mayoress of Brighton on the Wednesday evening at the Royal Pavilion, and the garden party given by the Mayor and Mayoress of Hove at St. Ann's Well Gardens on the Thursday afternoon. Both these functions were brilliant in the extreme and were largely attended. Bungalow Town, Lancing College, and Lewes were also the centres of enjoyable outings. On Friday night the President held a reception at the Hove Town Hall.

The Pathological Museum.

Though not so extensive as in some previous years, and handicapped in the absence of a catalogue, yet the Pathological Museum, housed in the Municipal Training College, contained many exhibits of real interest. Among these may be mentioned the fine collection of radiograms by Drs. W. A. Griggs, Hall-Edwards, Bythell and Barclay, W. B. Prowse, F. Bailey, and Delpratt Harris. There were some fine microphotograms by Dr. W. Wasielewski (Heidelberg) of cultures of different types of amœbæ. Dr. H. G. Adamson showed photos and cultures of sporotrichosis and tineæ. Dr. D. Walsh exhibited a series of fine coloured drawings to illustrate the connection between heart disease and certain chronic skin affections. Other dermatological studies were shown by Drs. A. Eddowes and Haldin Davis. Dr. Hans Schlimpert (Freiburg) showed a dissection and photo-diagrams of the muscles of the pelvic floor to illustrate the *technique* of the suture of the isolated and non-isolated levatores ani. A fine series of microphotographs to illustrate the surgical pathology of the prostate gland was shown by Mr. Henry Wade (Edinburgh). Dr. H. M. Galt showed various hæmatological apparatus, while some valuable specimens were lent by the Royal College of Surgeons of England, Westminster Hospital, the Royal Sussex County Hospital, and the University of Leeds.

THE SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE, LONDON, 1913.

Amid scenes of great brilliance, H.R.H. Prince Arthur of Connaught opened the Seventeenth International Congress of Medicine in the Albert Hall, London, on Wednesday, August 6th. A welcome was given to the Congress by Sir Edward Grey, and Sir Thomas Barlow then proceeded to deliver his Presidential Address, which will be found in full on p. 171. Dr. W. P. Herringham, the General Secretary, then read his report and introduced the chief representative delegates from other lands, the organist heralding the advance of each by playing a few strains of the National Anthem of his particular nation. Speaking briefly, in turn, they expressed the thanks of their Governments for the invitation to attend the Congress, and their good wishes for its success in advancing medical and surgical science.

The following is the list of the delegates:—United States of America, Dr. William Thayer; Austria, Professor Ritter von Baberler; Argentina, Dr. Eliseo Segura; Belgium, Professor Heger; Brazil, Professor Marcos Cavalcanti; China, Dr. Wu; Cuba, Dr. Aristides Agramonte; Denmark, Dr. Madsen; France, M. Landouzy; Germany, His Excellency Professor v. Schjerning; Guatemala, Dr. Azurdia; Holland, Dr. Rijnberk; Hungary, Professor Dr. Emil de Grosz; Italy, Professor Bianchi; Japan, Dr. Takamina; Mexico, Dr. Jose Larumbé; Monaco, Dr. Caillaud; Nicaragua, Dr. Alejandro Cesar; Norway, Professor Dr. Uchermann; Portugal, Dr. Luiz de Freitas Viegas; Russia, General Dr. Rapschewsky; Servia, Dr. Subbotitch; Spain, Dr. Recasius; Switzerland, Professor Sahli; Sweden, Professor Essen Möller. The President of the Permanent Commission of the Congress, Professor Waldeyer, and the President of the International Medical Press Association, Dr. Lucas-Championnière, also spoke.

The address in Medicine was delivered by Professor Chauffard later on in the day, a full abstract of which will be found on p. 173. On Wednesday evening a reception was held by the President and Lady Barlow and officials of the Congress, at the Natural History Museum, which was attended by a vast host of members and their ladies.

The address in Surgery was delivered on Thursday, August 7th, by Professor Harvey Cushing, of Harvard University, which we hope to publish in our next issue.

One of the most distinguished medical visitors was W.G.R. Professor Paul Ehrlich, of Frankfort a/M., of "606" fame. His address in Pathology, in which he dealt mainly with the modern doctrine of chemotherapy, was listened to with rapt attention. He also spoke at a combined meeting of Sections XIII. and XX. on the Monday morning in the Governors' Hall of St. Thomas's Hospital, where Professor Wassermann also made an appearance and spoke. At 2 p.m. on the same day the address on Heredity was delivered by Professor W. Bateson, F.R.S. The address on Public Health was given by the Right Hon. John Burns, M.P., President of the Local Government Board; and this was followed by the closing meeting of the Congress in the Albert Hall.

Ample accommodation was provided for the 23 Sections and the three Sub-sections in the Imperial College of Science, the Royal School of Science, the Royal Society of Medicine, St. Thomas's Hospital Medical School, the Royal College of Physicians, the Imperial Institute, the Royal Dental Hospital, and the Central Technical College, in all of which many important topics were discussed and a large number of valuable papers read.

The Medical Museum of the Congress was situated in the Imperial College of Science, and was exceedingly well arranged. The Dermatological Section (XIII.) had a separate museum of its own at St. Thomas's Hospital. A special section was organised by the International Association of Medical Museums to illustrate improvements in the various methods of preserving and exhibiting specimens, and this proved to be of very great interest.

The Medical Exhibition was situated in the large Hall of the University of London, and was probably the most extensive and important ever seen in connection with a medical congress. We hope to publish a notice of the chief exhibits in an early issue.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Aug. 9th, 1913.

Dysentery and Emetine.

Since Dr. Rogers (Calcutta) published his remarkable cures of dysentery by hypodermic injections of hydrochlorate of emetine, this treatment has been tried in France. All that Dr. Rogers claimed was fully confirmed.

There are two kinds of dysentery, as everyone knows—bacillary and amœbic. The former is treated successfully with serotherapy; but for the latter the treatment was more or less empirical; it is against this form of dysentery that emetine acts as a specific.

Amœbic dysentery, with its frequent complication, abscess of the liver, was hitherto treated by simarouba, ko-sam, and above all, ipecacuanha, to which was adjoined a surgical operation when necessary.

The frequent good results obtained from ipecacuanha encouraged Rogers, some five years ago, to apply the treatment to abcess of the liver due to amœbic dysentery; he obtained a great decrease of these abscesses in the Indian army. But the treatment was not always well supported on account of the nausea and the severe vomiting it provoked. His attention having been called to the researches of Vedder which showed that emetine, principal alkaloid of ipecacuanha, could destroy the amœba in their cultures, Rogers adopted it as a substitute for the Brazilian method and injected it hypodermically; he obtained thus a stronger action with infinitely less doses, while the mode of administration was as agreeable as it was simple. The results exceeded his expectations. Of thirty patients treated by the old method, thirteen were cured, six temporarily relieved, while eleven died. Of twenty-two patients treated by injections of emetine, twenty were rapidly and definitely cured, the remaining two succumbed.

The first in France to try Rogers' method was Prof. Chauffard, who, at the close of last year, treated a patient suffering from amœbic abscess of the liver that had opened into the lung and was expelled by expectoration in certain quantities every day for five months. Dr. Chauffard injected hypodermically one grain of hydrochlorate of emetine each day for five days; the result was not slow to appear. In a few days the expectoration of pus ceased completely, the temperature fell to normal, and the patient, who was much emaciated, gained weight; the cure was permanent. Struck by the rapidity of its action, M. Chauffard declared at the Académie de Médécine that emetine was a specific for amœbic dysentery. Immediately afterwards, M. Flandin published a similar case. The patient suffered from dysentery for three years. In 1911 the malady was complicated by an abscess of the liver that opened in the lung; for a long time the patient was thought to be tuberculous. In the summer of 1912, the abscess was incised and drained. The immediate results were excellent, and for four months the patient was considered cured. A month later, however, he recommenced to expectorate pus, and his temperature went up. A second incision was made and the abscess drained, but the condition did not improve. It was at this point that a grain and a half of emetine was injected for the first two days and one grain for two subsequent days. Immediately the temperature fell to the normal, the cough diminished and the pus was much less abundant. A month later, however, there was a slight relapse, but it yielded to a second series of injections.

Dr. Dopter, of Val-de-Grace, reported another cure of simple dysentery. It was the case of a soldier suffering from a very grave attack of dysentery, which ko-sam improved considerably at first, but soon afterwards a relapse occurred, and this time emetine was prescribed. After five injections the patient was definitely cured. Dr. Rouget published the case of a colonial officer who suffered from dysentery for ten years. After four injections of emetine the flux was cured.

It would be superfluous to continue the enumeration of other cases noted from different quarters; enough has been said to show the favour the method of Rogers has received in France in the treatment of dysentery. However, it may be well to state that hæmoptysis is equally amenable to emetine where all other treatment fails.

ERYSIPELAS

Phenic acid (liquid), 15 drops.
Essence of turpentine, 1 oz.

Apply with a brush every hour.

BUBO.

Chloride of zinc, 1 dr.
Oxide of zinc, 2 oz.
Water, 2 oz.

After evacuating the pus, the paste is applied; where there is much tunnelling, a piece of gauze coated with the paste is introduced into the cavity. Two or three dressings at four days' interval are sufficient.

GERMANY.

Berlin, Aug. 9th, 1913.

AT the Medizinische Gesellschaft, Hr. Gräfner showed a case of

OSTEITIS DEFORMANS (Paget).

He said such a case had not been brought before the Society for more than six years, when Hr. Toby showed a case. The patient shown had known no other illness than the one for which he was brought forward, with the exception of rickets and measles. There was no trace of alcholism or syphilis. The disease began about 15 years ago, when he noticed a gradual increase in the circumference of his head with diminution of the height of the body. The patient had not been addicted to having his photograph taken, so there were few records of his former appearance in existence. There were only two that showed the sharp changes that had taken place. The head at last grew to such a size that he could no longer get fitted in shops but had to have his hats made for him. At last his wife made him fur caps, which he wore summer and winter. He first came under the speaker's observation in October of last year, when the loss of height led him to suspect some affection analogous to osteomalacia. He therefore prescribed cod liver oil with phosphorus; in three months the head was 3 cm. less in circumference, and the wife had to draw in the hat. The complaints of the patient lay in obscure rheumatic pains, cough, shortness of breath, deafness for the last ten years, for the last two years disturbances of vision, and more lately occasional dyspeptic attacks with general weakness. There was bony growth in different places; the front part of the head, the temples, and the back of the head. The condition of the blood-vessels was remarkable; they could be seen, and they stood out with startling fulness when he inclined his head forwards. The head could be rotated horizontally freely, but not backwards and forwards. The inclination of the head forward was also remarkable, the kyphosis, and the outward bending of the bones of the legs. Neither the nervous system nor the thyroid showed any peculiarities. The Wassermann test was negative. As regarded the eyes, there was some atrophy of the choroid on the left, in the right, large semicircular patches of atrophy of the choroid to the right of the papilla. Angiosclerosis of the fundus on both sides. (Röntgen demonstrations shown.)

In the discussion that took place, Hr. von Hansemann said he would remark on the interesting case shown that it was difficult to distinguish Paget's disease from other enlargements. At a time some years ago, when he took an active interest in the subject, he took the trouble to go round and examine all the celebrated skulls of that description in the different collections in which they were to be seen. He very soon came to the conviction that there was no uniformity about them, and that they were caused by different diseases. He had also seen the original made use of by Paget himself when working at the subject. All these forms had a thoroughly smooth skull, as was to be seen in the most classical example in Darmstadt in the Zoological Museum; for which reason it was know to so few medical men. It was a perfectly smooth skull, and did not show what the one before them did. From the Röntgen plates he must believe that the head was a near approach to what had been described as leontiasis ossea, and which was to be seen in the Leyden Museum in Holland. It was one of the few skulls that had been observed during life. Very few such bones had been examined anatomically; most of them were of an earlier date, and their antecedence was but dark. Some of these had a knobby surface, and almost all of them had different significances. Nearly all of them were cases of multiple bony growths, which had nothing at all to do with Paget's osteitis deformans. He was of opinion that when the case came to be examined anatomically it would be found to have nothing to do with Paget's disease, but that it was one of development of tumours. He could not, of course, say positively that that would be so, but he suspected that they were growths that sprang from the periosteum. Futher knowledge must, of course, be left to the future. Nevertheless, he would still keep to the name, otherwise it would be as if something had been picked out, examined, and named, and then thrown back again into the tub. We should never get any insight into diseases in that way. On the contrary, we must differentiate still further. It was unfortunate that the disease was so rare that the individual surgeon did not often get the opportunity of seeing it. The case now shown was certainly different from that shown by Hrn. Toby Cohn, and in his opinion quite different from that originally described as Paget's disease. It was an advance to learn that there were different affections of that kind, and that they must not all be grouped together.

AUSTRIA.

Vienna, Aug. 9th, 1913.

AT the recent meeting of the Gesellschaft für Innere Medizin und Kinderheilkunde in Vienna, Dr. M. Zarfl read a paper on the subject of

PEMPHIGUS BENIGNUS CONGENITUS.

The text of the communication was furnished by the case of an infant who was ushered into the world with a bullous cutaneous eruption. There were many of the bullæ of the size of beans, or somewhat larger. The infant was first seen by the reader of the paper on the tenth day of extra-uterine existence, when there were obvious indications of the gradual absorption of the contents of some of the blebs, and distinct traces of the former presence of some which had disappeared. The majority of those traces were roundish in outline, of size about that of a small pea, faintly reddish in colour, covered with a thin and delicately wrinkled cuticle, and displaying around their margins the remains of the exuded material which had disappeared. On the hands and feet there were also some easily detached shreds of cuticle remaining as evidences of the former presence of bullæ which had disappeared; and as they dried up a new crop appeared in the neighbourhood of the traces of their predecessors. Hanging on to the fingers and toes were also to be seen large shreds of cuticle. Some obviously recent bullæ were to be seen beside those which were gradually shrinking ones; and when the little patient was seen on the following day another fresh crop had made its appearance. It could then be noticed that the recent specimens, which at first presented a fairly limpid fluid, soon were filled with turbid contents. They were each surrounded by a narrow reddish zone, and were chiefly located on the hairy scalp and on the skin of the fingers. They soon dried up and formed small, thin scabs. It is remarkable that some of the bullæ formed on the margins of the nails, and affected the bed of the same to such a degree that loss of the nail ensued in the case of several of the fingers and each of the great toes. The general condition of the infant had been good throughout, and still continues to be so. No trace of fever had developed at any time; the only constitutional change of any kind that had appeared was in the form of some slight derangements of the digestive apparatus. The eruption never gave the idea of having owed it origin to luetic infection. Not one of the numerous bullæ manifested itself as an infiltration; they all dried up and healed without any specific treatment. The Wassermann test gave negative results in both mother and infant. The case displayed throughout the characteristics of a benign congenital bullous eruption. Such cases are exceedingly rare of occurrence; up to the present date but fourteen such have been placed on record. They have all been traced backwards to intra-uterine infection. This may possibly take place through the vagina, when the birth has been postponed for a long interval after the escape of the amniotic fluid. As a result of the observations recorded after experimental inoculation of pemphigus, the conclusion has been arrived at that the period of incubation may be calculated, with fairly reliable accuracy, as averaging 36 hours. Such time of incubation, as experimentally observed, by no means tallies with that noticed in the present case—nor in those recorded by others. On the other hand, however, it is possible that the infection may have taken place through the placental vessels. Of course, the question of the mode of development of the cocci in the blood of the mother may be raised. But, however this question may ultimately be determined, neither in the present case, nor in any of those which have been placed on record by others, was there any appreciable constitutional disturbance displayed by the mother.

Dr. K. Hochsinger expressed the opinion that the rupture of the amnion and escape of the waters some days before the delivery of the fœtus would satisfactorily account for the appearance of the congenital pemphigus in this and other similar cases. The transition of the staphylococci along the placental channels—hæmic or lymphatic, or both—could not have occurred in such cases; if such course had been followed the result would have been the development of genuine pyæmic infection.

HUNGARY.

Budapest, Aug 9th, 1913.

At a recent meeting of the Budapest Interhospital Association, Dr. Sigmund Szerb read a paper on

The Relation of Meat Diet to Gout.

He said that Pflüger showed in 1900 that an exclusive diet of horse-flesh produced in dogs severe diarrhœa. He succeeded in isolating, to a certain extent, the constituent producing this deleterious effect; he found it present in the broth of the meat, could not precipitate it by means of alcohol, but could obtain an ethereal extract. At this time, Kionka showed that he could produce a genuine arthritis urica in hens by an exclusive diet of meat lasting five months. Others before this had produced gout in birds in various ways: Ebstein, by the injection of chromic acid; von Kossa, by the administration of oxalic acid, phenol, etc. The microscopic changes in the organs of hens made gouty by methods such as those of Kionka, were studied by Bannes, with the following findings: retention of urates in the liver, kidneys, spleen, and serous membranes; degenerative processes in the liver, kidneys, and spleen; necroses and cloudy swellings of the epithelia and the larger parenchymatous organs; and finally, that there is microscopically a difference between gout induced by an exclusive meat diet. The above results inspired the reader to investigate the problem as to whether any pathological changes could be found in mammals after an exclusive diet on meat. The animals experimented on were dogs. Three of these animals, after being fed for forty days on meat alone, were killed by opening the carotids and immediately subjected to autopsy. They all showed fatty degeneration of the kidneys and liver, differing qualitatively in each case. The clinical history of these animals was as follows: As regards weight, all three presented marked changes, sometimes increasing, sometimes diminishing, but the end-weight not being very different from the initial weight. The general condition was always good. The urine sooner or later contained albumin. Although no cases were found the state of the urine indicated a nephritis. The animals were markedly constipated. The autopsy revealed in all the cases an acute or a subacute nephritis, a cloudy swelling of the liver, parenchyma, and a pigment deposit in the spleen. The reader maintains that although he was not able to produce gout in dogs, as Kionka had in hens, yet his results show some analogy to the clinical and pathological manifestations of human gout, and yet he has proved a direct relationship between an absolute or almost absolute meat diet and the ætiology of gout. He alludes, in this connection, to the frequency of gout among the beef-eating Englishmen, to the increased elimination of uric acid following a superabundant meat diet, and to the fact that only a part of the uric acid is eliminated through the kidneys. The greater part is destroyed, and according to M. Kochmann, in different animals is destroyed in different parts of the body. In the dog, and perhaps also in man, a part of the uric acid is broken up in the liver, in the cow a portion is destroyed in the kidneys, and in all mammals the muscles take an important part in the destruction of uric acid. Moreover, lack of exercise would impair muscular activity in this direction. The diseased kidneys would at the same time be unable to do their share in the excretion of uric acid, with the result that this substance, accumulating in the body in certain localities, would give rise to the pathological and clinical picture of gout. A further support to this hypothesis is seen in the fact that the uric acid arthritis develops gradually, that degeneration of the liver and kidneys is found in many cases of gout, and that all those influences that would cause degeneration of the kidneys, liver and muscles would favour the appearance of gout. Of these influences may be mentioned a meat diet, either exclusive, or nearly so, chronic alcoholic poisoning, and chronic metal intoxication, particularly that of lead.

CANADA.

Toronto, July 21st, 1913.

Annual Meeting of the Canadian Medical Association.

(Concluded from page 127.)

Dr. Llewellyn F. Barker, Professor of Medicine at Johns Hopkins University, Baltimore, gave the address in medicine, which was, in fact, a lecture delivered impromptu, illustrated on the screen, regarding the nerve supply of the internal organs of secretion and of the smooth muscles. The lecture, both because it was on a subject concerning which little is known and on account of the special knowledge thereof possessed by Dr. Barker, was intensely instructive and interesting. As, however, the hall in which it was given was in darkness, it was impossible to take notes. Medical readers who may be desirous of studying Dr. Barker's views will have the opportunity of doing so at a later date, as he has promised to give for publication in the Journal of the Canadian Medical Association a written address dealing with the whole matter.

Dr. J. Alexander Hutchison, surgeon to the General Hospital in Montreal, delivered the address in surgery. He took for his text the

Present-Day Treatment of Fractures,

and passed in review the various modes of dealing with fractures practised by the surgeons of the world, and especially by the surgeons of the English speaking race. He drew largely also from his own experience in this respect, which has been a lengthy one, and owing to the wealth of material obtained at the hospital with which he is connected, has likewise been a full one. Dr. Hutchison gave great praise to the recent report of the Commission appointed by the British Medical Association to investigate the treatment of fractures, and remarked that this report had greatly increased and widened our knowledge on the subject. He went on to say that a report emanating from surgeons of the United States, while it differed from some of the conclusions reached by those responsible for the British report would still further illuminate the matter. The speaker expressed himself as in unison with the views of the framers of the American report wherein they differed from their British confrères. Dr. Hutchison was particularly emphatic in urging upon the Canadian Medical Association the duty of having defined by law the status of medical men with regard to suits for malpractice, instancing the fact that since radiography has been introduced skiagraphs of fractures have been made use of frequently, usually to the detriment of the medical profession. He pointed out the obvious truth, that no layman nor lawyer was competent to say whether a skiagraph was a true picture of existing conditions. Such persons were ignorant of the pathological aspects of the case, questions which experts alone were competent to decide.

REPORT ON THE FRIEDMANN SERUM.

In order to allay the public excitement and to afford the medical profession and the people of Canada an authoritative statement regarding the value of Dr. Friedmann's treatment, the Canadian Association for the Prevention of Tuberculosis nominated a committee of five members to study and report upon cases inoculated by Dr. Friedmann at Montreal, Ottawa, Toronto, and London. That committee afterwards added to itself those physicians who had under their observation the cases treated in those cities. The committee thus constituted begs to report that it has carefully studied the cases and histories of the patients inoculated by Dr. Friedmann, which number in all, for Montreal, 10; for Ottawa, 10; for Toronto, 81; and for London, 15. As a result of their observations from March 11th to present date (July 21st), the following conclusions seem justifiable:—(1) The inoculations have neither constantly nor frequently been followed by marked change in the clinical course of the disease. (2) The cure, or progress towards cure, claimed by Dr. Friedmann for the treatment have neither constantly nor even frequently taken place in the time during which these cases have been under observation. (3) That, upon investigation, the committee finds that the results have been disappointing, and that the claims made for his remedy by Dr. Friedmann have not been proved, and that nothing has been found to justify any confidence in the remedy. (Signed) Professor J. George Adami, Professor J. J. Mackenzie, Dr. A. H. Caulfield, Dr. G. S. Harding, Dr. John W. S. McCullough, Dr. William G. Ross, Dr. J. H. Elliott, and Dr. George D. Porter.

In this form the report of the committee appointed by the Canadian Association for the prevention of Tuberculosis to investigate into the claims made by Dr. Friedmann for his so-called cure for tuberculosis was presented to the Canadian Medical Association at its meeting recently held in London. It should be mentioned that a member of the committee, Dr. Chas. H. H. Hodgetts, of Ottawa, refused to sign the report. His decision for this course, however, was not based on reasons favourable to Dr. Friedmann's remedy, but on the contrary, his refusal to sign was because Dr. Friedmann, not having kept his promise to reveal to the committee the exact composition of his remedy, Dr. Hodgetts was of opinion that both the investigation and report were worthless.

Before the reading of the report, Dr. J. George Adami, Professor of Pathology at the McGill University, Montreal, outlined the history of the events leading up to the report. He said in part that, although guilty of much that was unethical so far as the profession was concerned, the Canadian Association for the Prevention of Tuberculosis had determined to give him a thorough test under the most favourable circumstances, in view of public opinion. He was invited to come to Canada, visited four cities, and was allowed to treat patients of his own selection. The conditions had been most favourable to Dr. Friedmann, no interference or unjust treatment being accorded him. The medical men of Canada approached him and his remedy with an open mind.

SECTION OF PUBLIC HEALTH.

This section was presided over by Dr. Helen MacMurchy, of Toronto, and its proceedings were interesting in a high degree. Medical inspection of schools was the first subject discussed. Dr. John Stewart, of Halifax, U.S., presented a paper in which, after reviewing the work being done in all the provinces, he stated that he was forced to the conclusion that the work was yet in its elementary stage. While there had been progress in the cities, owing to the efforts of the few, there was still apathy shown in the smaller places, and would be until some definite system had been worked out which would constitute a national standard. For this reason, therefore, there was need for a national public health service that could deal with such questions as immigration, sanitation of factories, control of disease, along with medical inspection of schools. The general trend of the discussion was that federal control would be the true solution of the problem of efficient public health bureaus. In the case of municipal control, local politics were certain to influence and hinder.

VENEREAL DISEASES.

Two important papers were read dealing with the problem of how to best control the spread of venereal disease. One was by Dr. A. W. Hill, Medical Officer of Health of London (Ontario), and the other by Dr. F. A. Clarkson, of Toronto. On the subjects of medical inspection of schools and of venereal disease two committees were appointed, who handed in their reports at a later session. The chief recommendation of the report on medical inspection of schools was to the effect that, for the present, the inspection of school children should be performed by an appointee of the School Board, working in conjunction with the Medical Officer of Health. However, it was eventually decided to leave the matter over for another year, and have it take a prominent place on the programme of the next convention. The main recommendation of the report on venereal diseases was that provincial Boards of Health be asked to have venereal diseases added to the list of notifiable diseases.

Dr. Llewellyn Barker, of Johns Hopkins University, Baltimore, gave by special request an address on

MENTAL HYGIENE,

a subject in which he is deeply interested—in fact, he was mainly instrumental in initiating the campaign for mental hygiene which is being so earnestly prosecuted in the United States at the present time. Dr. Barker said in part, that by the term "mental hygiene" was meant the conservation and improvement of mental health, to make men think better, act better, and become better than now. The imbecile, the criminal, the prostitute, the insane, were so because they had to be. Their minds worked that way. The majority had been born with a bad brain, and acted as their brain directed; while others, though born with a good brain, because of some deleterious act, did wrong or criminal things. Two sciences were dealing with the problem of mind improvement. One was the science of eugenics, and the other of euthenics. The advocates of the first believed largely in heredity, and were endeavouring to bring children into the world equipped with good brains. The other school believed that environment played the larger part in the development and expression of brain power. Both schools were of equal importance, and there should be no quarrel between them. Dr. Barker outlined the recent campaign in the United States inaugurated to make the public, the doctors, and the law-givers recognise the importance of the question of mental hygiene. Criminality, prostitution, imbecility and the like, were due to bad brains, and by enacting proper laws to prevent the marriage of the unfit, to prevent the spread of diseases that affect the physical well-being of the coming generation, much of the evil could be stamped out.

Dr. Alexander McPhedran, of Toronto, introduced a symposium on diseases of the stomach, and Dr. A. J. Ochsner, of Chicago, one on the thyroid.

Dr. Frank Billings, of Chicago, gave a medical clinical lecture, and Dr. John McMurphy, of Chicago, gave a surgical clinic. The city chosen for the next place of meeting was St. John, New Brunswick, and Dr. Murray Maclaren, of that city, was elected as the next president.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE CONTROL OF QUACKERY.

To the Editor of The Medical Press and Circular.

Sir,—Although under different headings, the letters of Mr. Bradburne and Dr. Dutton in your current number deal virtually with the same subject. The whole of the evils of the kinds alluded to might easily be put an end to by simple legislation. I do not refer to those extremely subtle forms of quackery which make up so small a part of the whole; I refer only to offences as coarse as the coarsest that are easily amenable to the Food and Drugs Act, the Merchandise Marks Act, and to the common law which deals with the offence of getting money under false pretences. Amendment of these laws and the appointment of a Public Prosecutor charged with their administration would serve at once to extinguish the greater part of the quack medicine trade. And, as it has been found possible easily to prevent an unqualified man from practising as a solicitor under any pretext whatever, so it cannot be difficult to make efficient the penal clauses of medical Acts, to enable the public to distinguish between legally qualified and unqualified men, or at least prevent fraudulent pretenders from assuming titles and palming themselves off upon the public as fully qualified practitioners. There exists already a great deal too much preventable human misery, and it is intolerable that increase of this should be possible to so enormous an extent, merely through lack of the simple laws which would put an end to the practices of the most cynical and cruel section of that great army of malefactors which remains parasitic upon latter-day society.

The case for medical law reform is overwhelming, and so far as the traffic in quack remedies is concerned, it has been established by the evidence before the Select Committee. It may be well to wait for publication of the report of the Committee before resuming the agitation which led to its appointment. It is the duty of the profession to force the whole question to the front and leave upon the Legislature the responsibility for the evils and abuses the extent of which is only fully known to medical men.

I am, Sir, yours truly,
Henry Sewill.

The Old Rosery,
Earlswood Common.
August 9th, 1913.

P.S.—A glaring illustration of the shameful attitude of the bulk of the newspaper Press towards quackery is furnished in the issue of one of the foremost papers of the day, which I enclose. This paper is full of reports of the Medical Congress, and contains a leader on it by its well-known medical contributor. In the previous issue appeared a report of Sir T. Barlow's speech denouncing alcoholic quack remedies. It is impossible to believe that the proprietors can be ignorant of the nature of the traffic they are abetting. On one of the principal pages alone among important matter you will see an enormous advertisement of a quack remedy, the sole potent ingredient of which is alcohol. The alcohol is in large doses. It is put forth as a cure for "all the diseases of debility, for anæmia and depression." Debility, anæmia and depression are not diseases; they are merely symptoms of many widely different maladies, and except upon an accurate diagnosis and in the hands of a skilled physician, alcohol must prove a poison in most of such conditions, and, if long continued, a deadly poison in many of them. The proprietors of this paper, like all their class, assume the *rôle* of guardians of the welfare of the people, defenders of the national honour. The simple public take the appearance of advertisements in papers of this class as a guarantee of good faith; and, unless the advertisements were followed by an enormous sale, it would be impossible for the nostrum-monger to support the vast expenditure I endeavoured to expose this scandal in my evidence before the Select Committee. The report of the Committee, it is stated to-day, is put off now till next session. The prospect of legislation seems remote.

A DOCTOR'S WIFE ON DRESS.

To the Editor of The Medical Press and Circular.

Sir,—The question of women's health is closely wrapped up in their dress. Many simple women, naturally robust, are unconsciously handicapped by their anti-hygienic habiliments. Many foolish, delicate women are unwittingly kept on the verge of chronic invalidism by the same cause. The subject cannot be so freely discussed anywhere as in a medical paper. I therefore was glad to see the letter of a "Doctor's Wife" in your last number. I believe that every intellectual, educated doctor's wife (and are they not nearly all intellectual and educated?) reads the medical papers. I rarely miss. I can say the same of the majority of my acquaintances. Nearly all doctors are married. There must be more than twenty thousand of us in the Kingdom. If we could be brought together we might form a lump big enough to leaven the mass of of our fellow-countrywomen. Some concerted propaganda or action might be started, although dress reform leagues have hitherto made such a poor show. I agree with everything that a "Doctor's Wife" says. She seems equally observant and wise. Many of us will envy the literary skill with which she expresses herself. I agree that the first thing needed is emancipation from the thrall of the Parisian man-milliner. He is at the same time inartistic, immodest, and unhygienic. Not to go further back than the middle of the Nineteenth Century, the fashions imported from France have all been of this character. We have had the crinoline, the bustle, the pannier, and no end of different forms of corsets to distort the natural form, the chignon and head-dresses, bonnets, and hats often more useless, hideous and barbarous than the ornaments of a Zulu bride. And now we have the semi-nude. The semi-nude and the nude are fitted for the tropics alone, and can be displayed with modesty only by natives who are to the manner born. From toe to top—from the thin shoe with the preposterous high heel and the diaphanous stocking, to the grotesque hat that crowns the costume, it is all wrong from the point of view of art, utility or health.

I am, Sir, yours truly,
A Consultant's Wife.

London, W.
August 8th, 1913.

To the Editor of The Medical Press and Circular.

Sir,—The nude is not necessarily either indelicate, indecent, or lewdly suggestive. Witness the Greek masterpieces. But try the experiment of putting an open bodice on the Venus of Milo, or a transparent gown on the Medici, and note the effect. The Greek expresses absolute purity. On the other hand, with the exception, perhaps, of that of Rodin and one or two others, the nude work of modern French sculptors seems inspired by models selected from the demi-monde or prostitute class. See, for example, the dancing figure on the Grand Opera building, and the figures at the base of the Gambetta monument. French art is decadent, and expresses this decay in dress throughout. The climate neither of France nor of these islands calls for nakedness, and the exposure which is now the fashion is fitted only for those women whose stock-in-trade is formed by their bodies. I thank a "Doctor's Wife" for her letter of protest. I am in the same position, albeit a student and follower of art as well, and I can support her argument from that point of view, whilst appreciating the question fully in its hygienic aspect.

I am, Sir, yours truly,
Doctor's Wife No. 2.

August 9th, 1913.

OBITUARY.

DR. G. MIDDLEMISS, OF DARLINGTON.

We regret to record the death of Dr. George Middlemiss, M.D., V.D., which has taken place at his residence, Wear Court, Grange Road, Darlington. By this sad event Darlington loses a citizen who filled an honourable position in the town for about four decades, for three of which he held office under the Board of Guardians, and who for 15 or 16 years held a commission in the local Volunteer force, taking a very keen interest in ambulance work, both in connection with that force and in civil life.

Dr. Middlemiss, who was 68 years of age, was a native of Sunderland, and came to Darlington at the beginning of the '70's, having qualified at Glasgow in 1871. He became M.D.Durham in 1889. He joined the Volunteer force in 1861, and was a member of the 3rd Vol. Batt. D.L.I., and as such was present at the great Volunteer review in 1862 at Edinburgh, when her late Majesty Queen Victoria reviewed the troops. He was commissioned as acting surgeon in September, 1882, Captain in 1889, Major in 1897, Surgeon-Lieutenant-Colonel in September, 1902, when the Volunteer Decoration was conferred upon him, and retired with the rank of Surgeon-Colonel in 1907. He was also granted the commission of Surgeon-Captain in 1893, promoted Surgeon-Major in 1894, and Surgeon-Lieutenant-Colonel in 1902 in the Army Medical Reserve of Officers, so that he had two commissions in H.M. Forces of the same rank. He instructed the first lot of regimental bearers who in 1884 obtained the Army Ambulance certificate, these men belonging to the Darlington detachment, this battalion being the first in the country to obtain the certificate and permission to wear the Geneva Badge on the arm.

Dr. Middlemiss was for 30 years Medical Officer to Darlington Workhouse and poor law doctor for Darlington, and during that time paid most careful and conscientious attention to all his poor patients, by whom he was held in affectionate esteem for his great kindness. It was to them a matter of great regret when he resigned the position a year or so ago. He was a very keen Freemason, taking great interest in the duties of all the various offices he filled, and attaining high rank in the province, being a past-master of the Universities Lodge, Durham, and of the Marquess of Ripon Lodge, Darlington, and was a P.P.J.G.W. of the Province of Durham, having been appointed to that elevated office in the craft in 1901. He was also a member of the Hospital of St. John of Jerusalem in England, and gave a great deal of his time to the service of that Order as instructor or examiner of ambulance classes.

Dr. Middlemiss at one time held office as churchwarden at St. Cuthbert's. In politics he was a staunch Conservative.

He leaves a widow, a daughter, and four sons to mourn his loss, and to them will be extended the deep sympathy of a large circle of friends and acquaintances.

A bed in the Dreadnought (Seamen's) Hospital, Greenwich, endowed by Brigade-Surgeon John Law, M.D., I.M.S., for the use of natives of India, at a cost of £1,000, was formally opened last week by Mr. Percival Nairne, Chairman of the Committee of Management.

REVIEWS OF BOOKS.

MIDWIFERY. (a)

When a book reaches the sixth edition a review as to its value is superfluous. Dr. Jellett is to be congratulated upon the excellent standard maintained in his work and the manner in which he has kept each succeeding edition in touch with the advances in the science of obstetrics. The present volume is printed on larger paper, and the type is more spaced, which makes it more pleasant to read. Many of the illustrations are larger and greatly increased in value, in that filled-in drawings have largely replaced the outline illustrations of the previous editions. The letterpress is extensively revised so as to meet the present-day practice of midwifery. Some changes have been made in the order of subjects, with the result that the sections come in better chronological order. For instance, the decidua is dealt with in connection with the ovum instead of in the chapter on "Pregnancy and Its Phenomena." Hyperemesis is rightly included amongst the toxæmias instead of the disorders of pregnancy. In dealing with eclampsia, it is interesting to note that the relative frequency is given as .38 instead of .28 as in the previous edition. The presence of undigested food in the digestive tract is added as a predisposing cause, and the whole treatment revised so as to conform with that adopted at present in the Rotunda.

Cæsarean section is added to the modes of treatment for placenta prævia, but is not advised except in very exceptional cases of central placenta prævia, nearly at term, and with a living child.

Vaccine treatment is more fully discussed, and the manner in which autogenous vaccines may be obtained is described. The operation of ligation or removal of septic thrombotic veins is referred to, as is also extra-peritoneal Cæsarean section. A complete change is shown in the omission of symphysiotomy, which is not described in the chapter on operations, and is also omitted from the alternative methods of treatment which may be adopted in the minor degrees of contracted pelvis.

The book is an improvement on the last edition from the better type and illustrations, and it has fully advanced with the times. It is to be strongly recommended to those for whom it is written—practitioners and students—as a ready and handy volume in which to find the proper and present-day methods of dealing both with normal and abnormal obstetric cases.

DUODENAL ULCER. (b)

Two years have elapsed since we reviewed the first edition of this work of Sir Berkeley Moynihan, which we characterised at the time as an excellent and exhaustive monograph on duodenal ulcer, by one whose surgical achievements in the treatment of the condition entitled him to speak with authority. The second edition, now before us, has been enlarged by about 100 pages and fifteen illustrations. The writer has not made many alterations in the text, but has greatly enhanced the value of his work by the fresh material he has introduced. This chiefly deals with the differential diagnosis of duodenal ulcer and the results of the X-ray examinations of the stomach after a bismuth meal.

The author is not quite so dogmatic about the certainty of correct diagnosis in chronic duodenal ulcer. From the experiences he relates one sees that some little point in the patient's anamnesis missed or not sufficiently weighed may lead to error. But of 100 consecutive cases of operation in which this diagnosis had been made, two proved to be of gallstones and one of gallstones and appendicitis. Another pitfall is ulceration of the stomach. Discussing a cure of the latter, where the symptoms were mistaken for duodenal ulcer, we find, on page 142, "the only discrepancies between the story given by him and the typical history, as I have related it, were that the seasonal variations had never been observed, that the pain in the back had been unremitting, and that the symptoms had been present without intermission for over three years." In Chapter V. the writer has added a section on the treatment of melæna neonatorum by the direct transfusion of blood. This, according to the authorities he quotes, is almost a specific remedy for melæna and other hæmorrhages due to acute anæmia in the newly born, a condition that up to the present has baffled all hope of successful treatment.

(a) "A Short Practice of Midwifery, embodying the Treatment adopted at the Rotunda Hospital, Dublin." By Henry Jellett, B.A., M.D., F.R.C.P.I., Master, Rotunda Hospital. Sixth edition, revised, with four coloured plates and 207 illustrations. Pp. 619. London: J. and A. Churchill. 1913.

(b) "Duodenal Ulcer." By B. G. A. Moynihan, M.S.(Lond.) F.R.C.S. Second Edition, Enlarged and Illustrated. Pp. 486 Philadelphia and London: W. B. Saunders Co. 1912. Price 21s. net.

There is a new chapter on jejunal and gastro-jejunal ulcer. Among other cases the author reports three which came under his care, in one of which he was responsible for the original operation. He describes and illustrates the treatment by excision of the parts. The *technique* of gastro-enterostomy and the local surgical treatment of the ulcer are fully and lucidly described in another chapter.

Throughout the text there are numerous clinical histories, in small print, of personal cases and those published by others. These records are interesting and essential in a work of this kind. The complete notes of the 305 cases operated on by the author are contained in the two appendices, for which Mr. Harold Collinson is responsible. We extract from the latter's "Detailed Statement of Cases Operated On":—"In one instance, case 305, the last of the series, a fatal result occurred. The patient, who was extremely ill and anæmic before operation, died of sudden cardiac failure on the thirteenth day. At autopsy no lesion other than fibroid degeneration of the myocardium could be found to account for death. Between this case and the last fatal case of the previous series (case 112), 192 consecutive operations had been performed without a death." Of 302 cases, 250=82.78 per cent. were cured, 21=7 per cent. improved, and 5=1.65 per cent. died as a result of operation. Comment is superfluous. We congratulate Sir Berkeley Moynihan. His book is worthy of his excellent results, and in every way must appeal to the surgeon, if not to the physician also.

TUBERCULOSIS. (*a*)

This is a very compact and complete volume dealing with all forms of tuberculosis, and is translated from the second German edition by Dr. G. B. Hunt, and should prove of the greatest use to all British medical readers, but more especially to those holding tuberculosis posts, either in sanatoria or in dispensaries.

The subject is treated from a pathological standpoint, and the old distinction of "medical" and "surgical" tuberculosis is discarded. The book has been received with great favour in the land of its birth, as evidenced by the fact that a second edition was necessary within the space of eighteen months. The book contains fifteen chapters, of which the first deals with the ætiology of tuberculosis, the second with pulmonary tuberculosis, and the third with tuberculosis of the pleura. The two latter occupy nearly half of the book, and afterwards follow portions devoted to the digestive organs, the uro-genital organs, the vascular and lymphatic systems, the skin, organs of locomotion, nervous system, eye, ear, miliary tuberculosis, scrofula and tuberculosis in children form the remaining part of the volume.

A valuable part of the work is that in which the authors consider the appropriate tuberculin treatment along with the text in each form of the disease, and for which further aid is to be given in a subsequent edition on "Tuberculin in Diagnosis and Treatment," but in the X-ray diagnosis of tuberculosis the vertical position of the heart, on which radiographers place so much importance, has been omitted. The authors' graphic representation of lung signs is described and illustrated, as also are plates from Cornet's work on the pathological anatomy of tuberculosis of the lungs and larynx, and Robert Koch's immortal record on bacterial diagnosis in his "Ætiology of Tuberculosis."

Altogether this is a splendid work, and the authors are to be congratulated on producing such an authoritative, carefully elaborated and excellent system of condensation, which, together with the absence of unessentials, should make it a helpful guide to all associated in any way with the problem of tuberculosis.

TUMOURS OF THE LUNGS. (*a*)

It is now many years since Stokes devoted a brief chapter in his "Diseases of the Chest" to cancer of the lung, and it is curious how little has been systematically written on the subject since. There have been, indeed, occasional references in periodical literature, though the disease is still held a rare one. Dr. Adler has been able, with much research, to collect only 374 cases of primary carcinoma of the lung. Of these he gives notes in his recent book. He has also collected notes on reported cases of primary sarcoma, of doubtful cases of malignant disease, and of miscellaneous tumours of the lungs. The tables dealing with these cases constitute two-thirds of his book, and will prove useful to anyone wishing to study the subject. The first third of the book is taken up with introductory chapters and some remarks on the pathological and clinical aspects of the disease. It would appear that the great majority of primary cancers of the lung originate in the mucous membrane of the bronchi. On the clinical side the author adds but little to what Stokes taught eighty years ago. Professor Adler's plates representing microscopic appearances are excellent, but those representing gross specimens hardly serve as illustrations. After prolonged study we have been unable to form any conception of what the coloured frontispiece is intended to represent.

INFANT FEEDING. (*b*)

This book represents an attempt to make clear the scientific processes which underlie infant feeding, and to reduce these principles to everyday practice, so that they can be grasped by the ordinary practising physician. It is based on a course of lectures given to the students of Rush Medical College.

The book is divided into four parts. Part I. deals with "the fundamental principles of infants' nutrition." Part II. deals with "the nourishment of the infant on the breast." Part III. deals with "artificial feeding." Part IV. deals with "nutrition under other conditions." In this last part are to be found chapters dealing with such subjects as "The premature infant," "The exudative diathesis," "The spasmophilic diathesis," "The nervous infant," etc.

The author has drawn largely on the works of Finkelstein, of Czerny and Keller, Meyer, Uffenheimers, Freund, etc., and the result is an eminently practical and readable book.

NEW BOOKS AND NEW EDITIONS.

The following have been received for review since the publication of our last monthly list:—

Arnold, Edward (London).
  A Text-book of Surgery for Dental Students. By G Percival Mills, M.B., B.S.Lond., F.R.C.S., and Humphrey Humphreys, M.B., Ch.B., B.D.S.Birm., L.D.S.Eng. Pp. 340. Price 12s. 6d. net.

Baillière, Tindall, and Cox (London).
  Acute Abdominal Diseases, including Abdominal Injuries and the Complications of External Hernia. By Joseph E. Adams, M.B., M.S.Lond., F.R.C.S.Eng., and Maurice A. Cassidy, M.A., M.D., B.C.Cantab., F.R.C.P.Lond. Illustrated. Pp. 571. Price 12s. 6d. net.

Bale, John, Sons, and Danielsson, Ltd. (London).
  Studies on the Influence of Thermal Environment on the Circulation and the Body-Heat. By Edgar R. Lyth, M.B.Durham, M.R.C.S.Eng. Pp 72. Price 2s. 6d. net.
  Clinical Surgical Diagnosis for Students and Practitioners. By F. de Quervain. Translated from the Fourth Edition by J. Snowman, M.D. Pp. 779. Price 25s. net.

(*a*) "A Clinical System of Tuberculosis." By Drs. Baudelier and Rœpke. London: Bale, Sons and Danielsson, Ltd.

(*a*) "Primary Malignant Growths of the Lungs and Bronchi. A Pathological and Clinical Study." By J. Adler, A.M., M.D. Pp. xii. and 325. Illustrated. New York: Longmans, Green and Co. 1912. Price 16s. net.

(*b*) "Infant Feeding." By Clifford G. Grulee, A.M., M.D. Pp. 295 Illustrated. Philadelphia: W. B. Saunders Company. 1912.

Field Service Notes for R.A.M.C. By Major T. H. Goodwin, R.A.M.C. Price 2s. 6d. net.
The Hunterian Oration. Delivered at the Royal College of Surgeons, 1913. By Sir Rickman J. Godlee, Bart., P.R.C.S., B.A., M.S., M.D.Dub., Hon. Causa, Hon. Surgeon in Ordinary to the King. Price 2s. 6d. net.
Epidemic Infantile Paralysis. By Prof. Paul H. Romer. Translated by H. Ridley Prentice, M.D., B.S.Lond., M.R.C.S. Illustrated. Pp. 208. Price 7s. 6d.

CHEMIST AND DRUGGIST, THE, London.
Provincial Hospital Pharmacopœia. Pp. 288.

CHURCHILL, J. AND A. (London).
Surgical Pathology and Morbid Anatomy. By Sir Anthony A. Bowlby, C.M.G., F.R.C.S. Sixth Edition. Edited with the assistance of Dr. F. W. Andrewes. Pp. 650. Price 10s. 6d. net.
Lang's German-English Dictionary of Terms used in Medicine and the Allied Sciences. Second Edition. Edited and revised by Milton K. Meyers, M.D. Philadelphia, etc. Pp. 564. Price 18s. net.
Obstetric Aphorisms for the use of Students. By J. G. Swayne, M.D. Eleventh edition revised and edited by W. C. Swayne, M.D., etc., etc. Pp. 216. Price 3s. 6d. net.
The Healthy Marriage. By G. T. Wrench, M.D., B.S.Lond. Pp. 300. Price 3s. 6d. net.
Dr. Chavasse's Advice to a Mother. Seventeenth authorised edition revised by T. D. Lister, M.D. Pp. 340. Price 1s. 6d. net.
Book for Mothers on the Management of Children in Health and Disease. By A. M. Usher, with introduction by Francis B. Rutter, M.D., F.R.C.S. Pp. 106. Price 1s. net.

DENT, J. M., AND SONS, LTD. (London).
A Plea for the Thorough and Unbiassed Investigation of Christian Science. By An Enquirer. Pp. 199. Price 1s. net.

EWART, SEYMOUR AND CO., LIMITED (London).
Protein and Nutrition: An Investigation. By Dr. M. Hindbeck. Pp. 201. Price 7s. 6d. net.

CORNISH BROS. (Birmingham).
Contributions to Practical Medicine. By Sir James Sawyer, M.D. Fifth Edition. Revised. Pp. 410.

FORSTER GROOM AND CO., LIMITED (London).
Hints for Regimental Medical Officers of the Territorial Force. By Captain M. F. Grant, R.A.M.C. Pp. 39. Price 1s. 6d.

FROWDE, HENRY, AND HODDER AND STOUGHTON (London).
Cancer of the Breast. By Charles B. Lockwood, F.R.C.S. Pp. 234. Price 10s. 6d. net.
Manual of Bacteriology. By R. Muir, M.A., M.D., and J. Ritchie, M.A., M.D. Sixth Edition. Illustrated Pp. 736. Price 10s. 6d. net.
The Principles and Practice of Medical Hydrology. By Fortescue Fox, M.D.Lond. Pp. 295. Price 6s. net.
Surgical Experiences in South Africa, 1899-1900. By G. H. Makins, C.B., F.R.C.S. Second Edition. Pp. 504. Price 10s. 6d. net.

KIMPTON, HENRY (London).
Asthma and its Radical Treatment. By James Adam, M.A., M.D., F.R.F.P.S. Pp. 184. Price 5s. net.

LEWIS, H. K. (London).
The Bradshaw Lecture on the Diagnosis and Treatment of Incipient Pulmonary Tuberculosis. By David Bridge Lees, M.D.Cantab., F.R.C.S.Lond. Pp 116. Price 5s. net.
The Place of Climatology in Medicine being the Samuel Hyde Memorial Lectures. By William Gordon, M.O., M.D., etc. Pp. 62. Price 3s. 6d. net.

LIPPINCOTT, J. B., Co. (Philadelphia and London).
Mechanical Treatment of Abdominal Hernia. By William Burton De Garmo, M.D. Illustrated. Pp. 147. Price 6s. net.
International Clinics. A Quarterly of Illustrated Clinical Lectures. Edited by Henry W. Cattell, A.M., M.D. Vols. 1 and 2. Twenty-third series. 1913. Price 35s. net per year. Four volumes.

LONGMANS, GREEN AND CO. (London).
London Public Health Administration. By W. M. C. Wanklyn, B.C.Cantab., etc., etc. Pp. 59. Price 2s. 6d. net.

REBMAN, LTD. (London).
A Course in Normal Histology. By Rudolf Krause. Translated by P. J. R. Lehmahl, M.D., New York. Illustrated. Pp. 86. Price 5s. net.

W. B. SAUNDERS COMPANY (Philadelphia).
Diet Lists of the Presbyterian Hospital, New York City. By Herbert S. Carter, M.D. Pp. 129. Price 5s. net.

SCOTT, GREENWOOD AND SON (London).
Disinfection and Disinfectants. By M. Christian Translated from the German by Charles Salter. Pp. 107. Price 5s. net.

SMITH, ELDER AND CO. (London)
How to Diagnose Smallpox. By W. M. C. Wanklyn, B.A.Cantab., M.R.C.S., L.R.C.P., D.P.H. Illustrated. Pp. 104. Price 3s. 6d. net.

SOCIETE D'EDITIONS SCIENTIFIQUES ET MEDICALES. (Paris.)
Therapeutique des Cliniques de la Faculte de Paris. Edited by M. Laignel-Lavastine. Vol. 1. Pp. 739.
Precis d'Anesthesie Locale. By G. Piquand. Pp. 263.
Archives Urologiques de la Clinique de Necker. By F. Leguen. Pp. 120.

THE NATIONAL ANTI-VACCINATION LEAGUE (London).
Leicester: Sanitation versus Vaccination. By J. T. Biggs, J.P. Pp. 784.

WILEY, J., AND SONS (New York). CHAPMAN AND HALL (London).
Resuscitation from Electric Shock, Traumatic Shock, Drowning, Asphyxiation from any Cause. By C. A. Lauffer, A.M., M.D. Pp. 47. Price 2s. net.

WOMEN'S INDUSTRIAL COUNCIL (London).
How to Take Care of the Sick at Home. By W. and S. Rintoul, with preface by Sir Victor Horsley. Pp. 30. Price 1d.
How to Take Care of the Baby. By Selina F. Fox, M.D., B.S., with preface by Eric Pritchard, M.A., M.D. Pp. 25. Price 1d.

MEDICAL NEWS & PASS LISTS.

The XVIIth International Congress of Medicine.

THE Permanent Commission of the Seventeenth International Congress of Medicine has announced that the next Congress will take place in Munich in 1917, under the presidency of Professor Friedrich von Müller, of Munich.

It is further announced that the Congress Prizes have been awarded as follows:—

The Moscow Prize, to Professor Charles Richet, of Paris, for his work on Anaphylaxis.

The Paris Prize, to Professor A. von Wassermann, of Berlin, for his work on experimental therapy and on immunity.

The Hungary Prize, to Professor A. E. Wright, of London, for his work on Anaphylaxis.

Royal College of Surgeons in Ireland—Post-Graduate Course.

THE autumn post-graduate course of the Royal College of Surgeons in Ireland has again been rearranged, in accordance with the suggestions of a number of those interested. It has been found in practice, that general practitioners, especially those in country districts and small towns, are usually very desirous of obtaining the benefits of post-graduate courses, but are unwilling to devote three weeks of their annual holiday to a post-graduate course as usually arranged. The Committee, therefore, with this in view, have divided the course, as last year, into three sections: Medical, lasting one week; Special, including Gynæcology, three days; Surgical, ten days; so that one may take either the whole course or any part of it, and if time is limited one could take a different section each year with very little extra expense and without trespassing too much on one's annual holiday. The course begins on 22nd September and lasts till 13th October, 1913.

The Caledonian Medical Society.

THE thirty-third annual meeting of the Caledonian Medical Society was held on Monday last at King's College, Strand, under the presidency of Dr. M. Cameron Blair, of Northern Nigeria. This was the fifth occasion on which the annual meeting had been held in London, the last being ten years ago. Since then the Society—composed of Scottish medical men—has made great strides. There were two presentations—a gold badge of office for the President, given by twenty-one past holders of the chair, and a curiously-formed silver, oak and jewelled loving-cup by the members of the Society.

Colonel Macdonald, of Inverness; Dr. W. A. Macnaughton, of Stonehaven; and Dr. D. Rorie, of Cults, had been responsible for the carrying out of the details of the cup, which is a replica of one preserved in Dunvegan Castle, dated 1493, and referred to in Sir Walter Scott's "Lord of the Isles." The original, known as the Dunvegan Cup, is regarded as one of the greatest curiosities in Scotland.

The President delivered an address on David Livingstone, whom he described as one of the most noted of Caledonian medical men.

At the annual dinner at the Hotel Cecil Dr. M. Cameron Blair presided over a distinguished and representative company.

King's College Hospital Medical School.

In view of the increased amount of instruction which is to be given in the new hospital at Denmark Hill beginning on October 1st next, the following additional appointments have been made:—

Norman Dalton, M.D., F.R.C.P., Lecturer on Medicine; F. W. Tunnicliffe, M.D., M.R.C.P., J. Charlton Briscoe, M.D., M.R.C.P., and H. W. Wiltshire, M.A. M.D., M.R.C.P., Lecturers on Practical Medicine; F. W. Tunnicliffe, M.D., M.R.C.P., Lecturer on Therapeutics and Applied Pharmacology; G. Lenthal Cheatle, C.V.O., C.B., F.R.C.S., joint Lecturer on Surgery; T. Percy Legg, M.B., M.S., F.R.C.S., Lecturer on Operative Surgery; Hugh Playfair, M.D., M.R.C.P., F.R.C.S., Lecturer on Gynæcology; H. Willoughby Lyle, M.D., B.S., F.R.C.S., Lecturer on Practical Ophthalmology; G. J. Jenkins, M.B., C.M., F.R.C.S., Lecturer on Practical Otology; J. F. W. Silk, M.D., Lecturer and Instructor in Anæsthetics; G. B. Flux, M.D., Instructor in Anæsthetics; P. B. Ridge M.B., B.Ch., Lecturer on Morbid Anatomy and Histology, and Curator of the Museum; Robert Knox, M.D., C.M., Teacher of Radiography.

The following additional appointments have been made to the staff of King's College Hospital:—Hugh Playfair, M.D., M.R.C.P., F.R.C.S., promoted to the position of Obstetric Physician; Sir Ronald Ross, K.C.B., M.D., D.Sc., F.R.S., to be Physician for Tropical Diseases; Robert Knox, M.D., C.M., to be Radiographer; R. W. A. Salmond, M.D., M.Ch., D.P.H., to be Assistant Radiographer; E. B. Clayton, M.B., B.S., to be Medical Officer in charge of the Department of Massage and Electro-Therapeutics; G. W. Shore, M.R.C.S., L.R.C.P., to be Sambrooke Medical Registrar; H. P. Ashe, M.R.C.S., L.R.C.P., to be Resident Casualty Officer.

SCHOLARSHIP AND PRIZE EXAMINATIONS, 1913.

Senior Scholarship, Mr. C. F. Hacker; Medicine Prize, Mr. A. E. Panter; Obstetric Medicine Prize, Mr. F. H. Mosse; Forensic Medicine Prize, Mr. F. H. Mosse; Todd Prize, Mr. E. W. Carrington; Clinical Surgery Prize, Mr. F. H. Mosse; Tanner Prize, Mr. E. W. Carrington; Diseases of Children, M. C. F. Hacker.

Attack on a Prison Medical Officer.

OUTSIDE Holloway Prison last Saturday an attempt was made to attack Dr. Pearson, the Medical Officer of Holloway Prison, by four militant suffragists. Dr. Pearson was crossing the road to the prison, when the four women, who had been waiting outside, dashed at him, one of them producing a heavy ivory handled riding crop, which she had concealed beneath her cloak. Before the women could succeed in their attempt to assault the doctor, however, the police on duty outside the prison interfered. At the same moment four or five women—not suffragists—who had just been discharged from prison, came out of the gates; they at once took the doctor's part, and with their assistance and that of the police Dr. Pearce was able to enter the prison in safety. The discharged prisoners then attacked the four suffragists, who eventually took refuge on a passing omnibus. Later on in the day, two windows in the house in Hilmarton Road, N., of Dr. Pearson were smashed by suffragists, who threw bricks through the panes. No arrests were made.

A New Medical Scholarship.

THE Corporation have decided to found in connection with the City of London School a medical scholarship of the value of £40 a year for four years, tenable at St. Thomas's Hospital, on the understanding that a similar scholarship is provided by the governing body of the hospital.

Death after an Injection of Salvarsan.

AN inquest was held at Westminster last week on the body of Mr. John Rogers Vinton Gilliat, aged 42, an American, who died at his apartments in Eaton Terrace, Eaton Square.

Francis August, in whose house Mr. Gilliat was staying, stated that on Friday and Saturday he was very queer. There was something the matter with his throat. On Saturday morning he summoned a doctor by telegram. He appeared to be in great pain, and he became much worse before the doctor came.

Mr. Cyril Nitch, surgeon, of Harley Street, said that Mr. Gilliat consulted him first in November, 1912. He said he had been suffering for 24 years and had been treated by doctors on the Continent, having had all the recognised treatment by drugs. He had had a recurrence of his trouble, and had been advised to have an injection of salvarsan. After satisfying himself that Mr. Gilliat was a suitable subject, he made the injection on January 6th, using six grains of the fluid. A full dose was nine grains, but he never gave a full dose of that particular drug. A few hours after the injection the patient left the home in good condition. On July 25, when he next saw Mr. Gilliat, he said he felt better than he had felt for years. There was, however, something wrong with his tongue, and the witness told him he could choose between treatment by drugs or another injection. He eventually decided to have another injection. The witness examined him, and on July 29th gave him another injection of six grains. No bad symptoms followed, and the next day Mr. Gilliat said he was perfectly well. On the morning of August 2nd he found him in bed. He was restless and very cold, and complained of pains everywhere. The witness called in another doctor, infused the patient with saline, and injected strychnine, morphia, etc., to allay the pain. He and the other doctor remained with him all day, and he also called in Dr. Willcox, the expert in poisons, who said he had no further advice to give regarding the treatment. That was between 4.30 and 5.30 p.m.; death took place at 8 p.m. He thought that death was due to delayed poisoning, caused by the arsenic in the injection. The case was a curious one, as there were no symptoms of arsenical poisoning until three days after the last injection.

Dr. R. S. Trevor, who made a *post-mortem* examination, attributed death to heart failure while the patient was suffering from general blood poisoning. Having heard Mr. Nitch's evidence, he was of opinion that the blood poisoning was due to the injection of salvarsan, which contained arsenic—arsenical poisoning.

The jury returned a verdict of "Death by misadventure," and expressed the opinion that Mr. Nitch had acted in a proper and skilful manner.

Small-Pox in Sydney, New South Wales.

WE are requested to announce that the Agent-General for New South Wales has received the following telegram, dated Sydney, August 2nd, from the Premier of the State:—"The Director-General of Public Health reports that the small-pox epidemic now existing in Sydney is of very mild type, similar to that in Canada. There have been 400 cases, no deaths, and no patient has been dangerously ill."

Royal Army Medical Corps.

THE War Office has issued the following list of successful candidates, arranged according to merit, for commissions in the Royal Army Medical Corps at the competition held in London during July, for which 21 candidates entered:—E. W. Wade, M.B., B.S. Lond., B. Woodhouse, M.R.C.S., L.R.C.P.Lond., W. K. Morrison, M.B., Ch.B.Edin., E. Percival, M.B., Ch.B.Edin., H. C. D. Rankin, M.B., Ch.B. Glasg. Messrs. Woodhouse, Morrison and Percival being in possession of certificates obtained in the Officers' Training Corps, were awarded service marks under paragraph 71 of the Regulations for the Officers' Training Corps.

London School of Tropical Medicine.

THE following candidates have passed the examinations during July, 1913:—With distinction: E. C. Perkins, M.D., Col. U.S.A., H. H. D. Knapp, M.D., Capt. I.M.S., C. N. Davis, M.B., B.S.Lond., D.P.H., J. E. H. Gatt, M.R.C.S., L.R.C.P., D.P.H., Capt. R.A.M.C., W. E. Glover, M.B., Ch.B.Aberd. Ordinary pass: J. Hannington, M.R.C.S., L.R.C.P., Mrs. D. Parsons, M.D.Edin., W. L. Webb, M.R.C.S., L.R.C.P., G. Dunderdale, M.D.Lond., M.R.C.S., B. B. Paymaster, L.R.C.P., M.R.C.S., Capt. I.M.S., R. Trudinger, M.D., B.S.Adelaide, W. E. S. Digby, M.R.C.S., L.R.S.C., H. North, M.R.C.S., J. A. Valentine, M.D., R. P. Ratnaker, L.M. and S., G. da Silva, L.R.C.P., L.M. and S., H. H. Stewart, M.B., Ch.B.Edin., P. J. Zepeda, M.D., I.M.C., J. M. Cure, M.B.Lond., A. Robertson, M.B., Ch.B., D.P.H., E. V. Smith, L.R.C.P., L.R.C.S.Edin., C. E. F. Mouat-Biggs, M.R.C.S., H. E. Fretz, L.R.C.S. and P.Edin., J. B. Dalzell Hunter, M.B., Ch.B.Glasg., Capt. I.M.S., R. H. Miller, M.R.C.S., L.R.C.P., J. Dunlop, M.B., B.Ch., C. R. Patton, M.B., Ch.B., O. Arnott, M.B., B.S.Durh., C. S. G. Mylrea, M.D., C. J. H. Pearson, M.R.C.S., L.R.C.P., J. Y. Ferguson, M.D., C.M., B. W. F. Wood, M.B., Ch.B.Leeds

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Contributors are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Reprints.—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

THEN AND NOW.

Patient: I remember you cured me of the same trouble a dozen years ago; why don't you use the same treatment now?

Doctor: A dozen years ago, he echoed. My dear Sir, the medical profession has made wonderful strides since then, and I could'nt think of such a thing.—"Everyone's Story Magazine" for August.

INTERNATIONAL EXHIBITION OF HYGIENE AT LIMA.

An international exhibition of Hygiene will be held at Lima, Peru, from November 2nd to December 31st of this year. Exhibits will be received of pharmaceutical goods, apparatus, machines, milks, foods and everything connected with the preservation of health, and the Peruvian Government will exonerate all such exhibits from Consular fees. Requests for space and position may be sent until September 17th. Any further particulars needed will be supplied by any Peruvian Consulate in the United Kingdom, or will be forwarded on application to the office of the Medical Congress, Plaza de la Exposicion, Lima.

Dr. H. D. M.—The report appeared in a contemporary, we cannot therefore insert your letter of correction, as the erroneous statement was not published in our columns.

S. W. R. (Bournemouth).—The use of a suitable depilatory is unattended by any risk, or indeed by any inconvenience. We append a formula which can be used for removing hairs from moles or from the skin of the limbs of young women without exerting any noticeable irritating effect on the skin. Some caution, however, is necessary in applying it to more sensitive parts, such as the upper lip, scrotum, etc.:—℞ barium sulphide 5 parts, powdered iris root 5 parts, zinc oxide 10 parts, powdered starch 10 parts. These ingredients are thoroughly mixed and when about to be used are made into a thin paste with a minimum of water and forthwith applied to the hirsute surface. Wash off in two or three minutes when the hairs will have disappeared. The only objection is a powerful odour of sulphuretted hydrogen—in the air, not on the arm.

Pensator.—Experimental inquiry has shown that gall-stones, chiefly composed of cholesterine, are soluble in normal bile.

Double Qualification.—The clause in the bond mentioned is too explicit to leave any doubt as to its intention.

House Surgeon.—Our correspondent is advised to write a private note to the coroner, asking him to reconsider the claim.

F.R.C.S.Edin. (London, S.W.).—The dog is stated to be three times more liable to tuberculosis than the cat, and 500 times more so than the horse, which, though not absolutely immune, is rarely attacked.

THE LEAGUE OF MERCY.

The annual report of the League of Mercy shows that the receipts last year amounted to £21,708, being an increase over the previous year of £1,492. Of this total, £18,000 was given to King Edward's Hospital Fund for London and £2,305 to various county and other hospitals.

Since the formation of the League of Mercy in 1899, upwards of £200,000 has been distributed—£188,000 going to King Edward's Hospital Fund, and £12,066 to extra-Metropolitan hospitals in districts working for the League. The two districts heading the list last year were South Kensington, which collected £1,375, and South Paddington, £1,220. Each year a larger number of hospitals decide to keep their accounts on the uniform system. In this way, alone, an accurate knowledge of the relative economy and efficiency of each participating charity is obtainable.

Dr. P. N. T. (Devon).—The sugar derivative known as hediosite has been shown by Professor Rosenfeld, of Breslau, to be one of the least harmful of all the carbohydrates to diabetic patients. It may be given to the extent of two ounces per diem, or even more.

Appointments.

Burton, A. H. G., M.D.Lond., D.P.H.Camb., Tuberculosis Officer and Assistant Medical Officer of Health for the Metropolitan Borough of Deptford.

Bywater, H. Haward, M.D.Vict., F.R.C.S.Edin., D.Ch.O.Liverp., Assistant Honorary Surgeon to the Liverpool Eye and Ear Infirmary and Assistant Honorary Surgeon to the Eye, Ear, and Throat Department of Wigan Royal Infirmary.

Clark, A. J., M.B.Cantab., M.R.C.P.Lond., Lecturer in Pharmacology to Guy's Hospital

Curtis, Henry, B.S.Lond., F.R.C.S.Eng., Surgeon to the Metropolitan Hospital, Kingsland Road, N.E.

Langran, W., L.R.C.P. and S.Edin., Certifying Surgeon under the Factory and Workshop Acts for the Axminster District of the county of Devon.

Locke, [illegible]. Lindsay, M.B., Ch.B.Edin., Senior Medical Radiographer to Guy's Hospital.

Macrae, Farquhar, M.B., C.M.Aberd., Tuberculosis Officer for the County of Aberdeen.

Metcalfe, James, M.D.Brux., L.R.C.P. and S.Edin., Medical Officer in charge of the X-Ray Department of the German Hospital, London.

Mitchiner, P. H., M.B., B.S.Lond., House Surgeon at St. Thomas's Hospital.

Parkinson, John, M.D., B.S.Lond., M.R.C.P.Lond., Special Assistant to the Heart Department of the London Hospital.

Pickard, Ellen Mary, M.D., B.S.Lond., Assistant to the Clinical Pathologist at the Royal Free Hospital.

Richards, Maude M., M.B., B.S.Lond., Assistant to the Clinical Pathologist at the Royal Free Hospital.

Vacancies.

Herts County Asylum, Hill End, St. Albans.—Second Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Bristol Royal Infirmary.—House Physician. Salary £100 per annum, with apartments, board, and laundry. Applications to W. E. Budgett, Secretary and House Governor.

Bristol Royal Infirmary.—House Surgeon. Salary £100 per annum, with apartments, board, and laundry. Applications to W. E. Budgett, Secretary and House Governor.

Bradford Royal Infirmary.—House Physician. Salary £100 per annum, with board, residence, and washing. Applications to J. J. Barron, Secretary-Superintendent.

Monmouthshire Asylum, Abergavenny.—Second Assistant Medical Officer. Salary £225 per annum, with board, furnished apartments, washing, and attendance. Applications to the Medical Superintendent.

Oxford County Asylum, Littlemore, near Oxford.—Assistant Medical Officer. Salary £150 per annum, with apartments, board, and washing. Applications to the Medical Superintendent.

Devon County Asylum.—Junior Assistant Medical Officer. Salary £200 per annum, with furnished quarters, board, and laundry. Applications to the Medical Superintendent of the Asylum, Exminster.

Manchester Royal Infirmary.—House Surgeon. Salary £100 per annum, with board and residence. Applications to Walter G. Carnt, General Superintendent and Secretary.

Leeds Public Dispensary.—Junior Resident Medical Officer. Salary £100 per annum, with board and residence. Applications to the Secretary of the Faculty, Public Dispensary, North Street, Leeds.

Royal South Hants and Southampton Hospital.—House Surgeon. Salary £100 per annum, with rooms, board, and washing. Applications to T. A. Fisher Hall, Secretary.

Wolverhampton and Staffordshire General Hospital.—House Surgeon. Salary £125 per annum, with board, furnished rooms, and laundry. Applications to J. Stephen Neil, House Governor and Secretary, Wolverhampton.

Births.

Bahr.—On August 2nd, at 50 Iverna Gardens, Kensington, W to Dr. and Mrs. P. H. Bahr—a daughter.

Taylor.—On August 4th, at La Jaspellerie, Sark, Channel Islands, the wife of Ashby Taylor, Medical Officer of Sark, of a son.

Unwin.—On August 4th, at Penn Hill, Yeovil, the wife of Harold R. Unwin, F.R.C.S.Eng., of a son.

Marriages.

Maunsell—Peile.—On August 9th, at St. Peter's, Cranley Gardens, Captain Eustace Ball Maunsell, 35th Scinde Horse, elder son of Colonel C. A. Maunsell, R.A.M.C., to Mary Braithwaite, eldest daughter of the late Charles Peile and Mrs. Peile, of 14 Queen's Gate Gardens.

Deaths.

Fox.—On August 5th, at Holly Bank, New Brighton, Edward Austin Fox, M.D.Durh., J.P., L.R.C.P. and S.Edin., aged 68.

Grey-Edwards.—On August 5th, at Bank Place, Bangor, Henry Grey-Edwards, B.A., M.D.Dub., aged 57.

Middlemiss.—On August 4th, at his residence, Wear Court, Darlington, George Middlemiss, M.D., V.D., aged 68 years.

Pell-Ilderton.—On July 26th, at Saxonholme, Higher Openshaw, Manchester, Harry Pell-Ilderton, L.R.C.P. and S.Edin., aged 61.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, AUGUST 20, 1913. No. 8.

NOTES AND COMMENTS.

The Government Moves.

THE announcement that a Royal Commission has been appointed by the Government for the institution of an inquiry into venereal diseases will be hailed with profound satisfaction, not only by the medical profession, but also by all who have the interests of the public health at heart. The exact terms and scope of the inquiry to be set up are still under consideration, but, presumably, the members of the Commission will include some of the signatories of the important medical manifesto to which we referred in our last issue. This preliminary investigation by the Government cannot fail to be the beginning of a new era in the treatment of syphilis and allied diseases, and now that public opinion has been stirred to some extent by the publication of the appeal in the columns of two important daily newspapers, there is every hope that a great national campaign against what Lord Morley has characterised as "this hideous scourge" will now be commenced. Whether or not a system of confidential notification of venereal diseases be advisable in this country is debatable, but that these affections can be controlled in a community is exemplified by the experiences in India, Egypt and Malta of Major H. C. French, R.A.M.C., whose thoughtful paper read at the International Congress of Medicine contained many valuable suggestions. At any rate, no time should be lost in educating and protecting the public in regard to a disease which is just as much worthy of organised effort as tuberculosis. In yielding to the urgent demands of the medical profession in a matter affecting the public health so greatly, the Government may be heartily congratulated for its action which should command the approval of every section of the community.

Amateur Doctoring.

SOMETHING of a sensation, at least from the point of view of the man in the street, was afforded by Dr. A. L. Soresi, of New York, in his paper on "Preventive Medicine Attainable Only by Compulsory General Medical Education," read before the Section of Hygiene and Preventive Medicine on the final day of the Congress last week. He pleaded that people should "be taught to study medical questions just as they are all taught to read and write." This statement can hardly be taken seriously, for it is quite contrary to the generally accepted idea among the profession that the general public should be encouraged to dabble in things medical. More harm than good invariably results from amateur doctoring—which, after all, is only a species of quackery—for it is manifestly absurd to suppose that an untrained person possessed of average intelligence can understand those therapeutic intricacies and appreciate all the knotty points of diagnosis that frequently baffle the skill of a medical man who has studied these problems for many years. It is true that the public are generally very ignorant of the simplest anatomical and physiological facts and make the most ludicrous mistakes when attempting to locate their symptoms. There can be no harm in educating the young in classes in elementary physiological facts; on the contrary, such knowledge is likely to be of some practical use. Similarly, instruction, judiciously imparted, in first aid and home nursing is of real public utility, and it cannot be said to make for quackery directly. It would serve no good purpose, however, to render such studies compulsory upon all. Let the layman learn the position of his liver, by all means, and also its functions, but do not arm him with a sheaf of prescriptions for "biliousness."

The "Stock Mixture."

THE principle of time-saving has crept into medical practice in many directions, and this is illustrated best, perhaps, in the art of prescribing. Quite early in his medical career the student acquires the habit of writing "Mist. F.A.," to signify the "Mistura Ferri Apериens" of his hospital pharmacopœia, and he would probably be voted something of a nuisance were he to write out an elaborate prescription for every out-patient with all sorts of odd quantities minutely specified. The work of dispensing for many hundreds of patients daily at the large hospitals is truly Herculean, and, in order to save unnecessary labour, it is absolutely necessary that "stock mixtures" should be prepared of proved efficacy in certain types of disease. Little would be gained, in the vast majority of cases, if the prescription were specially written, for it is quite a simple matter to add an extra ingredient or to direct the omission of another, as occasion demands. In a large general practice the same question arises, and the "stock mixture"—*e.g.*, "Mist. Tussis" or "Mist. Stomachica"—is such an old inhabitant of the surgery shelves that to dislodge it from its old place would be exceedingly difficult, and it is doubtful whether its banishment would lead to greater efficiency in treatment. It is reported that the question was brought up at a recent meeting of the Council of the Pharmaceutical Society, and that a resolution deprecating the practice of prescribing in this fashion was carried. If the chemists like to make work for themselves, all well and good; but it is surely within the discretion of the medical practitioner to prescribe as he believes will be in the best interests of his patients, and of this he alone is the best judge. A good "stock mixture," composed of carefully selected drugs, each acting in a known manner, and whose virtue has been proved over and over again, is a totally different thing from a proprietary remedy, the actual composition of which may or may not be known. There are circumstances, of course, in which it would be unwise to order a "stock mixture," but, on the whole, it may be stated, without fear of contradiction, that a medicine so prepared is indispensable to medical practice.

LEADING ARTICLES.

THE TURN OF THE MEDICAL KALEIDOSCOPE.

FEW great discourses that have been given of late by distinguished leaders among the medical profession have provided so much food for reflection as the Address in Surgery before the 17th International Congress of Medicine delivered by Professor Harvey Cushing, of Harvard University, a full abstract of which is published in the present issue of this journal. A greater defence of experimental research has, probably, never been more eloquently made by any medical man speaking before a medical audience. The whole range of preventive medicine in every clime was reviewed by Professor Cushing, who showed at every step the beneficial results that have accrued to mankind as a direct result of experiments upon animals. Such practical advances as the ridding of a malarious district of mosquitoes, the demonstration of the causes of tuberculosis and syphilis, the methods of preventive inoculation—to name only a few recent achievements of medical science—would not have been possible but for the fact that the lower animals have been made the subject of painstaking experimentation for man's sake. The chemical pathologist has allied his skill with the bacteriologist and the entomologist in order to assist in unravelling some knotty point of ætiology or diagnosis. The so-called methods of vivisection are none other than those practised upon human beings, and who will deny that these same methods, whose primary object is the study and cure of disease, have benefited not only man, but also the lower animals themselves? Of the general relations of medicine and surgery much the same idea was expressed by Professor Cushing as Sir Berkeley Moynihan in his Address in Surgery, delivered at Brighton, on "The Gifts of Surgery to Medicine" [*vide* THE MEDICAL PRESS AND CIRCULAR, August 6th, 1913, p. 141], *i.e.*, the "surgicalisation" of many branches of internal medicine within the last few years. Far from separating internal medicine and surgery, Professor Cushing believes that these are actually converging, because the treatment of disease is gradually becoming less empirical. Surgical specialisation is the order of the day, but it might be well if those who confine themselves rigidly to the practice of one branch of surgery could now and then become absorbed in general surgery, to re-emerge with fresh conceptions of disease and its treatment. Another point touched upon in the Congress address is the rapidly-vanishing tendency to disparage the use of instruments of precision in medical and surgical practice. Although the *tactus eruditus* is a priceless gift, both to the physician and to the surgeon, yet no practitioner who wishes to do the best for his patient can afford to dispense with the assistance provided by modern scientific apparatus and other laboratory accessories. A graphic description is given of the contrast seen to-day between the modern methods of investigating a difficult case and the old-fashioned routine of the mere prescription and a medicine bottle! It must not be supposed, however, that the most perfect instrumental *technique* can ever wholly supplant the habit of acquiring clinical knowledge by means of the unaided senses. Though times are moving fast and the kaleidoscope of surgery as well as of medicine is continually shifting, Professor Cushing has aptly reminded us that the present realignments of medical science may be nothing more than fleeting re-arrangements of older methods.

THE SURGERY OF THE FUTURE.

SINCE Carrel showed it to be possible to preserve organs and tissues outside the body, if not indefinitely, at any rate for a long time, to get them to grow and, on restoration to the body, to start a fresh lease of functional existence, the limits of surgery have been hugely widened. Not indeed that it has as yet become possible to exchange old kindeys for new or to acquire a brand new reproductive apparatus in exchange for certain fees and emoluments. No, that we fear is never likely to come to pass, but we are justified in asserting that Carrel's experiments have rendered such things conceivable, which, before, they were not. How do matters stand? Well, he can remove both kidneys, ureters and a portion of the bladder in a dog, resect the arteries and veins, smear them with vaseline, and put them aside to air, all this for some hours, then restore them to their rightful owner and within twenty-four hours or so the animal is running about, secreting and ejecting urine in the most approved fashion, and "lives happy ever after,'' at any rate for two years, as shown by actual observation. This doubtless is brilliant, regarded as a feat of surgery, but from any other point of view it is mere waste of energy. No one wants his kidneys taken out and put back again, as an exhibition of surgical gymnastics. What he wants—if he wants anything—is to substitute another set for those which have gone on strike and unfortunately this is precisely what, for the time being, even Dr. Carrel is unable to accomplish. This is the more disappointing because, as a matter of fact, he can and does exchange the organs aforesaid as between two dogs, and for some days or weeks everything progresses admirably, but—and this "but" is aggravating—in a fortnight or so the transplanted kidneys set up nephritis, to which the animals succumb. In other words, there is something in one's own organs which is distinct from alien organs, however similar in race and age they may be. Doubtless there are beings so similar in build and function that this transfer would prove successful, only, so far, he has not lighted upon the ideal pair. This point is all-important, because until the cause of this incompatibility has been elucidated Carrel's surgical legerdemain must fail to realise what we are all so eagerly looking forward to, viz., the possibility of repairing the human machine as the parts deteriorate, just as we do in an engine. If this difficulty can be overcome, if we can, piece by piece, replace peccant organs and tissues, a quasi-immortality would be within measurable distance. Whatever results in this direction be achieved by further research, however, we are never likely to emulate the state of the umbrella of which, in consequence of repeated replacements, nothing of the original remained. There is a humorous aspect to this question, an element usually conspicuous by its absence in matters appertaining to surgery, but the underlying facts are solidly established and have been verified by numerous competent and potentially hostile critics. For instance, the surgeon need no longer appeal to reluctant relatives or friends to part with scraps of skin for grafting purposes, since Dr. Carrel is in a position to supply unlimited quantities of fœtal skin, guaranteed free from spirochæte and tubercle bacillus, preserved by cold storage, and fit in every respect for the purpose in view. He has bits of aorta and vena cava which can be utilised as substitutes for damaged segments with every assurance of success, in fact there is no tissue which has proved recalcitrant to his surgical tricks. It is only the highly differentiated, alien organ which, for the time being, cannot be induced to "accept service" for more than a limited space of time. The application of "cold storage" to the preservation of tissues and organs recalls Hunter's famous theory that, as freezing entailed no destruction of organs, there was no reason why, on thawing, vitality should not return, a theory which he was anxious to try on himself and would doubtless have done so had not anxious friends prevailed on him to try it first on an animal, an experiment which yielded disappointing results. Possibly, however, the last word on this subject has not yet been said, for we are plainly only on the threshold of a new departure, pregnant with unimaginable consequences.

CURRENT TOPICS.

Protective and Curative Typhoid Vaccination.

The employment of anti-typhoid vaccine for protective, as well as for curative purposes, is receiving a great deal of attention in France at the present time. Although there are rival claimants for the public favour that vaccine employed in the French army and navy and colonial forces, known as Vincent's polyvalent vaccine, is the only one which so far has been enabled to demonstrate its efficacy, no doubt, because its inventor is the chief medical officer of the French Army. This vaccine is a suspension of typhoid bacilli, sterilised by heat, so that it is of the nature of a chemical solution. Curiously enough one of the results of the early attempts at protective vaccination against typhoid fever was to emphasise the fact that the disease is not a morbid entity, that the clinical symptoms and pathological signs of ordinary typhoid may be produced by several distinct species of bacillus, which do not react to the same biological test. Hence the necessity for making the vaccine polyvalent, or as nearly so as may be. Vincent's polyvalent vaccine is a suspension of typhoid bacilli killed by a high temperature and, therefore, perfectly sterile. Its strength is calculated according to the number of contained bacilli, which are counted in the same way as blood corpuscles. For protective purposes a hundred million may be injected under the skin, generally over the insertion of the deltoid, but the vaccine is also employed for curative purposes and then it becomes necessary to proceed very cautiously, not more than six or ten million being administered every five days. Used prophylactically, the results have been most brilliant, indeed, absolutely convincing, so much so that the method is bound to come into general use for the purpose of protecting populations in epidemic periods, and to prevent the infection of nurses, students and others in attendance upon the typhoid sick. There is every reason to believe, moreover, that, employed for therapeutical purposes, the vaccine materially reduces the mortality, but the results, though distinctly encouraging, cannot as yet be regarded as absolutely conclusive.

Noble Simplicity.

There is no doubt we are different from what we were. Whether we are catching up on our ideal or whether our reality is slipping from our grasp is another story. To-day we are all meteorists. Optimism is in the air, and we are trying to solve life's harder questions by analysis. We have seen the tendency at the Medical Congress. Learned men have discussed simple things. They studied sea-bathing and street noises with an enthusiastic modesty that is likely to make good, and they realised the importance of everyday things that an old time physician would have thought beneath his dignity and would never have mentioned seriously, at any rate in plain language. Medicine is getting less of a mystery every day. Abracadabra and hey presto have lost their therapeutic reputation. It is a good thing, both for the profession and the people. But the latter still require education. They will not understand that their body is comprehensible. Hence the success of quacks and their vain verbosity. All the same, the man who knows is coming into his own, and the laity will soon see that a doctor whose words they can understand may be just as efficient as one who suffers from a lingual diarrhœa of the lienteric type.

The Treatment of Rheumatoid Arthritis.

The failure of treatment to ameliorate that distressing infective polyarticular affection known generically, as rheumatoid arthritis, is in all probability due, in great measure, to the fact that the same treatment is applied in all cases. Now each case must be dealt with on its merits, so to speak, tentatively. In some, sufficient and persistent doses of an organic compound of arsenic will work wonders, though falling short of complete cure. Other cases prove strikingly amenable to the cautious but persevering administration of thyroid extract, more particularly what we may call the florid cases, in which the patient displays more or less pronounced obesity. In febrile cases with a tendency to emaciation, the vaccine treatment appears to be indicated, though this department of therapeutics is still in the experimental stage. In this last named category of cases remarkable improvement has sometimes been noted from the intravenous or intramuscular injection of colloid silver. We must, therefore, not regard rheumatoid arthritis as an incurable disease though, on the other hand, it is admittedly at times a very refractory affection. It is hardly necessary to add that the success of any treatment is conditional on the removal of any manifest source of chronic intoxication, such as carious teeth, pyorrhœa alveolaris, gastro-intestinal fermentation, chronic appendicitis, etc. To arrest the further course of the disease and to bring about the subsidence of lesions which have not gone beyond the inflammatory stage is as much as we can hope to achieve, but this constitutes a remarkable achievement with which most patients will be content.

Subcutaneous Oxygen.

It is only during the last year or two that a tendency has become manifest to afford quasi-asphyxiated patients the full measure of benefit to be obtained from the inhalation of oxygen. Previously it was regarded, or at any rate treated, so to speak, as of the nature of a viaticum, a something to be administered as a matter of routine as soon as it became obvious that the angel of death was hovering over the patient. Even so its effects, if fugitive, were none the less remarkable, though many a humane physician must have inwardly doubted the wisdom of thus rashly calling back to temporary consciousness persons who were in any case lost to the world. Employed early, oxygen may well tide over the crisis by averting immediate oxygen starvation. Administered in the usual way with a funnel-shaped mask, or passed directly into the patient's mouth *via* a tube glass, none can tell how much is going into the lungs, so that the practitioner is working somewhat in the dark. Then, too, this method is extremely wasteful, because much of the oxygen escapes into the air. Much simpler and more practical is the recently introduced plan of injecting the gas under the skin of the abdominal wall. All that is necessary is to connect the tube of the oxygen bag with a hypodermic needle and squeeze the bag until a sufficient amount has been injected. Or, if greater accuracy be desired, the gas can be pumped in by utilising an ordinary rubber bulb syringe of the Higgenson type, the capacity of which is easily estimated. From 200 to 400 c.c. may be injected at a time, and as its absorption is very gradual the effect is maintained, which can never be the case when inhalation is practised.

"Here's a Skull, Now."

SOME bits of cranium and a mandible. That is the Piltdown skull. And it is causing quite a lot of trouble. When it was dug up in Sussex a few months ago, it was hailed with unmixed joy by the comparative anatomists. Now it is literally a bone of contention. It is agreed that it is an old skull belonging either to the Late Pliocene or to the Early Pleistocene period. It is also agreed that the shape of the jaw makes it impossible for the original owner to have talked. The argument is about the size of the brain. Dr. Keith and Dr. Smith Woodward have each "reconstructed" the skull, and their results differ. Dr. Keith makes the brain as great as that of a modern man, and decides that it belonged to a human being whom he calls *Homo Piltdownensis*. Dr. Woodward has found the brain considerably smaller, and has classed it as that of a new *genus*, *Eoanthropus Dawsonii*. The Germans approve of neither reconstruction. So we have all the makings of quite a pretty argument. As befits so solemn a subject the discussion is being carried on at considerable length, and with commendable restraint. Of course, one of the greatest benefits that these discoveries confer on us is that they give us something new to talk about. So let us take sides and be savage while there is yet time, for to-morrow someone will dig up a new old skull and the Piltdown specimen will sink into oblivion as deep as the gravel whence he came.

The Treatment of Epithelioma.

THE fact that in its early stages epithelioma is a local affection has furnished the surgeon with inspiration and hopefulness in his tedious crusade against malignant disease generally. There are many methods of dealing with epithelioma surgically, among which that of free excision is probably the best. Unfortunately, it is not possible to use the knife in all situations and in the later stages of the disease when the deeper tissues are involved. Ravogli, an American surgeon, has introduced a new preparation for the destruction of the morbid growths. He uses a mixture of formalin, lysol and perchloride of iron: formalin as a parasiticide and disintegrator of the epithelial infiltrating cells, lysol as a solvent of the hypertrophic connective tissue elements, and perchloride as a styptic. The formula for the mixture, to be freshly prepared, is formaldehyde 2 parts, lysol 2 parts, ferric perchloride 1 part, applied with cotton swab. The surface of the epithelioma is first washed with green soap, treated with 5 per cent. solution of cocaine, curetted; and treated with the application for five minutes. Good results are claimed by the author for this mixture, which is cheap and effective.

A New Remedy for Alopecia Areata.

THE physiological correlation between function and growth and the interdependence of the well-being of the various organs upon each, possess a therapeutic value, the knowledge of which is often usefully applied. But occasionally, when the functional integrity of an organ is for some reason disturbed, surprising effects are produced, the cause of which is apt to be mistaken or overlooked. In this connection a somewhat remarkable instance was given by Dr. Whitfield at a meeting of the Dermatological Section of the International Medical Congress. In the course of a discussion upon the subject of alopecia areata, he stated that he had often found the disease to depend upon an error of refraction. As soon as the necessary correction with lenses had been made, the symptoms ceased and the hair began to grow again. For this and other reasons he had come to regard alopecia areata rather as a symptom than a disease. It is, of course, well known that to errors of refraction have been assigned a host of diverse diseases, from epilepsy downwards. Some years ago it was even claimed that a notorious murderer, who paid the usual penalty for his crime, owed his criminal degradation to uncorrected hypermetropic astigmatism. Dr. Whitfield's observations, nevertheless, are interesting as showing that an uncorrected error of refraction may have a far-reaching effect, even in the least expected direction. The puzzle, however, is how to explain the fact that an error of refraction uncorrected may affect the nutrition of the scalp as to arrest the growth of the hair.

The Colloids.

Though it is now many years since Bredig first called attention to the nature of colloid substances, it is only during the last few years that they have shown any tendency to emerge from obscurity and to take rank in therapeutics. Physically the colloid state is as curious as it is ill-understood. A colloid metal is really a metal which has been converted into an ultra-microscopic powder, suspended in a liquid of some sort. These particles are so minute as to be with difficulty perceived even by the aid of the most powerful instruments, all the more so as they are animated by very active Brownian movement. Now the physiological activity of a given metal depends upon its surface area, consequently a fluid containing innumerable billions of these particles, each with its electric charge, produces effects vastly greater than the same quantity of the metal in the form of a chemical compound. The animal organism is largely made up of colloid substances endowed with their own specific properties, and life is associated with the interaction of these colloids. Toxic bodies converted into colloids exert marked physiological effects, while the toxic action is reduced well nigh to vanishing point, because the actual quantity of the body present is comparatively small. There is probably a great future for this class of bodies, especially as they promise to render service in many morbid states toward which so far we have been without arms, septicæmia and other grave constitutional infections to wit.

Mash that Mosquito!

The United States, with its policy of *sanitas sanitatum, omnia sanitas*, has made the Isthmian Canal zone into something comparable to a health resort. The anti-anopheline campaign, based on drainage, oil and muslin, has worked wonders. Now there is a new way. The apparatus are a nigger, a "slapper" made of a six inch square of wire gauze on a stick, and a wide test-tube with a piece of cotton-wool soaked in chloroform in it. The "slapper" is used when the mosquito rests on the screen. For other situations this is the *modus operandi*. (*a*) "The collector having spied an anopheline, uncorks his vial and gently but rapidly places it over the insect. In a moment the chloroform fumes overcome the insect, and it drops into the tube." It sounds delightfully easy, but seems to us rather a waste of good chloroform. Besides, the sturdy mosquito might recover from the anæsthesia and escape. On the whole, we prefer the good old English way of taking the insect firmly by the back of the neck, placing its head accurately over the centre of a smooth brick, and hitting it smartly with a heavy hammer. This will be found to involve no expense beyond the occasional renewal of the brick, and to be quite as efficacious as the method described above.

The Growth of Medical Knowledge.

If any indication were wanted of the vast strides accomplished in medical knowledge during recent years, it is surely supplied by the enormous variety and number of the communications read and discussed at the seventeenth meeting of the International Medical Congress. These quatrennial international crystallisations of the advancement of the science and art of medicine are good for nations as well as for the individual—they stimulate enterprise in original research; they infuse a commonality of feeling among all those taking part in them, tending to make the matter of racial distinction one of insignificance; they become the means of valuable friendships being formed by the interchange of amenities, which otherwise would have been impossible. Contrasting the results of the Congress just held with that of the seventh Congress held in London in 1881, the advancement in all respects has been phenomenal. The increase in the number of sections alone is significant of the progress made. Moreover, the transactions of the 1881 Congress are contained in four volumes, while it has been stated that forty volumes will be required to contain the full report of the proceedings of the Congress just held. It may be, however, that this is an exaggeration, despite the official source from which it came. Nevertheless it prompts the reflection that if, as has been shown, the advance in medical knowledge in thirty years has extended to such dimensions, who can foretell the result of the next International Medical Congress which will be held in London? If in thirty years' time much medical knowledge has now become commonplace which in 1881 was unknown, how much are we now out of date, in comparison with that which the next thirty years will reveal? This is a conundrum which only those who succeed us will be able to determine. It will scarcely lie within the sphere of those to whom it has been possible to attend each of the two last congresses in London to supply the solution.

PERSONAL.

Mr. T. Milnes Bride, M.D.Vict., has been appointed Honorary Ophthalmic Surgeon to the Northern Hospital for Incurables, Manchester.

Dr. John Benjamin Hellier, M.D.Lond., has been appointed an Examiner in Midwifery and Diseases of Women to the Royal College of Physicians of Lon[illegible]

Mr. John Crew, M.R.C.S., L.S.A., of Higham Ferrers, Northants, formerly president of the South Midland Branch of the British Medical Association, who died on June 16th, aged 76, left estate of the gross value of £47,647, of which £44,017 is net personalty.

Sir Patrick Manson, K.C.M.G., F.R.S., M.D., was the recipient of a handsome portrait medallion in gold at the meeting of the Section of Tropical Medicine and Hygiene on August 11th, as a tribute of respect and esteem from all his fellow-workers and admirers in the domain of tropical medicine in France.

The Council of the Royal Institute of Public Health have appointed Professor Edward William Hope, Professor of Public Health in the University of Liverpool, Medical Officer of Health for the City and Port of Liverpool, and President of the Society of Medical Officers of Health, to be honorary secretary to the Institute.

CLINICAL LECTURE
ON
ENLARGEMENTS OF THE SPLEEN IN CHILDREN. (*a*)

By HUGH THURSFIELD, M.D.Oxon., F.R.C.P.Lond.,

Physician to the Metropolitan Hospital, Assistant Physician to the Hospital for Sick Children, Great Ormond Street, London, W.C.

The subject of my lecture this afternoon is that of enlargements of the spleen in children. Some years ago, when I was learning physiology, physiologists were much divided as to the functions of the spleen; and I believe that that is still the case. I looked up one or two of the more modern books, and on this subject they appear to be as much in the dark as ever. So one does not approach the pathology with any clear interpretation of the facts of physiology. But it seems clear from the clinical evidence, that whatever else the functions of the spleen may be, the organ is intimately concerned with the alterations in metabolism which occur in the case of infections. And it is probably fair to assume, clinically, that in the great majority of enlargements of this organ we have to do with infective processes. Some of the enlargements are clearly due to infection, others not so clearly, but with considerable probability.

I propose to make a few remarks about the anatomical diagnosis of enlargements of the spleen, and then to deal with the clinical classification. I need not remind you that the spleen occupies the left side of the body, under the cover of the ribs; but it may be worth while to recall that normally in a child the spleen occupies an area immediately beneath the 9th, 10th and 11th ribs, in the mid-axillary line, that the splenic dulness in the normal child can never be demonstrated higher than the 9th rib in the mid-axillary line, and that it lies in such a position that the 10th rib forms a midline through the long axis of the spleen. In the enlargements of this organ, usually there is not very much difficulty in making up one's mind that one is dealing with an enlargement of the spleen. The reason is that the organs generally are so easily felt in a child through the comparatively non-muscular abdominal wall, that you [illegible] that you can [illegible] the kidney by the fact of the different relation of the descending colon to the tumour; that this colon will lie inside in relation to an enlarged spleen, and outside or over an enlarged kidney. And that, no doubt, is, broadly speaking, true. I saw a case at a *post-mortem* examination the other day in which a tumour originating in the kidney had become attached to the posterior surface of the descending colon, and had carried that in front of it, so that the colon lay right across the front of the tumour, offering a definite band of resonance as against the dulness of the tumour. But it is not always so; I have seen kidney tumours growing with the colon entirely to the inner side. The point which I have found most useful is to remember that a kidney tumour rarely reaches the upper border of the 9th rib in the mid-axillary line; and if there is a definite dulness above that, it is probable one is dealing with an enlargement of the spleen. It is possible to conceive that the kidney tumour may push the spleen up, and so increase the dulness, but I do not think that is at all common. The second point in diagnosis is that a kidney tumour invariably goes much further back in the loin, and your fingers placed at the outer border of the quadratus lumborum muscle in the back can communicate with the hand placed in front of the tumour. Another difficulty is sometimes caused by scybala due to chronic constipation, as, for instance, in a case of Hirschsprung's disease. Two or three years ago I, in combination with many other people, diagnosed enlargement of the spleen for which we were unable to account, in a boy of about five years of age, who died suddenly, and was found to be the subject of congenital dilatation of the colon, with enormous masses of scybalous fæces in the descending colon, which we had mistaken for enlargement of spleen.

Particularly in adults, of course, the growths in the descending colon have to be taken into consideration. But in children these are very rare, and I have never seen in a child a tumour of the descending colon which could have been mistaken for enlargement of spleen; but twice I have made the mistake—and have seen it made by other people—of diagnosing an enlarged spleen as a case of tuberculous peritonitis, and *vice versa*. I remember one boy who had leukæmia, with a spleen nearly down to his iliac crest, and was seen by three people, of whom I was one, who with one consent diagnosed tuberculous peritonitis.

The clinical enlargements one may divide into the acute and the chronic infections. The acute infections in which the spleen is enlarged to any degree are not many, the chief being typhoid fever; but the number of children so affected is small. In most cases of typhoid fever in children you can feel the spleen one or two inches below the margin of the ribs, but in two per cent. or three per cent. of cases the spleen forms a much larger tumour, reaching to the level of the umbilicus, and well out towards the middle line. There does not seem to be any difference in prognosis in these cases which have such extra large spleens, nor do I know why the spleen should be so much larger in some cases than in others. In the only case of typhoid fever in a child in whom I have seen the spleen after death, there was great enlargement of it, but there was nothing to distinguish it from the ordinary typhoid spleen. Enlargements of the spleen in typhoid fever are, in my experience, always painless, and are thus opposed to enlargements associated with septicæmia and pyæmia. In this condition there may be a very big spleen, so that when you are called to the child the spleen may be down to the umbilicus, or even lower. Other infective fevers may result in the spleen being just below the ribs. It may be enlarged in even such mild diseases as German measles, or varicella, but one disease in which I have found no enlargement of the organ is rheumatic fever. Should you find it enlarged in a rheumatic condition I think you should suspect

---

(*a*) Delivered at the Polyclinic, London, March 3rd. 1913.

infective endocarditis, with infarcts in the spleen, possibly even splenic suppuration.

The chronic infections of the spleen are not a small class, and I find it difficult to decide on any grouping for them. At first I thought of classifying them as infective and non-infective, but that proved insufficient; then that I would make a class of enormous enlargements and comparatively slight enlargements; but here again there were cross-currents. Finally, I have taken one group to include the diseases called by the names leukæmia and pseudo-leukæmia, and the second a more or less mechanical group. And I have been driven to make a miscellaneous group, in which one has reason to suspect various causes are at work.

The leukæmic group includes both myelocytic leukæmia, and lymphocytic leukæmia, and that form known on the Continent as pseudo-leukæmia, but which in this country we call Hodgkin's disease. It also includes that very remarkable disease described twenty years ago by v. Jaksch under the name pseudo-leukæmia infantum. It is a cumbrous name, but the others which have been proposed for it express either too much or too little. It has been called the splenic anæmia of infants, but it is a misfortune to christen anything splenic anæmia which has characteristics so widely divorced from the splenic anæmia of adults. The name splenomegaly of infants does not tell you enough about it.

In this group the spleen is very large indeed; though in the leukæmias of the lymphocytic form, or what is better called acute leukæmia, the spleen may occasionally not be enlarged at all. But in more than half the cases of lymphocytic leukæmia which I investigated last year the spleen was considerably enlarged. The associated symptoms are purpuric hæmorrhages, bleeding from the gums or from the other mucous membranes, the rapid onset of pallor, and usually considerable fever. The prognosis is rapidly bad; the majority of these cases do not live three months. Myelocytic leukæmia is very much rarer as a disease in children; I have seen four such cases under twelve years of age, and I was only able to find eight others in the literature to which any attention can be paid, because you cannot consider that the differentiation of leukæmias was established until about 15 years ago. We can say that these enlargements are infective processes, but not infections by ordinary bacteria. For some time it was supposed that lymphocytic leukæmia might be a streptococcal infection of the bone marrow, a view supported by evidence which was forthcoming both during life and after death. But the difficulty felt was that if lymphocytic leukæmia was a bacterial infection, so was myelocytic leukæmia, and in the latter no bacterial infection has been demonstrated. Various writers have claimed to demonstrate protozoa intracellularly in these diseases. But none of those have won acceptance from those who are investigating the cause of this disease.

Pseudo-leukæmia infantum is not, so far as I know, seen in children of the well-to-do classes; it seems to be confined to the poorer members of the hospital class. Some of my colleagues believe it is more common in the Hebrew race, but I do not agree with that. You can recognise the subjects of the disease as soon as they enter the room. They have a transparent pallor, which is partly due to œdema of the subcutaneous tissue; it looks much like the œdema in an early stage of Bright's disease. The moment you put your hand on the abdomen you can feel the splenic tumour; it is always enlarged on the first visit to the level of the iliac crest; and generally reaches forward to the middle line, or even beyond it. These cases have, clinically, the biggest enlargement which one meets with in an infant. They were described long before v. Jaksch' time by the late Dr. Dickinson, who attributed the enlargement to lardaceous disease, on what grounds I do not know, for the paper in which he described this condition, which was an excellent clinical description, ending up with an account of the *post-mortem*, gave no evidence that the spleen was lardaceous. The blood changes are certainly different from anything you see in lardaceous disease. And if the child survives —and 60 per cent. of them do—the spleen returns absolutely to its normal size, so that three or four years later you cannot palpate the spleen at all.

Anæmia pseudo-leukæmica is rare, so is lymphadenoma, and that again, in my experience, is not bacterial in origin. Protozoa have been associated with it, but that view has not found acceptance. There is a reversion to the former view which ascribed it to a modification of a tuberculous infection. You may have tuberculous disease superadded to lymphadenoma, but there is a disease—lymphadenoma, Hodgkin's disease, or whatever you like to call it—distinct from tuberculous disease. The characteristics of the enlargement of the spleen you all know under the name of the "hardbake." It is an absolutely solid spleen, though rarely as large as the leukæmic spleen, and studded throughout with more or less transparent nodules of various sizes, of pearly whiteness, sometimes yellowish. Those are set in a deep purple background of the splenic pulp.

Are there any other diseases, not so fatal as this, which can be confused with this clinically? Yes, there are. First, there is syphilis. Two years ago, writing on the subject of congenital syphilis, I expressed the opinion that the spleen was enlarged in two different ways, or rather at two different times in congenital syphilis. No doubt it undergoes an enlargement during the acute stage of the disease, at which time the rashes and epiphysitis appear. During that time I believe the spleen can always be felt; sometimes it is a couple of inches below the iliac crest. After the age of three months, whatever the severity of the disease, I believe the spleen is not as a rule palpable. The second kind of splenic enlargement occurs in connection with the later manifestations of congenital syphilis, at 15 or 16 years of age, in which the spleen is very large indeed; sometimes it is gummatous, with definite caseating gummata in the organ; sometimes it is an amyloid spleen. There is a third group, recognisable by the aid of Wassermann's test. I have seen, in the last two years, four or five cases of children who, without any other sign of syphilis, have developed at the age of seven or eight, a very large spleen. They have not been ill, the enlargement has been found in the course of the ordinary examination; and in two of the cases there has been enlargement of various lymphatic glands. There were two boys recently in St. Bartholomew's Hospital, one of them æt. 6, who was quite well except that during the last six or eight weeks he had developed enlarged glands in the neck and the axilla, one being as large as an orange in the epitrochlear space. He was found to have a spleen extending halfway to the midline, halfway to the iliac crest, and hard. He was not leukæmic, and his blood was normal, neither had he lymphadenoma. Could he possibly be a case of tubercle? Every now and then one comes across a case of glandular tuberculosis in which, without other symptoms, the lymphatic glands in various parts of the body are enlarged, and there is considerable enlargement of spleen. I thought this child had tuberculous enlargement of the spleen. However, he gave a positive Wassermann. We excised the epitrochlear gland, and the microscopical appearances were absolutely characteristic of syphilis, *i.e.*, an enormous accumulation of plasma cells throughout the gland, and the absence of the histological appearances of either tubercle or lymphadenoma. The second boy, who came in a few weeks, showed the same symptoms except that the only enlarged glands were those in the axilla, and there was a rapid clearing up under mercurial inunctions. Looking back, I can recall other cases of the same clinical type, but some of them were tuberculous. If you regard an enlarged spleen as one which is palpable one inch below the costal margin, the enlargements due to tubercle are probably at least half as numerous again as all the rest together. It is seldom that tubercle causes any great enlargement of the spleen; but if it does it is due to caseation, and this causes it to resemble the "hard-bake spleen" of lymphadenoma. The differences to the naked eye are characteristic, because the tuberculous spleen has a lot of perisplenitis, the nodules are less transparent, and the nodules can often be felt during life and are usually painful. So if you have a child with chronic enlargement of spleen of such size as to occupy half the left side of the abdomen, or more, you can exclude leukæmia by looking at the blood, and you can exclude v. Jaksch' anæmia by the fact of the age, for that occurs below 2½ years of age; the leukæmias and lymphadenomas are not seen below that age. When you have excluded leukæmia, you are left to choose between lymphadenoma, tubercle and syphilis. If it is the first of these there will be no alteration in the blood, but there may be a collection of glands which are hard and firm, but which are more often discrete, soft, and quite painless. And, except for pressure of glands behind the sternum, lymphadenoma usually shows no other symptoms. But sometimes we see in these subjects febrile attacks. There is such a case at the Children's Hospital now. During the attack the temperature rises to, perhaps, 103°, and after remaining like that for a week or ten days, it slowly comes down again. There is a week's interval and then it rises again. In the case of syphilis, the histological structure of the gland will help you, and so will the Wassermann test. In the case of tubercle, the only help you will get will be from examination of the gland removed. If that is tuberculous, the presumption is that the spleen also is tuberculous. It is not impossible for these cases with large tuberculous spleens to recover completely. In France they have taken to removing such spleens, and some French surgeons have claimed it as the proper mode of treating these tuberculous spleens. Certainly some of their results are very good indeed.

With regard to rickets, rickets, *per se*, is not a cause of enlargement of the spleen. If in a child suffering from rickets you find obvious enlargement of the spleen, you must look for some other cause. One reason the spleen is more palpable in rickety than in normal children is the confined space of the thorax due to the pigeon-breast or to the sinking-in of Harrison's sulcus, which leads to a splaying-out of the lower ribs, so that the arch of the diaphragm on either side is flattened out, and liver and spleen lie lower in the abdomen. Then there are the group of enlarged spleens associated with disease of the liver. Banti has described a condition in which there is a very chronic disease lasting five to twenty-five years, associated with enlargement of the spleen and eventually with cirrhosis of the liver. He described three stages: anæmia, cirrhosis of the liver, ascites; and I think he has demonstrated that in the particular type of disease which he has tried to distinguish, removal of the spleen at an early stage puts an end to the process. But such cases are extraordinarily difficult to differentiate from cases of enlargement of the spleen due to mechanical causes. When an adult has ordinary portal cirrhosis, in a large number of cases the spleen is definitely enlarged, and forms a large abdominal tumour. I know no means of differentiating such cases from Banti's disease; but if in such cases you attempt removal of the spleen, you merely hasten the patient's end.

These cases of liver disease with enlargement of the spleen include many which we do not understand. Recently much has been written about acholuric family jaundice. That term means that the patient appears jaundiced, but passes no bile pigment in his urine, and never has clay-coloured stools. Often it occurs in more than one member of the family, and is usually congenital. The spleen has been found to be enlarged in about 80 per cent. of the cases recorded. In a boy of nine years under my care who was suffering from this disease, the spleen was removed by my colleague, Mr. Tyrell Gray, and at the operation the spleen weighed 49 ozs. The meaning of the splenic enlargement in acholuric jaundice is quite obscure. Some have thought it is enlarged because of the active destruction of red blood corpuscles, referring to the spleen in the physiologist's old phrase as "the grave-yard of the red corpuscles." That does not seem to me to be an adequate explanation. In pernicious anæmia, for example, where there is a greater destruction of red corpuscles there is seldom such a degree of splenic enlargement.

There is another disease, polycythæmia with splenomegaly, which also is very curious. Apparently the spleen enlarges primarily, and secondarily to that there is an enormous increase in the number of red corpuscles circulating in the peripheral blood. Up to the present, no child has been described as suffering from that disease, though it is known to be a congenital disorder; the adults suffering from it always telling you they have had the disease all their lives. It cannot be long before cases in children are put on record.

Lastly, there are the splenic tumours. With the exception of gummata and hydatids a tumour of the spleen is a rarity, and in children practically unknown. I have never seen a secondary malignant growth in the spleen of a child. Primary malignant growths of the spleen of a child have been described, but are very rare. Then there is the entirely secondary condition which can never be mistaken by anybody who has once seen it, and that is the advanced stage of lardaceous disease. There is a curious satiny appearance of the skin associated with nephritis, and an enormously hard liver and spleen, upon which you can make no impression, even by heavy pressure. It is quite painless, and is associated with either chronic tuberculosis or a chronic suppurative lesion.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by A. F. Tredgold, L.R.C.P. Lond., M.R.C.S.Eng., Consulting Physician to the National Association for the Feeble-Minded, etc., etc. Subject: "Acquired Mental Defect."*

Dr. Agnes McLaren, one of the pioneers of the medical education of women, half-sister of Lord Aberconway, left £4,184.

APEX-TREATMENT
FOR
PULMONARY CONSUMPTION.

By WILLIAM EWART, M.D.CANTAB., F.R.C.P.,

Consulting Physician to St. George's Hospital and to the Belgrave Hospital for Children; formerly Assistant Physician and Pathologist to the Hospital for Consumption, Brompton.

(Continued from p. 169.)

VI.

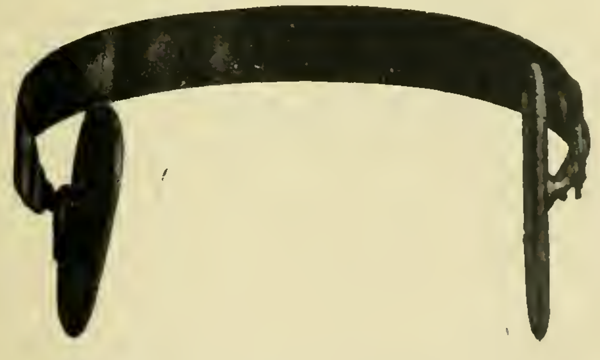
DIFFERENTIAL APEX-TREATMENT AND UNILATERAL BREATHING. CARSON'S METHOD.

Curative Pneumothorax, the great artificial mechanical cure which was to mend some of the late failures of our bacillo-therapy, was sketched in 1882 by Forlanini, (*a*) from nature's spontaneous cure, a few months after the discovery of the bacillus by Baumgarten and by Koch; but it was not carried out by him until 1892, soon after the initial disasters of tuberculin. Both were heroic and fearful experiments; and yet they have been justified by their eventual adoption in our current practice. We are now endeavouring to reason out the means of obviating the necessity for all heroic remedies, including Macewen's pneumectomy and Wilms's retro-thoracic costal mobilisation, besides other forms of mechanical operative treatment, by a simple clinical enquiry, free from serious experimental dangers, into the relative curative merits of apex-inflation and of apex-deflation, of apical rest and of apical exercise, or in mechanical terms, of localised apex-compression, and of unilateral apex-expansion. The "chest-clip," which is merely a convenient appliance in the service of that enquiry, was originally thought out, upwards of three years ago, as an instalment of "differential" apex-treatment, to give to the stricken apex the rest which I then believed, and which is still generally assumed, to be its due; whilst securing for the patient his main curative asset, of which he continues to be partly deprived by over-resting his healthy pulmonary and cardiac functions.

It is striking that curative pneumothorax should have been "invented," and should have been prophesied as "the cure for the disease deemed incurable," before ever it was copied from nature. I must, however, leave that point open for further literary investigation, not having obtained a complete perusal of the writings of James Carson, of Liverpool. It is none the less certain, although this had been forgotten, that *Carson's method* is in the fullest sense his own, and that it was evolved in 1821 from a patient experimental research into the physiology of pulmonary elasticity (*b*). It was first carried out in 1885 by Wm. Cayley, of the Middlesex Hospital, (*c*) at the hands of the late Mr. Hulke, with complete success as regards the arrest of an uncontrollable hæmoptysis from pulmonary aneurysm, though the patient soon after succumbed to his acute miliary tuberculosis. This country took no further part in its elaboration, which was largely contributed by Murphy, of Chicago.

Turning from the historical to the practical argument, we shall find in an analysis of Carson's method its shortest exposition. That treatment is essentially *complete*, as it includes the bacillary cure, although that cure is effected entirely by non-bacillary measures, namely, by purely mechanical forces. Not less complete, too, in that it treats not only the diseased lung, but also the healthy. It is essentially *thorough* in its wholesale dealings. It is essentially *bilateral* and at the same time essentially *unilateral*, for it gives to both sides their separate treatment. It is therefore essentially *differential*, which is the fundamental requirement. Lastly, it is essentially, on both sides, a *local apex-treatment*. Its great faults are that it is heroic in its initial and in its subsequent "one-lung" dangers; and that it is radically unphysiological in its date, *principiis obsta*; as well as in its sacrificing wholesale the pulmonary agent of recovery to the cardiac. It eases the heart of its poison, and strengthens both right and left heart by increased mechanical work—at the cost of abolishing roughly one-third of the respiratory function, and committing life to the hazards of a single lung. We mention its faults merely that they may be avoided. But we must dwell upon its teachings, as a pattern to emulate if we cannot equal it.

Pulmonary Compression and Unilateral Breathing.—No treatment of consumption can be *thorough* which does not aim at that bilateral completeness, at that unilateral differentiation, and at that localising apex-treatment. Likewise no mechanical prevention is as thorough as it might be, if it should neglect the improved means which pneumothorax now suggested. Their mechanism is simple; it rests upon two great factors: (1) Absolute pulmonary compression; and (2) exclusively unilateral breathing.



The Adjustable Chest-clip, showing the Ball-and-socket attachment of the heart-shaped front pad, and the sliding attachment of the spring.

Indirect Thoracic versus Direct Pulmonary Compression.—At the early time we need no heroic measures; neither the solid apex compression nor the absolute physiological apex-rest which are the monopoly of intra-pleural compression; and least of all the "absolute" unilateral breathing. It is enough of rest for the restful apex if we should restrain its extra excursions by steadying the upper ribs. Piorry, (*a*) I only two months ago discovered, was the first to localise, thanks to his ill-honoured accuracy in physical examination, the mechanical treatment to the lesion. He aimed by his "local" flattening thoracic pressures (up to 14 lbs. over a vomica) at an effective pulmonary compression; and he did realise some of our remarkable results of to-day and has recorded some gratifying temporary recuperations. Our own Stuart Tidey

of Montreux (*a*) followed him long after with a method of continuous "general" lung rest and support by strapping down the entire side affected "in the attitude of expiration." He may excuse our attributing his good results to an unintended exercising of the diseased apex, which is thus made to breathe the more unless the clavicular freedom of brachial movement were to be suppressed by a rigid shoulder casing. He has carried out for us with conclusive results our experiment of early curative apex-inflation; imitating on a small scale and in one and the same lung both the pulmonary compression of pneumothorax and its opposite unilateral apex-breathing.

The chest-clip proposes to carry this out, *gradatim and intermittently* by the indirect method of induced unilateral apex-activity, which is our policy of prevention, and which may prove to be also that for earliest cure.

Relative Unilateral Breathing, more correctly perhaps "unilateral over-breathing," is part of our life, the unnoticed perpetual servant of our versatile muscular activities and of our varied recumbencies. And yet it is hardly known by any of us except perhaps by some physiologists, to be one of our "volitional" attributes and not merely an unconscious one. The chest-clip reveals this at once to the least perceptive. We can struggle to breathe "unilaterally" without it; but it is singularly convenient and safe as it is automatic and there is no struggle likely to set up any risk.

Lateral Decubitus.—The familiar question, "Does it matter which side we sleep on?" is not irrelevant. Lateral decubitus is usually discussed in terms of the heart, the stomach, or the liver rather than of the apex. As the circumstances which govern our preference are usually permanent, be it the "wall," the "light," or any other, that preferred decubitus may occupy one-third of our daily life. For the robust this may have little significance. But in predisposed adolescence it cannot be immaterial to invariably restrain for eight consecutive hours the aeration of one and the same apex always. I have not been able to think of any more plausible solution than this for our two ætiological mysteries: in the individual, the unilateral incidence of apex disease, and in the race, the bilateral evenness of that unilateral incidence. It might also fit in, in view of the frequency of a leftward mobility of the heart in association with a sensitive apex beat, with the statement of some statisticians that the right apex is rather more frequently the first to suffer.

For late treatment there can be no rule. But *for prevention* the indication is clear to cultivate the habit of *alternation* in the young. That is also the principle of our diurnal active respiratory apex-culture. The "general" symmetrical respiratory methods are good, some of them appealing more specially to the apices. Our method is "local," definitely apical, but unilateral. It handles each apex separately, and with much more searching effect. Above all, it leaves us in no doubt whether the predisposed apex may not, after all, have remained unexercised. It is not only the safer, but the more thorough method as we may now explain.

Unilateral Breathing in Spinal Culture and in Apex-orthopædics.—Whilst using the chest-clip it soon appeared that it was also available, and that even independently of it unilateral breathing was also available, as an important therapeutic agent for the treatment of the spine, quite apart from any pulmonary disease. I am treating on these lines with most encouraging results a patient with extreme functional cervico-dorsal scoliosis, who had originally come under my treatment six years ago for his resulting paraplegia, from which he gradually and completely recovered under a special method of spinal extension. His present course of treatment, by unilateral breathing, has for its object to lessen the remaining curvature and vertebral rotation. The direct evidence which I have thus obtained of the mobilising and curative effect of unilateral breathing upon the distorted spine has further led me to realise that the same mechanical effect can be utilised prophylactically in the phthinoid chest for mobilising bilaterally the upper dorsal spine by an alternating right and left treatment, and also for increasing the range of the upper vertebro-costal articulations. This shows that the preventive treatment of the phthinoid chest, aimed at by Freund, need not be of an operative nature, but may be worked at, with special success in the plastic stage of youth, as an orthopædic, and at bottom, a spinal question.

For Treatment.—As this is a double-edged weapon, the art of its safe and successful use will have to be studied clinically. It is obvious that the scope both of efficiency and of safety will be greatest at stages which least depart from the pretubercular apex conditions. It is also clear that, whilst the strain of breathing unilaterally by a voluntary and forcible effort might be detrimental, for instance, in the early open stage, the same patient might derive considerable apex benefits without any serious risk, from the gentle and smooth expansion induced by the application to the sound side of a *minimal pressure in recumbency*. As "open air" is regarded as the chief curative agency, it is not unreasonable to expect it to be beneficial if it could be brought with safety to the actual seat of the disease; and this seems to be fairly safe both in the closed stage and in the earliest open stage. But that main question, I repeat, must remain *sub judice* for searching clinical investigation.

THE MODIFICATION OF COW'S MILK FOR INFANT FEEDING.

By D. M. BARCROFT, M.D., Ch.B.Edin.,
Physician, Margaret Street Hospital for Consumption, London; and Clinical Assistant, Mount Vernon Hospital; late Resident Physician, Royal Hospital for Sick Children, Edinburgh.

THE view is sometimes expressed that all the work devoted to the modification of cow's milk for infant feeding is labour lost. It is urged that cow's milk, pure and undiluted or unmodified, is quite appropriate for the human infant and is capable of being digested. This view is upheld in a recent paper by Dr. Cameron (*British Medical Journal*, April 26th, 1913). It is, of course, not new, and has been before the profession since Professor Budin, of Paris, advocated it some years ago. The verdict of general experience is, however, against it, and in the majority of instances, whole milk proves unsuitable, even for normal infants. It therefore seems necessary to insist once again that in general practice it is the casein of the cow's milk which produces the difficulty in digestion, and the cases which are adduced to the contrary show that many infants possess a reserve of digestive energy which allow it to be overtaxed with impunity.

My own experience has been that the successful treatment of infantile indigestion demands a most careful modification of the casein content of the milk. After a trial of several methods, I am convinced that its physiological modification by means of lactalbumin is the most certain of all. The method is the only physiological one because it has been shown that the digestibility of the casein of human milk is due to the influence exerted on it by the large amount of lactalbumin it contains. This accounts for the softness and flocculence of the casein curds yielded by cow's milk to which lactalbumin is added.

I have had the opportunity of using lactalbumin in the form of Albulactin pretty extensively at the Bunhill Medical Mission, and I find that, in cases of indigestion and malnutrition of babies fed on cow's milk, its addition to the feeds causes them to be well digested, instead of being rejected almost as a foreign body. In this way, a number of infants who were losing weight or were stationary in weight and were not thriving, have made remarkable and rapid progress, so that in a few weeks their weight rose to normal, and in a few months they presented the appearance of healthy, well-nourished children.

One typical case may be quoted here. It concerned an infant aged 5 months, who had been breast-fed, but was suffering from constipation and extreme malnutrition, only weighing 6 lbs. when it came under treatment—*i.e.*, less than the average weight at birth. It was quite evident that this was one of the cases wherein the mother's milk was not supplying adequate nourishment. The infant was therefore weaned and was given a mixture of Albulactin and condensed milk. This agreed perfectly, and the child's weight steadily increased. It put on 16 ozs. in 14 days, from March 27th to April 10th. The next fortnight saw another increase of 10 ozs. On June 19th, the weight was 9 lbs. 2 ozs., and on July 3rd, 10 lbs.; the appearance of the child was healthy, and steady progress was being made, despite the severe handicap put upon the treatment by the wasted and emaciated state of the patient and the failure of its assimilative powers when it came under our care.

Incidentally, I may emphasise the fact that, in cases of summer diarrhœa, I find Albulactin and water a very much simpler form of nourishment to place in the hands of the mothers, than asking them to make albumin water.

The merits of Albulactin, from the clinical point of view, appear to be:—(1) Its reliability in cases of malnutrition due to digestive defect; (2) The simplicity of its preparation, which can be safely put in the hands of uneducated people.

The proportion of cases in which no benefit is derived from this treatment seems small, so that one might say its applicability is all but universal in this class of cases, and I may certainly say I have tided a good many infants over a period during which, it is doubtful if, treated otherwise, they could have been kept alive.

RE-ALIGNMENTS IN GREATER MEDICINE. (*a*)

By HARVEY CUSHING, M.D., F.R.C.S.Eng. (Hon. Causa),

Professor of Surgery, Harvard University.

Mr. President, Ladies, and Gentlemen,—Thirty-two years have elapsed—a full generation—since this Congress, under the distinguished leadership of Sir James Paget, last gathered in London. Among the participants on that occasion were five of the immortals in the history of the medical sciences: Huxley—naval surgeon, zoologist, palæontologist, educator, philosopher, public servant; Virchow—pathologist, anthropologist, archæologist, statesman and sanitarian; Pasteur, the chemist; Lister, the surgeon; and Koch, the bacteriologist—among the foremost contributors of all time to the welfare of their kind. On the foundations which these men laid—a new conception of biology and man's place in nature; the doctrine of cellular pathology; fermentation and immunity; wound healing without suppuration; bacterial diseases—a transformed medical edifice has been erected. Methods of investigation, the direct outcome of those which they evolved, we will still employ; weapons which they devised are still, and always will be, effective, not only in a hand-to-hand conflict with individual examples of many of the disorders to which man and the animals needful to his existence are exposed, but better still in their prevention.

It has been a seeming paradox that the medical profession has so consistently endeavoured to make of the world a place where there is a constantly lessening need for the medical man. He is, indeed, already feeling the effect of these efforts, and as he becomes more and more a servant of the public health, and less and less a prescriber for individual ills, he philosophically accepts and humanely welcomes this outcome of medical discoveries which the experimental method has already given and will increasingly continue to give. Disorders which gave bread and butter to our predecessors are disappearing, as small-pox disappeared after Jenner. One injection robs diphtheria of its terrors, another, meningitis. Typhoid fever, which once replenished the doctor's autumnal pocket-book, is now looked upon as a civic disgrace, and where it exists or is likely to break out protective vaccination is performed against it. Tuberculosis is everywhere fast coming under State care, and the widespread campaign against the disease, in which those outside the profession are taking no insignificant part, is gradually lessening its ravages. The health of children attending the public schools is supervised by appointed officers; district nurses and the social service worker visit the homes of the sick and assume duties which the hospital physician long neglected; a privately endowed commission takes steps to eradicate hook-worm infection from a whole zone of the globe; an organised Red Cross Society, with Government affiliation, steps in in great emergencies; Governments see fit to pass insurance Acts which make public officials of the profession at one sweep. Dr. Pound, of Cure Lane, is being superseded by his young disciple, Dr. Ounce, of Prevention Street.

THE VALUE OF ANIMAL EXPERIMENTATION.

In the search for biological truths the God-given privilege of becoming obvious benefactors to their species comes to but few men. No one of the countless inquisitors of nature knows whether the mantle of recognition will fall upon him—or, for the matter of that, especially cares, provided he be given the personal satisfaction of having taken a step forward in knowledge, no matter how trifling at the moment that step may appear to be.

To whom is chiefly due the expectancy of recovery for the consumptive? Is it to Leuwenhoek and the microscope; to the father of Lister and to Abbé, who perfected its lenses; to René Laennec and his stethoscope; to Sir William Perkin, whose experiments with the coal-tar by-products furnished the necessary colour reagents; to Villemin, who demonstrated the communicability of the disease; to Koch, whose genius made possible the recognition and cultivation of the organism; or to Ernest von Leyden's propaganda in Germany and the United States; to Trudeau, himself a victim of the disease, through whose precepts and example tuberculosis has been moved into the open, where it is being effectively attacked in a campaign of education shared by laymen, Legislature and physician alike? Unquestionably, through experimentation on animals the most important step in this progress

---

(*a*) Abstract of the Address in Surgery delivered before the Seventeenth International Congress of Medicine, London, 1913.

was made—the discovery of Bacillus tuberculosis and its identification as the causal agent not only in pulmonary consumption but in many "strumous" and "scrofulous" disorders which puzzled our forebears.

Where will lie the chief credit for the approaching victory over the great social scourge, which, since its outbreak in Columbian times, has undermined the vigour of the race? Will it be with those earlier men who gave us the tools of research—the microscope, the culture media, and the colouring dyes; with Schaudinn, who discovered the spirochæte; with Wassermann and the possibility of a chemical diagnosis; with Metchnikoff, who successfully transferred syphilis to the ape; or with Ehrlich, who, by his original methods has had the triumph of synthetising a drug possessing a special affinity for the infecting organism but leaving uninjured the tissues of the infected host? There has been nothing heretofore comparable to this relentless, persistent, certain elaboration of a chemical compound which at a single dose may destroy within the living tissues the organism of a dread disease. Before it all past discoveries of therapeutic agents must make obeisance—even Jenner and vaccinia, Pasteur and the attenuated virus, Kitasato, Behring and the elaboration of the antitoxins.

To whom is due the approaching transformation of the tropics into a possible habitat for civilised man? Again, a series of investigators on investigators' shoulders, until Theobald Smith, in the case of the tick-infected cattle decimated by bovine malaria (Texas fever), in 1893, showed for the first time that a parasite might be an essential intermediary host in the transfer of a disease from animal to animal. Promptly all blood-sucking parasites of man became objects of suspicion, and ere long convictions followed—first in the case of filaria by Manson, then Ross's demonstration that the mosquito is also an essential link in the cycle of "million murdering" malaria—a discovery which was made possible through his studies of infected birds. But when it became necessary to establish unequivocal proof in the case of man, the younger Manson, and Warren, of the London School of Tropical Medicine, did not hesitate to submit themselves to the bite of infected mosquitos sent for the purpose to England from the Roman Campagna. It is hardly possible for one unfamiliar with the experimental method and its necessary tedious controls to conceive of the patient, unflagging, time-consuming labours on the part of many investigators the world over, often conducted in most unhealthy districts and in the very shadow of death, which step by step were required to lead to this final demonstration—labours which in review seem almost beyond the possibility of accomplishment. The discovery of the malarial plasmodium of the blood, the determination of its several varieties, the study of the sexual cycle of its development, the observation of the changes in the stomach wall of the mosquito and the final lodgement of the sporozoites in the glands of the proboscis, the recognition of the particular species among the many genera of mosquitos concerned, the establishment of the fact that the female alone is the active agent, the finding of the length of time necessary for infectivity—each step, whether made by Frenchman, by Italian, by Canadian, by Englishman, or by German, was a triumph of the spirit of research, and no great objection is raised if, in the process, the mosquito, bird, and man are the subjects of experimentation.

Large sums of money have been wisely devoted to the prevention of cruelty to animals, and much good has been done in the past, but by a strange process of evolution most of those now entrusted with these funds, instead of grasping the opportunity to advance knowledge of the diseases of animals, have devoted their energies to opposing such advance as may be undertaken for the sake of man at some expense to animal life. The future offers a great opportunity for these societies, whose capital is now largely expended, on the one hand, in the wholesale sacrifice of stray and diseased animals, and on the other in destructive criticism of the methods of those they call vivisectionists; for by constructive investigation and by the employment of the same methods which have been elaborated by those whose primary object is the study of the diseases of man, they may become as great benefactors to animals, and incidentally to man, as the medical scientists have been to man and incidentally to animals. There could be no better outlet for the present wasteful methods of many of these organisations than the establishment of veterinary hospitals in which modern methods of treating disease could be employed, further investigations made, and students of veterinary medicine taught—the three great functions of any hospital; and there is promise in some communities that this wise step may be taken.

The Relations of Medicine and Surgery.

Billroth said some thirty years ago, "Die innere Medicin müsse mehr chirurgisch werden," and this seems to be what is taking place. Before Billroth's time it was largely internal medicine versus external surgery, for operative measures were necessarily confined to the exposed parts of the body; the visceral surgery of to-day—the larger part of the present surgeon's work, in the inauguration of which Billroth himself played no inconspicuous part—was then inconceivable. We still retain many of the traditions of those earlier days, days when a pure craftsman, steeled to act in the face of unanæsthetised suffering, amputated, removed surface tumours, ligated vessels, cut for stone, and treated fistula and a few other ills with an unerring hand and unbelievable speed. The high-road to surgery was through the anatomical dissecting room, and in these surroundings the operations of surgery were then, and are still, largely taught, with the result that the rule-of-thumb operations of one generation are handed on to the next, who will never use them, owing to the extraordinary progress ever making in these measures due to methods of asepsis and the increasing knowledge of surgical possibilities. To-day an individual of wholly different temper from the surgeon of old ventures to do operative work, and the essentials for his training are of an entirely different order. Descriptive anatomy, useful as it may be to him, is no longer a prime requisite in the terms of the past generation, but his knowledge of visceral physiology and pathology must be broad, his observations of asepsis unimpeachable, his skill in hæmostasis and handling of the various tissues delicate and painstaking. As a training ground the anatomical dissecting room fast gives way to the experimental laboratory. In the breaking up of greater medicine into its clinical specialities, the primary cleavage gave us physician and surgeon, with medicinal versus manipulative forms of treatment as their essential distinctions. Chiefly on anatomical lines each of these major subjects has broken up into a second or even a third order, but in the case of these further subdivisions it is to be noted that there is an inevitable tendency for operative therapy to become attached thereto, so that we have the ophthalmic or aural or laryngological surgeon, the gynæcological, orthopædic, genito-urinary, or neurological surgeon, according to the direction whither opportunity or training or inclination may have led. Even the obstetrician—the half-brother of the physician and surgeon—reaches out for the operative side of the diseases of women, with the complete Frauenklinik in mind. And what is happening in these specialities is an indication of the tendency in the two major branches; for internal medicine and surgery, as the treatment of disease grows less empirical, unquestionably tend to converge.

Modern Science and Experimental Methods.

"Surgical instinct" and the "educated touch" have been overworked shibboleths which have stood in the way of many innovations, particularly those which concerned the introduction into practice of instruments of precision. As told in rhyme by Oliver Wendell Holmes, fun was poked at Laennec and his new-fangled toy, the stethoscope. Probably Floyer heard a protest against the "pulse watch" and Wunderlich against the thermometer; only yesterday it was raised against the instrumental measurement of blood-pressure. Had not the hand been industriously trained to estimate the degree of fever by contact with the patient's brow, and the fingers the quality of the pulse at his wrist? Even the Roentgen ray brought misgivings to those skilled in the elicitation of crepitus from fractured bones. The tendency to disparage the so-called accuracy of "scientific" attitude in medicine and to make much of the "practical" doctor or surgeon who is superior to the microscope and other laboratory accessories is rapidly passing. As I have said, the application of surgical principles, whether in laboratory or clinic, is constantly becoming more general. The slipper of surgery has been found to fit that Cinderella of medicine, experimental pathology, whose coach now has devoted outriders representing all departments. In consequence of this lessened departmental insularity, all react far more quickly than heretofore to a ray of light disclosing some new aspect of disease, just as they do to some novel method of study which reopens a door long closed against profitable investigation. The glands of internal secretion and their inter-relations, brought to the fore primarily through the clinic; the principle of intravital staining, with all its promising ramifications, introduced by the experimental therapeutist; the studies of cellular physiology which refined methods of tissue-staining promise to make so fruitful; and the growth of tissues in vitro by the experimental anatomist; these occur as immediate illustrations. To-day the clinical acumen of the practitioner, experienced though he may be, has given way to a chemical test by a laboratory expert, and only when the disease is thus proved to exist is a diagnosis accepted. The discovery of the spirochæte and the study of its biological habits have taught us that in certain parts of the body, especially the central nervous system, the organism is not accessible to the former methods of treatment, or, indeed, if reached, that it may have acquired an immunity and resistance toward the very drugs supposed to destroy it.

Let is suppose that the malady has taken the form of a cerebral gumma. The patient has headaches, and there is a suspicious clinical history. What is required? A lumbar puncture, a cytological study of the fluid, and the Wassermann test requiring one specialist; an ophthalmological and perimetric examination needing another; a neurologist certainly, for a careful study is necessary to determine if possible the situation of the lesion; probably, too, a Roentgenologist; and in the end, perhaps, another to administer salvarsan; or, in the case of a non-absorbable fibrosyphiloma, as likely as not an operation will finally be needed. And this for what was yesterday a simple problem, easily faced by the practitioner single-handed! Thus, scientifically accurate diagnostic measures and a new form of therapy requiring blood-letting and manipulative skill make a craftsman even of the syphilographer. This is a far cry from a written prescription, a bottle, and spoon.

No, the practitioner cannot be chemist, neurologist, bacteriologist, ophthalmologist, radiographer, surgeon, and what-not rolled into one, and do effective work. The Jonathan Hutchinsons of the profession are, alas, rare.

These, then, are some of the transformations and realignments which are taking place in medicine, and which, directly or indirectly, have come through the great contributions made a generation ago by those with whose names this address was introduced; the public is not only awake to the great developments in medicine which animal experimentation has made possible, but ready to participate in their application for the general welfare; the physician at large, the valued family adviser, is reaching out toward the important problems of hygiene and preventive medicine, while the individual patient, as the complexities of disease unravel, needing more and more specialised and more and more surgicalised treatment, is gravitating toward the modern hospital; the departments of the preclinical medical sciences, which formerly existed in splendid isolation, find their fences down, owing to the levelling influence of experimental pathology; hospital organisations are undergoing changes which will ultimately require the full time and continuous activity of those who serve them for the benefit alike of student, of science, and of patient. The kaleidoscope of medicine is turning; these are merely some of the present rearrangements of the images as I see them—new patterns from original fragments—for "Is there anything whereof it may be said: See, this is new? It hath been already of old time, which was before us."

RECENT WORK UPON HYSTERIA. (a)

By TOM A. WILLIAMS, M.B., C.M.Edin.,
Washington D.C., Memb. Corresp. Soc. de Neurol. de Paris, and Memb. Corresp. Soc. de Psychol. de Paris, Memb. Assoc. de la Soc. de Med. Ment. Clin.; Neurologist to the Epiphany Dispensary, etc.

Whether hysteria is determined, as Breur (1) thinks, by the occurrence of peculiar dream-like conscious states with a narrowed association capacity, and whether these are purely due to psychically painful experiences as argued by Freud (2); or whether, following Janet (3), hysteria is to be summed up as a weakness of the power of associating impressions; or whether it is an actual splitting of consciousness which more or less divides its victim into the exaggeration of manysidedness, known as multiple personality (Sidis) (4); or whether, with Sollier (5), we conceive hysteria as an inopportune sleep or numbness of a part of the cerebrum; all clinicians agree with Babinski (6) that the most conspicuous and invariable characteristic of a hysterical is *suggestibility*.

As nothing is more detrimental to the progress of science than to call by the same name phenomena which differ in essence, it would be eminently desirable that students of the psycho-neuroses should adopt some least-common-measure for the study of each group; and as it seems quite evident that there is a group of very various symptoms, each of which is "susceptible of being produced by suggestion and removed by suggestion persuasion" (7), it is strongly to be desired that differences should be sunk for the time being in order that, by use of a common, unique and unequivocal, and above all ætiological, character we may collect examples by the correlation of which we may hope to penetrate more deeply into the origin of *pithiatism* (8) in general.

That Babinski has fallen back upon a teleological definition (9) of suggestion is to be deplored; for the sense in which he uses the word, that of an insinuation, that is, something evil, is entirely subversive of the essential psychological mechanism that is connoted by it, and so long ago made clear by Bernheim (10). For the essence of implantation of ideas by suggestion is not their evil nature, but the manner of their reception, viz., without full awareness of how they have gained entrance to the mind.

Elsewhere (11) I have tried to develop the difference between this process and that which may be called persuasion, in which the subject takes full cognisance of the manner in which his belief is caused to alter. A man persuaded knows *why he knows*: a person suggestioned *merely knows*. It is the method in which knowledge is acquired by children, savages, many of the uninstructed and the credulous in general. A few examples will make clear the manner in which symptoms are acquired by suggestions in some common types of hysteria.

(See also "Ten Cases of Hysteria Successfully Treated without Minute Psychoanalysis" (*Post-graduate June Medical Annals.* Wash., January, 1912), many of which illustrate the mechanism.)

Case of Hysterical Hemiplegia.—A young married woman, whose appendages had been removed some years before, at which time she had right hemiplegia believed to be syphilitic, was seen with Dr. Thos. Claytor. She had completely recovered until a few days before I saw her.

There was complete anæsthesia and flaccid paralysis of the right side. There was no hemianopsia, ataxia, or tremor, which excluded a thalamic lesion.

(a) Read to the Neurological Section, A.M.A., June, 1912, at Atlantic City. *J.A.M.A.*, Dec. 21, 1912.

The patient could be made to sit up, during which act the abdominal and pelvic muscles contracted coordinately, which they could not have done in so complete an organic paralysis. The tendon jerks were not exaggerated, the abdominal reflex was not diminished, and the great toe did not extend when the sole was stroked. There was no hypotonia, and both platysmæ contracted on forcible depression of the chin. Synergic dissociated movements were absent, and there was no complication of facial, ocular nor articulatory muscles. When palsied arm or leg were suddenly let go, there were contractions of the antagonistic muscles.

The syndrome had occurred after a contrariety, and was quickly removed by the suggestion of gradually re-educating the movements. Four days later the patient shook hands and could walk, in accordance with my expressed expectation; and the patient was then fully apprised of the fact that her paralysis had arisen merely from the idea that she could neither feel nor move the right side. The discussion is too long to detail here (34).

Case II.—*Hysterical Obsession and Phobia.*—After an attack of influenza, a woman returning in a crowded car from a shopping expedition, began to feel much oppressed and in want of air. The heart, enfeebled by the influenza poison, and we know not what others taken as medicaments and aliments, ceased to respond to the call upon it for a more rapid flow of blood, so that aeration could be sufficient, and a faint ensued, with the psychic accompaniments of irresistible terror and dread of dissolution. Never since has this woman been able to bring herself to go alone into a car; the very idea of doing so induces the idea of fainting. She is not possessed by the idea so long as the question of entering a car does not arise; but although she knows her conduct to be unreasonable, she cannot bring herself to act reasonably about going alone into a car.

Discussion of these Cases.—Now, the method of solicitude and sympathy merely reinforces the patient's belief in the validity of the idea for which sympathy is an implicit acquiescence. Still more injurious is direct medical treatment of the apparent physical disorder which results from ideas (12). For instance, a hysterical monoplegia (*i.e.,* a paralysis of one limb induced by the patient's belief that it is disabled) should not be treated by the application of electricity or massage to that limb, nor by the giving of an internal remedy which the patient is led to suppose is capable of removing such conditions. It is very bad practice, too, to pretend to perform an operation upon the patient who believes, *e.g.,* that she is inhabited by a lizard she has swallowed. Sometimes, it is true, a symptom disappears through the suggestion involved in such a procedure; but it does so in a small proportion of cases only, is a pure chance, and does not touch the cause, while by ascertaining and removing the root, we can generally cure permanently, as regards the present symptoms at least.

An illustration of the method is afforded by one of my cases of traumatic neurosis, for this condition is merely the expression of an induced fixed idea of a disability which is recovered from as soon as the pathogenic idea is disposed of.

Case of Traumatic Neurosis.—After bruising his back by a fall from a car, a railroad brakeman remained for six months very lame, and the sensibility of the lower limbs appeared to be lost. His tint had become sallow, and he was dyspeptic and emaciated; he was sleepless, sad, and cried much. The neurological examination (reported with the case, *Med. Record*, October 2nd, 1909), showed that there was no destruction of the nerve elements. The disability was shown by psycho-analysis to be a function of the false fixed idea, induced by the belief derived from his environment that such symptoms as he showed could and should follow such injuries as he had had. One sitting sufficed to begin the correction of this false notion, and he himself completed the persuasion, and was able to return to work in a month, as I had predicted (13).

In Children a Case.—Now, the suggestibility of children is much more labile than that of such cases as I have cited, for while they are very susceptible, they do not usually hold tenaciously, and are easily diverted from their loosely-fixed ideas, when morbid. (See *Archives f. Pædiatrie,* Feb., and *Brit. Journ. Chns. Dis.,* Feb.). For instance, it is perhaps unique for a girl so young as eleven to believe that she is utterly unable to eat, and to do so strongly enough and long enough to overcome the instinct of hunger to such an extent that she had to be removed for treatment to the hospital, where in the Salle Pinel of the Salpetrière, Professor Dejerine built up her emaciated body by generous feeding, and at the same time undid the false notion she had acquired from her elder sister, who had been a patient in the same place. (14)

Trophic Symptoms are not Hysterical.—This manner of causation so far has not been proved capable of directly producing œdema, erythema, urticaria, ulceration, hæmatemesis, hyperhydrosis, dilatation or inequality of the pupils, tachycardia, muscular atrophy, nor any such vaso-motor and trophic disturbances which were formerly included in hysteria; and it is now clear that such cases are due to physical causes (15) which are becoming less and less obscure as pathological data accumulate. Many of these symptoms are angio-neuroses (16), which have nothing to do either with suggestibility nor other psychic processes, even emotionalism.

Similarly, the best observers believe that hyperthermia cannot be produced by psychic means at all, although it is now quite clear that a rise of temperature often ensues after the psychic excitation of patients suffering from hyperthyroidism (17). This, however, is due to the sudden determination of increased secretion of the thyroid gland, which may sometimes even cause death. But if the patient lives, the temperature soon subsides, and its rise cannot be considered psychogenetic in the full sense.

Similarly, the arrest of digestive secretion induced by bad news occurs in consequence of the emotion caused by them. It is strictly temporary (18), unless the emotional state is constantly reinforced from without or within. When the modification endures, we have perhaps the only example of a permanent physical modification of a function not under the control of the will of which the source is directly psychogenetic. Although its genesis is emotional, yet as the motion may be determined through an idea, and the idea may be implanted by suggestion, it may be sometimes legitimate to attribute to hysteria this form of mental anorexia (19), in spite of its manifestation through a portion of the nervous system which is mainly autonomic. That the autonomy of the gastric secretion is not complete, however, has been clearly shown by the researches of Pawlow (20) and Cannon (21); and as no such dependence has been shown concerning permanent changes in the skin and mucous membranes, a better type of evidence than heretofore must be brought forward to convince us of the psychogenesis of the cutaneous manifestations at one time described with hysteria.

Malingering.—I do not wish to do more than remind the reader of the large number of cutaneous eruptions, œdemas, fevers and so on which have been produced by simulators, both hysterical and not. The desire to deceive for the sport it brings, or from no apparent motive, is a symptom which may have nothing to do with hysteria. Dupré has created (22) the term mythomania to characterise this group of abnormality, and every medico-legal expert and many a schoolmaster knows it well.

The number of those cases which "could not possibly have had access to any means of provoking their symptoms," only indicates the looseness with which such negative evidence is accepted, as, for instance, in a case of alternating mydriasis which I observed in Babinski's clinic, for though the patient's father indignantly repudiated the mere statement thereof, yet it was found that his daughter had been placing in her eye drops of an atropine solution filched from her employer.

Another man confessed to concealing a syringe in the rectum, and in a moment of excitement an evacuation revealed two. Of course, mythomania, a type of moral degeneracy, or of lack of adaptation, a weakness which resorts to trickery, may be, and generally is, accompanied by suggestibility; so that, academically speaking, a deliberately produced lesion simulating spontaneous disease which the patient is trying to imitate may deserve the term hysteria; for, of course, imitation is one of the forms of suggestion. Intermediate in type are the imitations of disease seen so frequently in the more ignorant hospital attendants and patients. These, too, often figure as hysterics; and, indeed, this symptom may be induced by suggestion, as in the case of nurses and patients who inflict upon themselves eruptions, ulcers, swellings, or complain of palsies, contractures, vomiting of blood, etc., by the imitation of those they have seen in the hospital. The mental debility which allows them so puerile an outlet for their activities permits them also to receive suggestions without criticism—*i.e.*, to be hysterisable.

Stigmata are Artefacts.—Unless their methods of examination act to remove the symptoms before they can be found, so to speak, the experience of Bernheim (23) and Babinski (24) clearly shows that both anæsthesia and contracted visual fields originate in unconscious suggestions of the medical examination, in the vast majority of cases. For over twelve years neither observer has found a contracted field in a patient not previously examined.

Either explanation is consistent only with extreme suggestibility.

GENESIS OF HYSTERIA.

The cause of this has not been enquired into very profoundly either by Babinski or Bernheim, but attempts to account for it have been made by others. The explanation which commands the most notice is that of Freud (25), who ascribes it to a mental conflict which has arisen as a result of painful experiences in early childhood. It is unfortunate that so many of his followers have attributed the significance of this explanation to sexual insults in themselves; for Freud distinctly states: "I passed a good way beyond my former point of view—correct the imperfections, displacements and misconceptions. My former meagre material gave a great many cases where sexual seduction played the main *rôle;* I overestimated the frequency of these. I have since learnt to explain many as an attempted defence against the reminiscence of masturbation." Freud has also disclaimed his conception that hysteria is predisposed to by passive behaviour in these erotic events, while active behaviour results in compulsion neurosis. He still, however, believes that the elements of constitution and heredity really mean "sexual constitution."

So that, although Freud still attributes the psychosis of obsessions and phobias (26) and also the anxiety neurosis (27) to direct perturbations of the sexual function, he no longer imputes to this immediate cause what he calls hysterical symptoms, which he agrees are purely psychogenic. But he attempts to explain the state of these patients by the subconscious (*a*) effects of a forgotten circumstance—a purely psychic trauma (*a*), which the patient has been unable to amalgamate with the rest of its mental life, and which he has succeeded in forgetting on account of its painful nature. Its memory can, however, be recalled by his "free association" method, which consists of placing the patient in a tranquil attitude and inducing him to think aloud about the events most nearly connected with his illness, and urging him to push his introspection further and further back. Other means of recalling lost memories are the association test of Jung (28), and the psycho-galvanic reaction of Veraguth, with which Jung (29), Petersen (30), and Sidis (31) have largely worked. Still better known is the method of hypnosis. The hypnoidisation procedure of Sidis (32), to the writer, seems very similar to that of Freud.

All of these methods have the common property of abstraction from extraneous stimuli with concentration upon the trend of thought required by the physician; and in this respect the method of simple anamnestic interrogation is in many cases just as informative *when conducted with skill and tact.* But it fails in respect to the vividness of the recollections which it recalls. The patient here *talks about* his experiences. In hypnosis and other distraction methods the patient *re-enacts* his experiences as he would do in his dreams. In the treatment of grand hysteria, Sollier (33) has lain great stress since 1892 upon the need of the patients in hypnosis to carry themselves farther and farther back among their infantile experiences. While Freud says, "There is surely something more, think," Sollier urges "Allez plus loin, plus en arrière." To judge by his early case reports (for he no longer considers it "worth while to publish them"), the results of his treatment do not show any inferiority which would lend countenance to the claim of Freud's followers (*b*) that their method of psycho-

---

(*a*) *The Subconsciousness.*—This term has been much abused, but its consideration here would lead us too far; suffice it to say that the submerged memories which determine much of our conduct and beliefs can scarcely be said to act in themselves, but rather by the inferences which are drawn from them, and of which the subject is more or less aware, although he will not always admit their influence. His denial, however, is largely like that of a woman that she seeks a husband or of a politician that he is looking for an office. If not merely conventional, the disclaimer is dictated by ashamedness or by a dislike for the confession which is so good for the soul. A frequent declaration of my patients is somewhat as follows: "I don't know why I am talking like this to you; I would not dare thus to reveal myself to anyone else; not another person knows these things that I am telling you," etc. Now, this confession has not been obtained through hypnosis nor other special means. In one sense, the patient does not explicitly feel her revelations until they are completed. But could the fact that her ideas require for clear formation their focussing into a definite statement justify us in calling them subconscious? I think not, for the process does not differ from the clarification of thought engendered by writing, speaking or other attempts at precision of ideas which before that may have been only in adumbration. Such was the means by which a patient of Flournoy (40) (whom some clinicians would have called a hysteric) made clear to herself, for her salvation from suicide, the thoughts which lingered in the back of her mind, but which had been temporarily overshadowed by her despair in having to repulse her child for fear of infecting it. In a dream state she had a vision of a dear friend leading her away from the water in which she was about to throw herself. Now, although the conversation she imagined was purely hallucinatory, it was none the less valid as a representation to herself of ideas which took this method of formulation. The mechanism is commonly used by automatic writers, crystal gazers, etc., who have recourse to a consultation with an oracle, which they sometimes believe to be extraneous in source. Others, however, are equally mystical in that they conceive it to be another self, subliminal or subconscious. By these means, the suggestive influence of their lucubrations is greatly increased; but psychologically, the process is exactly the same as that of discussion, thinking aloud, or reflection. "Coconsciousness" is the name given by Prince (41) to some of these states, which he believes to be completely dissociated from the personality. As a rule, however, any disunion of separate streams of thought can be quickly overcome by simple means, provided that the observer does not acquiesce in the patient's reluctance to face certain unpleasant facts, which he often declares "he does not know," and soon persuades himself that "he cannot know."

(*a*) But is it really necessary to invoke a specific trauma to explain hypersuggestibility? Is it not a common experience that when the mind is strongly pre-occupied by any course of thought absent-minded acts are the rule? What are these but immediate reactions to stimuli while the reflective processes are occupied by the dominant train of thought? In a sense, that which pre-occupies the patient is dissociated from the stimulus to which he reacts while absent-minded, and indeed from the events of daily life, as long as the pre-occupied state persists. To this extent, hysteria is a phenomenon of psychological dissociation. This explanation of its mechanism is not very different from what Freud has called conversion. Psychologically the process is the same as that occurring in suggestion.

(*b*) It has been alleged that Freud and his followers inevitably guide the revelations of their patients towards the ideas of which they are in search, and that they strongly influence the content of the patient's thought. This is tantamount to saying that some at least of the patient's ideas arise from the suggestion of the examining physician. When one remembers the ease with which even physical symptoms are suggested, this objection has *à priori* much force in so delicate a field as psychological investigation. The controversy can be settled only by impartial and well-trained observers working with Freud's method. At all events, it is becoming more and more clear that sexual traumata of early childhood need not produce a psycho-neurosis, and that, at least, the active cause of psycho-neurosis in some patients appears quite unrelated to the sexual life. One is tempted to believe that the enthusiasm of discovery has tended to an exaggeration of the weight of this ætiological factor, especially in an age where a reprehensible prudery has prevented its due consideration by the profession at large. But it is significant that analysis is a *sine qua non* in obstinate cases; for these recalcitrant cases are just those which find their way to Sollier.

Diagnosis must be Genetic.—Now, from these facts, it should be apparent that a hysterical symptom, being one induced by an idea derived from suggestion, can only be removed with certainty and permanence by a preliminary finding of the causative ideas. Empirical methods are worse than futile; for they merely reinforce the patient's belief that she is badly sick.

The peculiar fact about this pathogenic search is that the mere discovery and explanation of the causative idea of the patient generally may suffice to remove the symptoms it has caused.

But it does not cure the disease. To do this, a course of re-education (34) of the patient's hysterisability is needed. This is not always possible in practice, on account of the time and expense required.

But we are now in a position to dispense with some of the elements of this expense. I refer to prolonged isolation, over-feeding, massage, electrical applications and special nursing. to which so many hysterics have been subjected on account of the secondary neurasthenic symptoms they have developed..

The means of distinguishing this false neurasthenic state from the really primitive asthenias have been indicated at length by the writer (35); and Bernheim (36), too, has devoted a recent monograph in part to this distinction, which is in short that "neurasthenia is a physical exhaustion, either congenital, toxic or other; and that any psychic symptoms a neurasthenic may present are usually secondary and disappear spontaneously as his condition improves"; unless, indeed, they are maintained through the reinforcement of their suggestion by the injudicious solicitude of doctor or friend, in which case they are hysterical, of course.

On the other hand, the neurasthenic symptoms which are induced by a fixed idea of illness soon disappear when the patient's ideas are rectified, as illustrated by my case of traumatic neurosis, and by many a woman who, when exigencies of her own temper have demanded, has arisen from a sick bed into the full activity of normal life.

Isolation Needless or Harmful.—The fetish into which the Weir Mitchel treatment has been erected has been demolished by the recent work of Levy (37), who shows the Dubois' way of conceiving the relation of body and mind (38) does not differ from the dualism he imagines he has transcended; and Levy points out how grossly and naïvely Dubois exaggerates the influence of the psyche over bodily conditions. In this respect Bernheim has long transcended his former views regarding the power of hypnotism: he has done so by acquiring a clear notion of the difference of psychogenic and somatogenic nervous symptoms.

Now, Levy shows that true isolation should not be a physical removal from environment, but a moral substraction from fears, preoccupations, obsessions, morbid ideas; and that this can be done even better in the usual surroundings than during isolation. Even that bugbear of the physician, the patient's friends, can be converted into an aid instead of a hindrance where intelligent people are concerned. The chief appeal for the method of isolation is the power it gives the doctor to "persuade" and reason with his patient. But even this Levy believes to be of little use unless an opportunity is given the patient to practise the resolutions he forms; and as he cannot do this while isolated in bed, such treatment is injurious, for his best intentions will wither like a hot-house plant in the open when he has to face the stresses of his life. One might as well learn to swim on the couch or to play the piano by listening to lectures and discussing them.

Another fault of the Weir Mitchel treatment of psychoneuroses is its stress upon details: the really important thing is that the patient thoroughly grasp the principles upon which his disorder depends, and that he practise himself under the physician's direction in learning to avoid the pitfalls which life affords for his neurotic constitution. He must learn his own psychology and the dependence of his bodily health upon his mental state; but he must also learn that body and mind are only two sides of one thing, and that bodily conditions react upon his mental state, and that susceptibility to suggestions may be vastly increased by fatigue, dietetic errors, or any cause of intoxication of the neurones. Even prolonged mental stimulation, by the excessive interest which does not know when to stop, may be a source of a neuronal state favouring suggestibility.

Beautiful examples of rational as opposed to empiric methods of treating hysteria are the following:—

Case IV.—A woman, æt. 28, whom I saw in February, 1911, with Dr. Hardin, to whom she was referred by Dr. Maphis, of Warrenton, Va., in the preceding June, had had a chill after which she cried. The next day she felt very weak, and the next day she had pain in the knees, she thinks only in the left, with hyperæsthesia. There was also, she says, tenderness of the lumbar spine, and later on in the groin and hip. She was treated by massage, and for four months was relieved. About Christmastime these pains recurred when her sister visited her. There were then nausea and persistent dull pain in the knees, which caused her to groan in her sleep.

Examination was negative, except that there was great hyperæsthesia of both knees and one arm. Also the right abdominal reflex was absent, and the adductor reflex was exaggerated on the same side. I decided that the case was psychogenic, and that afternoon attempted psychanalysis to seek the origin of the psychalgia. I found two suggestive incidents, one being the visit of a sister on the second occasion, the other being the fact that when first attacked her brother had a severe hysteric spell. He had consumption, which she feared. Another fact perhaps significant was that she had been two weeks in a newspaper office during its change of ownership, alone with the man in charge much of the time.

As she could stay in Washington only a short time, I concluded that it would be better to remove the effects of whatever had been the source of the hysteric symptoms of psychomotor discipline than to try to pursue psychanalysis, which might be unfruitful in the short time at her disposal.

Method.—As the least approach towards the patient's knee would set up a spasm of terror, during which adductors, hamstrings and extensors went into spasm, I began a course of gradual habituation, first to the approach of a person's hand toward the knee, later to manipulation of the patellar region, followed by pressure on it. A sister attended her in hospital and helped her to accomplish these exercises several times each day. In this way she taught herself in a few days to control the muscles around the knee-joints so as to prevent them contracting when her knee was touched. The pain ceased when the spasm did, as it was in part maintained by the latter. Then her alarm vanished, as there was no reason for it; and she was satisfied that her pain lay in her own power to control. The dangers of prepossession by a fear, in conjunction with the mental vacuity engendered by lack of occupation, were explained to show the genesis of false fixed ideas regarding disease, and she was told how to avoid them.

She returned to Virginia in a week well, and has remained so for nearly two years.

Case V.—A further case illustrating the effect of

French observers, of whom this fault cannot be alleged, do not attach preponderant importance to the sexual factor in neurotic disturbances. The free association of thought at which Freud aims during psycho-analysis is believed by him to resemble that of the dream state. But neither during the dreams of sleep nor still less in day dreaming is there that complete suspension of auto-critical judgment one might suppose were only the fantasticalness of dreams considered. Even the bizarre images of the dream are symbols of a latent psychic content often unsuspected by the patient. In the same way he interprets a hysterical symptom as an unconscious conversion by the patient into a physical symptom of a thought which, in its naked form, he could not bear; and it is in finding of these that psycho-analysis is so useful. The suppressed experiences are particularly active in dreams. Hence analysis of these is most useful as a short cut to an understanding of much which the patient's waking mind is ignorant.

proper discipline is that of a barking, roaring and bowing tic removed in one day. The patient was referred to me by Dr. Thomas Charles Martin. He had been treated for rectal ulcer for some months. He had recently removed to North Carolina, but wanted to come back to Washington. It is possible that this had something to do with the development of his condition. I was asked to see him, because when he sat down he would utter a series of barks, while at the same time the trunk would go into a spasmodic flexion. When he was stripped, there were seen strong abdominal muscles and regular bowing of the whole body along with this barking, grunting noise.

Psychanalysis showed that these attacks had begun suddenly in North Carolina at 10 p.m. three months before. The significant fact was that he had eaten sandwiches which had been sent to him by his parents in Washington, and that he had been thinking despondently before he went to sleep about how nice it would be to be in Washington. He was also thinking considerably about his intestines having been under treatment by lavage. The exact psychologic mechanism was not discovered, however.

Method.—I thought it better to remove the effects rather than necessarily to discover the details of the genesis of his tic. So I instituted a course of psychomotor discipline. The tic, which at first had come only when he lay down at night, had later occurred whenever he sat down also, and thus made life a burden. So we began by exercising in the sitting position. I placed him in a large chair, reclining, showing him how deliberately to contract the recti abdominis, and made him perform a series of respiratory movements, as well as the series of rectitory movements. After a few moments he became capable of contracting either the recti or the diaphragm. That being accomplishment enough for one sitting, he was asked to come back the following day. He went home and tried the exercise while recumbent at night. The result was that he came back next morning and said, "Doctor, I am cured. I did not have any spell last night." Two days later, however, he relapsed. But after another discipline he remained well.

Thus it is simple to remove the effects in this rational way. It is so much better than the rough suggestion often attempted. For example, the last patient had been treated by electricity, which he was assured would remove his spasms. When this failed he was treated by direct suggestion. When this failed he was treated by "the most marvellous remedy known," a drug obtained from some remote country, which was guaranteed to cure. Thus, the most powerful suggestions failed in a case which was in origin suggested and conformed to Babinski's definition of hysteria, "susceptible of production by suggestion." A motor habit had been formed, and the removal of all habits requires re-education of the patient's volition.

Indeed, it is only by its action on the will that suggestion ever succeeds.

Now, although hysteric symptoms are always psychogenetic and have a mechanism the knowledge of which enables the clinician to penetrate to their origin, yet hysterisability varies with bodily states (39), so that the treatment of hysteria cannot safely be left to those laymen who have arrogated to themselves the title of psychotherapeutists by an assumption which is justifiable only to the minds of dualists and those who attach no validity to the old adage which becomes more and more true as our psychologic knowledge broadens and deepens, *mens sana in corpore sano.*

The application of the principles described in this article is shown in ten cases which I recently reported.

OPERATING THEATRES.

ST. THOMAS'S HOSPITAL.

Carcinoma of Undescended Testis.—Mr. Corner operated on a man, æt. 37, who had been admitted with the following history: The patient first noticed a lump in the lower part of the abdomen about a month previously. It was then of considerable size, and his attention had been drawn to it by pain in the left groin running round to the back. Since this time, however, there had been very little pain, and the tumour had caused no inconvenience. There had been no difficulty in micturition or in defæcation, but the man had recently lost weight.

On examination the patient was thin, but did not look anæmic. The lower part of the abdomen was protuberant, but the skin was not inflamed. On palpation a hard painless mass could be felt in the abdomen to the left of the middle line and just above Poupart's ligament; it was apparently in the abdominal wall, but was not attached to the skin. The fingers could be insinuated under the upper end, which was well defined and somewhat irregular. On the left it was limited by Poupart's ligament; on the right it extended nearly as far as Poupart's ligament on that side. Below it reached the symphysis. It could be moved laterally to a slight degree, but not vertically. A soft mass could be felt in the left inguinal canal; this was thought to be the testis, which had not descended. It did not, however, give testicular sensation, and, as far as could be made out, was not connected with the mass in the abdomen, which last could also be felt per rectum in the region of the prostate. Another mass could be felt deep under the left costal margin; this mass was nodular, and did not move with respiration. A median incision was made below the umbilicus, and the growth was easily found in the anterior abdominal wall. As there was a great deal of glandular affection it was impossible to remove the tumour, which had the appearance of a sarcoma. A second incision was made in the left groin, parallel to Poupart's ligament. No testis was found in the inguinal canal;

the mass that had been previously felt turned out to be a loop of the vas deferens which had come through and then returned through the ring. Both wounds were closed in the usual manner. The patient's temperature only once rose above the normal, and that was on the day following the operation, after an injection of Coley's fluid. It was remarked that his arteries were atheromatous, but there were no cardiac murmurs.

The result of a pathological examination of a specimen was that the tumour was a carcinoma of the testis.

HYDATID CYST ATTACHED TO THE LEFT LOBE OF THE LIVER BY A LONG PEDICLE.—The same surgeon operated on a girl, æt. 3 years and 3 months, who had been admitted with the following history: Two days before, in the morning after defæcation, she complained of acute pain in the right iliac fossa, which continued until she was brought to the hospital. In the evening of the day when she first felt the pain she experienced nausea whilst at supper, which feeling continued. She lost her appetite, and the bowels had not been opened for two days. She had been sent to the hospital by a medical man with a diagnosis of appendicitis. After admission the child lay on her back, complaining of pain low down on the right side of the abdomen. Temperature, 101.6; pulse, 130; respirations, 36. Movements of the abdomen equal on both sides. Some rigidity of the recti in the lower half, more on the right side than on the left. No tenderness on palpation, excepting in the right iliac fossa, where a tender mass could definitely be felt. This mass felt fairly soft, but the rigidity of the rectus prevented the outline being absolutely defined. The respiratory and cardio-vascular systems were normal. Pulse good, but rapid.

At the operation the right rectus sheath was opened and the muscle displaced, and a trap-door incision made through the peritoneum. A cyst about the size of a tennis-ball was found in the right iliac fossa, attached by a long pedicle to the right lobe of the liver, by a broad base to the left of the gall-bladder. The surface was everywhere inflamed. There was a moderate quantity of free fluid in the abdomen. The pedicle was clamped and the swelling removed; this was found to be a cyst full of fluid, which was clear and colourless. The cyst had a thick, fibrous outer wall with a thin inner lining membrane.

SPECIAL REPORTS.

THE SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE, LONDON, 1913.

SECOND NOTICE.

THE number of receptions, soirées, garden parties, excursions, and other social functions in connection with the Congress was really bewildering, but our foreign guests thoroughly enjoyed themselves, and all the members made the most of the opportunities that presented themselves for having a "real good time." At the closing meeting on the Tuesday, it was announced, in addition to that previously chronicled, that the following resolutions had been sent up by the Sections of the Congress:—

A.—By the combined Sections of Dermatology and Syphilography (XIII.) and Forensic Medicine (XIX.):—

"That, sensible of the ravages wrought by syphilis in the health of the community, and deploring the inadequacy of existing facilities for checking its dissemination, the International Medical Congress calls upon the Governments of all the countries here represented—(1) To institute a system of confidential notification of the disease to a sanitary authority, wherever such notification does not already obtain. (2) To make systematic provision for the diagnosis and treatment of all cases of syphilis not otherwise provided for.

B.—By the Section of Tropical Medicine and Hygiene (XXI.):—

"(*a*) The Section is of opinion that beri-beri among natives who live principally on rice is brought about by the continuous and too exclusive use of rice submitted to a too complete milling, which removes the cortical and sub-cortical layers of the grain. (*b*) The Section urges all authorities charged with the health of native communities to restrain by every means in their power the use of this rice in the dietary of coolies. (*c*) In view of the proved non-infectiousness of beri-beri, the Section suggests that all port and sanitary authorities should abolish foreign quarantine and other restrictive measures against this disease. (*d*) The Section resolves that the malady known hitherto under the name of Malta fever shall in future be named 'undulant fever.'"

C.—"That this Congress records its conviction that experiments on living animals have proved of the utmost service to medicine in the past, and are indispensable to its future progress. That, accordingly, while strongly deprecating the infliction of unnecessary pain, it is of opinion alike in the interests of man and of animals that it is not desirable to restrict competent persons in the performance of such experiments."

All these resolutions will be considered by the Permanent Commission.

The Permanent Commission proposed the following resolution to the Congress:—

"The Permanent Commission, considering that the hospitality of its English colleagues has surpassed all expectations, and considering that this gigantic Congress has been admirably prepared and organised, expresses its sincere and profound gratitude to the Committee of Congress and in their persons to the whole medical profession of England."—Report of Permanent Commission. (Signed) H. BURGER, Gen. Sec.

The President then proposed a vote of thanks from the Congress to the Government of H.M. the Queen of Holland for their generosity in defraying the expenses of the Permanent Commission of the International Congress of Medicine.

The delegates next bade farewell to the President of Congress, and Sir Thomas Barlow bade farewell to the Congress and closed the meeting.

THE MEDICAL MUSEUM.

Two spacious rooms in the Imperial College of Science, South Kensington, are occupied with what was, probably, the finest collection of pathological and medical exhibits ever shown at a medical gathering. The greatest credit is due to the unceasing labours of Mr. H. W. Armit, who, as Hon. Secretary of the Museum Committee, not only prepared a complete catalogue of some 500 pages in English, French and German, but, in conjunction with the International Association of Medical Museums, he organised a special section dealing with the various modern methods of preserving and exhibiting specimens. In this special department, Dr. Maude E. Abbott, Secretary of the International Association of Museums, acted as collaborator. Here were illustrated various methods of preserving morbid specimens after the Kaiserling method, of rendering organs and tissues transparent for demonstration purposes. Perhaps the most striking exhibit was that by Professor B. Wahby, of Cairo, whose method of injecting fusible alloy into blood-vessels to show the branchings excited great interest. Space will not permit of a detailed description of all the exhibits in the other sections, but special mention may be made of that showing the effects of dust in producing diseases of the lungs, arranged by Dr. E. Collis, of the Home Office, London (Section XVIII.). In Section XXI. were exhibits showing polyneuritis in beri-beri, produced experimentally by defective feeding, by Drs. H. Schaumann (Hamburg) and Casimir Funk (London). Mr. J. E. R. McDonagh showed photographs and microscopic slides illustrating the different stages in the development of the leucocytozoon syphilidis. The wax models and photographs of true and false hermaphroditism shown by Dr. Magnus Hirschfeld (Berlin) formed an interesting collection. From the Bureau of Plant Pathology, U.S.A., was an important exhibit of plant cancer.

International Gathering at Bath.

Special mention must be made of the excursion to the famous city and bathing establishment of Bath on August 13th, when a large party of members and their wives enjoyed the hospitality of the Mayor and Corporation. An examination of the historical Roman baths, a visit to the renowned Pump Room, and a tour of the chief places of interest in motor-cars, enabled the visitors to form some idea of the glories of this ancient health-resort. The guests were entertained to lunch in the banqueting-room of the Guildhall. Dr. Robert Abbe, of New York, proposed the toast of "The Hot Mineral Springs of Bath," to which Lord Alexander Thynne replied.

The Medical Exhibition

was unique in the extent of its organisation and the attractiveness of its exhibits. There were no less than 187 stands at which were shown every conceivable requisite for use in medicine, surgery and nursing. Space forbids our enumeration, but we may mention some of the most important in the various sections.

Foods and Beverages.

The Apollinaris Company were well in evidence with an exhibit in which that most useful and popular natural aperient water, Apenta, occupied a prominent position. Nothing need be said as to the attractions of Apollinaris water. The notice of medical men, however, may be particularly drawn to the large stone bottles in which this famous water is now supplied for table use. The cork is easily drawn from these bottles, and the water is clear, cool and sparkling. Patent stoppers are supplied by the company, and there is no doubt that by the use of these large stone bottles great economy can be effected. The firm, moreover, offer special terms to the medical profession, who can thus obtain this fine table water at a cost that compares favourably with ordinary syphon soda water.

The Angier Chemical Co. were showing their well-known emulsion and also some very effective throat and cough tablets. An attractive exhibit was that of the Horlick's Malted Milk Co., whose ideal food drink and malted milk lunch tablets afford a striking example of modern scientific methods as applied to the preparation of easily assimilable nutriment. Numerous specimens of natural mineral waters were exhibited by Messrs. Ingram and Royle, Ltd., notably those of Carlsbad, Chatel Guyon, Contrexéville, Hunyadi Janos, and Vichy "Celestins." Messrs. Keen, Robinson and Co., Ltd., were showing their famous preparations of barley, groats, as well as Colman's mustard and sinapisms. Lemco and Oxo were well to the front with their invaluable concentrated preparations of beef. The Maltine Manufacturing Co. exhibited their well-known "Maltine," plain, or in combination with cod liver oil, pepsin, or cascara. At the stall of Mellin's Dietetic Preparations were to be seen "Lacto," a dry powder consisting of pure fresh cow's milk and Mellin's Food, and Mellin's Food biscuit and chocolate. A fine assortment of milks and chocolate were on view at the stand of the Nestlé and Anglo-Swiss Condensed Milk Co. Next to this was the exhibit of St. Ivel, Ltd., who were showing their renowned lactic cheeses, also a concentrated food consisting of pure milk caseinogen, with lecithin and glycerophosphate of soda, known as "Visem." Diabetics were well catered for by Messrs. G. Van Abbott and Sons and also by Messrs. Collard and Co. Numerous peptonised milk preparations were on view at the stall of Messrs. Savory and Moore, Ltd., as well as their well-known food. Virol was also much *en évidence.* The valuable preparations of "Bovril," Ltd., formed an attractive exhibit, while the well-known essences of Messrs. Brand and Co. were shown side by side with "Ferrocarnis," an iron tonic food, as well as "Fever Food," for use in the tropics.

Drugs and Appliances.

The Denver Chemical Manufacturing Co. made a direct appeal to the visitors with their well-known "Antiphlogistine." The Chas. S. Phillips Chemical Co. showed their well-known drugs. First and chief was the Phillips Milk of Magnesia, which has always seemed to the writer one of the most perfect of pharmaceutical preparations. Practically tasteless, each fluid ounce contains some 24 grains of magnesium hydrate. For children, it is a most valuable and convenient form of administration of what is probably one of the most widely used remedies in the pharmacopœia. Another excellent product is the Phillips compound phospho-muriate of quinine, which is put up in elixir and in powder form. The formula is printed on the label.

Messrs. the G. W. Carnrick Co. were represented in their usual comprehensive manner. It would be impossible to mention in detail their numerous preparations. A word, however, may be given about trypsogen, which is claimed to contain the internal secretion of the glands of Langerhans, and thus to supply the deficiency met with in diabetes mellitus. It has, at any rate, been shown that the internal secretion of the pancreas plays an important *rôle* in the metabolism of the carbohydrates. Another scientific preparation of this firm in secretogen, which contains the hormone, secretin, which was shown by Bayliss and Starling to act as the physiological stimulus to the outpouring of the digestive enzymes. It is more rational thus to stimulate with secretin than to supply artificial digestive ferments. Secretogen is sold in tablet and in elixir form.

Messrs. Armour and Co. made a good show with their well-known digestive ferments and other preparations. A specially elegant remedy is their elixir of enzymes. It is most palatable, and its possibilities in bringing relief to dyspeptics may be gauged from the fact that a single tea-spoonful is sufficient to peptonise 1,000 grains of albumen. Their pituitary liquid is obtained from the pituitary body of the ox. It is a clear, colourless solution, put up in one cubic centimeter ampoules for intra-muscular injection. The junket powders of the same firm may be specially commended for use in hospitals. Being in the form of a dry powder it keeps sweet indefinitely. Vigoral is an essence of beef worthy of notice by all who have to cater for invalids. It is also sold in cubes for the convenient making of bouillon.

The Bayer Company showed an extensive collection of their many well-known drugs, which have in some cases become household words in medicine, such as phenacetine, sulfonal, trional, aspirin, protargol, mesotan, and tannigen. An interesting new preparation is cycloform, which acts as a superficial antiseptic and anæsthetic. It can be used as a powder or as an ointment. In the latter form it contains 10 per cent. cycloform and white hazel, and is specially recommended in the treatment of hæmorrhoids and pruritus. Jothion was also shown. There is little need to remind medical readers of the convenience of a non-staining preparation which contains no less than 80 per cent. of iodine in organic combination. It is put up as ointment in original tubes containing 10 per cent. of jothion, and in this form will be found useful wherever iodine treatment is necessary.

A magnificent show was provided by Messrs. Burroughs Wellcome and Co., who commanded the attention of visitors upon arrival. In addition to a fine exhibit of pharmaceutical preparations, first aid appliances and medical equipments, were to be seen the firm's hypodermic and other syringes, dressings, standardised vaccines, sera and tuberculins, as well as a unique collection of medicinal plants from their materia medica farm at Dartford. Messrs. Thos. Christy and Co. showed numerous chemical products of use in medicine, such as glyco-heroin, glyco-thymoline, lysoform, ergoapiol, among other known and trusted preparations. At the stall of Messrs. Fairchild Bros. and Foster were to be seen "Panopepton," and a valuable wheat and milk food known as "Laibose." Among the many interesting exhibits shown by the Hoffmann-la Roche Chemical Works, Ltd., were omnopon, thiocol and thigenol, the latter being a valuable organic sulphur compound. No less than fifteen preparations of cyllin were shown by Jeyes' Sanitary Compounds Co., Ltd. The various preparations of glidine, a pure, concentrated food made from wheat, with lecithin, iodine, and bromide, as well as iodex, a non-staining iodine, were shown by Messrs. Menley and James, Ltd. A large number of bacterial vaccines and sera were exhibited by the H. K. Mulford Co. The new therapeutic agents known as "Phylacogens," based upon the theory of multiple infections, were prominent at the stall of Messrs. Parke, Davis and Co. Among the pharmaceutical preparations shown by the J. D. Riedel Co. were "Aperitol," a compound of phenolphthalein with the sedative principle of valerian, "Mergal," an organic mercurial salt for use in syphilis, and "Gonosan," a valuable remedy in gonorrhoea. "G.B." diabetes whisky, "Junora," the "wine of health," and "Lecithin-Ovo," were the main exhibits at the stall of Messrs. Humphrey Taylor and Co.

It may be added that Messrs. Burroughs, Wellcome and Co. have secured unique distinction in connection with their exhibit at the International Congress of Medicine. In two of the sections the highest possible award has been conferred upon them by the international jury for their pharmaceutical preparations, fine chemicals, and antiseptics in section 2, and in section 5 for serum therapy, organo-therapy, and bacteriology.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Aug. 16th, 1913.

CIRRHOSIS OF THE LIVER.

THE medical treatment of alcoholic cirrhosis of the liver should be, says Dr. Fiessinger, that of stimulating hepatic neo-formation. From modern anatomical researches it has been shown that a cirrhotic liver endeavours to compensate the functional troubles produced by sclerosis by multiplying its parenchymatous cells; the compensation is thus effected under the form of cellular hyperplasia. The clinician should consequently seek to stimulate this reaction by acting directly or indirectly on the hepatic activity. The first thing to be done is to diminish or restrain the progress of intoxication by an appropriate *régime.* Certain authors recommend the use of intestinal antiseptics (naphthol, salol, benzonaphthol, etc.), but clinical facts have shown that this treatment is illusory, the absorption of antiseptics possessing, as proved by Dr. Robin, an antiseptic effect and this accentuates digestive fermentation, hence intoxication. Consequently no chemical antiseptics should be prescribed; they may be replaced by lactic ferments.

As hepatic stimulants, Dr. Robin classes them as follows:—

Stimulants of the mineral series.
Stimulants of the vegetable series.
Stimulants of the animal series.

Of the first named, bicarbonate of soda in small doses, half a drachm to a drachm daily, is a good stimulant of the biliary secretion. It should be prescribed in solution and taken half-an-hour before meals and two hours after. Phosphate of soda is a weak cholagogue; it is prescribed in the same doses as the bicarbonate. Benzoate of soda is much employed for the accumulation of uric acid; it is also diuretic and an hepatic stimulant. It is prescribed in 10 or 20 grain doses three times a day. Sulphate of soda is also a cholagogue and a diuretic in small doses and laxative over two drachms. It can be prescribed with bicarbonate of soda—

Bicarbonate of soda, 1 oz.
Sulphate of soda, 1 oz.,

a teaspoonful in a tumbler of tepid water every morning.

Dr. Robin combines all the above in one formula:—

Bicarbonate of soda, 2 drs.
Phosphate of soda, 1 dr.
Sulphate of soda, 1 dr.
Benzoate of soda, 40 grs.
Iodide of potassium, 20 grs.

For one packet, dissolve in a quart of boiled water. Three ounces in the morning and renewed half an hour before each meal (2) and two hours after dinner. The solution is warmed and drunk slowly. A large glass of Vichy water (Célestins) with a teaspoonful of Carlsbad-Sprudel salts (bicarbonate of soda, sulphate of soda, chloride of sodium) may be substituted, or Rochelle salts, one or two drachms taken fasting in a glass of warm water.

To the foregoing treatment Dr. Castaigne adds a ferruginous treatment. Iron seems to stimulate the hepatic cell, to improve the general condition and diminish hepatic insufficiency. All these drugs are necessary, but might be employed alternately, each covering a period of 10 days. For instance,

Robin's formula, 10 days.
Carlsbad salt, 10 days.
Rest or Rochelle salt, 10 days.

Stimulants of the vegetable series comprise: Boldo leaves (40 grains infused in a cup of water sweetened with a teaspoonful of glycerine, taken at bedtime); boldine (four pills during the day); jaborandi (five grains in infusion three times a day); drastis, as Cape aloes, podophyllin, euonymine, etc., associated with ext. of belladonna to diminish painful contractions. Stimulants of the animal series include glycerine (two tablespoonfuls at night in an infusion of boldo), ox gall, powdered liver (a teaspoonful at the beginning of each meal) (2).

Such are the different agents at the disposal of the clinician for the treatment of cirrhosis of the liver. Their use may be alternated, associated, or combined to obtain a better effect, but success is not always certain. Frequent are the cases where progressive evolution towards hepatic insufficiency is beyond the control of therapeutics, especially in cases of atrophic cirrhosis, much less amenable than the hypertrophic form.

GERMANY.

Berlin, Aug. 16th, 1913.

AT the Society for Surgery Hr. Körte reported three cases of

OPERATION FOR ACUTE PANCREATITIS.

Certain points were common to the whole of the three: they were all of middle age, and were not especially fat. Two of the patients were women. The attacks came on suddenly without any warning. There was collapse, with excessive irritation in the abdominal cavity, which gave rise to the suspicion of ileus. In two of the cases a diagnosis could be made at the onset, as the pain first appeared in the epigastrium. The third case was looked upon as one of appendicitis; but on opening the abdomen exudation and necrosis of tissue made their appearance. In all the cases the exudation was hæmorrhagic. In order to get at the pancreas the gastro-colic ligament was divided, the capsule opened by a blunt instrument. In no case was any abscess found. As regarded the gall bladder the result was negative; there was no implication on its part, although in one case it had been stated that the symptoms had implied such an implication. A drain was inserted that reached to the pancreas. The pain ceased. The secretion discharged was at first serous, later purulent. Small particles of pancreatic tissue were cast off. In one case a pancreatic fistula remained open for a long time notwithstanding the administration of soda. In both the other cases the fistulæ closed readily.

The speaker considered that early operation was called for in all cases in order to prevent spread of the necrosis.

Hr. Bier spoke on the

ULTIMATE RESULTS OF TOTAL EXTIRPATION OF TONGUE.

He showed a man, æt. 36, on whom V. Bergmann operated for carcinoma of the tongue in 1901. In April, 1910, a recurrence occurred, for which another portion of the tongue was removed, leaving only a small stump. The floor of the mouth down to the cutaneous tissues was cleared out. In August, 1910, with return of the disease, another portion was removed, and on December 15th of the same year still another portion. The patient was now free from disease. The speaker remembered a case of

Esmarch's who was operated on 15 times for recurrence of cancer. After all this the man still lived 15 years. The speaker reported two other cases of unilateral extirpation with a permanent good result, and recommended that recurrences should be removed in every case. Permanent cures might be obtained even without the application of the Röntgen rays.

Hr. Borchardt mentioned a case of melanosarcoma that had been operated on six or seven times for recurrence, and which was now free from disease. At the Medical Society of Kiel, Hr. Langes related his experiences in the

Treatment of Myomata and Uterine Disorders by Rontgen Rays.

Beginning with a filter of aluminium, he soon went on to four, then went back to three, and treated each part by dividing the field into three. The parts thus treated were the abdomen, the sacrum, the parts adjoining, and, according to the severity of the case, the vagina, through lead speculums, and the perineum. In order to test the action through the sacrum and the ischiatic foramina, a pencil of pitch pine wrapped in an indiarubber finger-stall was inserted into the cavity of the uterus. The pencil was blackened equally whether the rays were passed through the anterior abdomnial wall or through the sacrum. The instrumentarium consisted in a rotax interrupter, Burger tubes with a 2mm. loading and 6 B.W. dosage, and an arrangement whereby the dose, which was mostly 20 pro field, could be varied at pleasure. No serious mischief was set up, at most some pigmentation of the skin. Of the fifteen cases of myoma that were accurately followed, 8 became amenorrhœic and 6 oligomenorrhœic, 14 showed distinct signs of reduction in size, the fifteenth case was a failure, due to faulty *technique*. Of 39 cases of uterine disease 24 became amenorrhœic, 9 oligomenorrhœic, 6 remained unchanged; in one the hæmorrhage was worse, so that total vaginal extirpation of the uterus had to be performed. All the cases of failure were treated in the early period of faulty *technique*. With the treatment as at present carried out there had been no failures. Success was generally obtained after two or three applications. Hr. Stoeckel was of opinion that moderate doses were the best; small ones did no good, and large ones sometimes did permanent mischief In the cases of myomata in young women he would always operate; application of X-rays amounted practically to castration, and objectionable symptoms that accompanied the menopause might be troublesome. We did not know which cell elements of the ovary were responsible for the internal secretion. He then spoke on the

Results of the Treatment of Inoperable Carcinoma,

which had been reported as brilliant. They had been so striking that the hopes of the profession had been revivified. It was unfortunate that mesothorium had now attained such a "pocket value" that it was nearly all snapped up by one or two institutions, so that most could only look on and watch how it succeeded in the hands of others; the individual having no chance of testing it himself.

CONTINENTAL HEALTH RESORTS.

Aix-la-Chapelle (Aachen).

Aix-la-Chapelle, as all Europe must know, is a climatic station of world-wide renown, beautifully situated on the west frontier of Germany near Holland and Belgium, and is the principal station on the railway from Cologne to Brussels, Paris, and London, as well as from Berlin via Dusseldorf to Belgium and France. It is also a stopping place for all express and corridor trains (trains de luxe) and a starting point for the trains running to Holland (via Maestricht), the Eifel and several branch lines. The soil on which this interesting city is built is for the most part composed of porous sand ("Aachen sand"), so that after heavy downpours of rain the streets and pathways are quite dry again in a very short time. A chain of beautiful hills (Aachen Woods) surround the entire valley in which this historic and health-restoring city lies. It is truly picturesque on all sides, a most pleasant and salubrious resort. Here are excellent hostels to suit all tastes and purses, English-speaking physicians of high medical renown, and baths unique in Europe. All the baths have comfortable hotels attached to them, so the visitors who live at the bath-houses can retire at once from their baths to their rooms (by lifts) without leaving the bath-house, and without exposing themselves to the risks of taking chills by crossing streets. Visitors can arrange to stay at most of the bath-houses "en pension," or otherwise, at very moderate prices. Those who are suffering from rheumatism, gout, paralysis, atrophy of the muscles, stiffness of the joints, skin diseases (particularly eczema), torpid affections of the liver, spleen, and any stomachic complaints, will find the Aix-la-Chapelle treatment (especially the douche) most efficacious, and in most cases a specific cure.

The Aix-la-Chapelle treatment combines usually drinking of the waters with the use of baths; as the plain bath, the douche and the vapour baths These baths are placed on the ground, through which the hot spring water runs. Consequently, however prolonged the bath treatment may be, no part of the bath-room can possibly become cool. The douche treatment here is especially effective and superior to any other on the Continent.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

GLASGOW.

Russian Delegates in Glasgow.

Following on the close of the International Congress of Medicine in London, the Russian delegates paid a visit to Glasgow, their aim being to visit the principal hospitals for the treatment of mental diseases. Included in the party were a number of lady physicians, and practically all the members are engaged in their own country in the special department of nervous and mental disorders. They were met at St. Enoch's Station by Dr. John Carswell, who escorted them to their quarters at the Grand Hotel. The series of visits were arranged to convey the delegates to the Royal Infirmary, the Eastern District Hospital which is under the supervision of Dr. Carswell, the new epileptic colony at Chryston, and Woodilee Asylum, including a luncheon given by the Corporation in the City Chambers. The second day's expedition consisted in a sail down the River Clyde from the Broomielaw, afterwards visiting Hawkhead Asylum, where they were entertained to luncheon. The following day a visit was made to Gartnavel Asylum and the university, after which the delegates proceeded to Edinburgh.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

A DOCTOR'S WIFE ON DRESS.

To the Editor of The Medical Press and Circular.

Sir,—"The regeneration of society is in the power of the woman, and she turns away from it. All future English generations might call her blessed, and she prefers to be called fashionable."—Stopford Brook.

I have been much interested in the correspondence on dress which has lately been published both in the *Times* and the Medical Press, but as one who has lived through many fashions from croquet and crinoline to tennis and tight skirts, I do not quite take the pessimistic view of the present style of dress set forth by some of the writers in both papers.

Personally I think that—ugly and immodest as the present fashion is when carried to extremes—it is no more a sign of the decadence of our race than was the crinoline of the 'sixties or the bustle of the 'eighties.

It has no deeper meaning than that the dressmakers set the fashion and those women who have no natural artistic taste blindly follow their lead. The tight skirt has held its sway a long while, probably because the dressmakers find it profitable owing to the very small amount of material it contains, but presently it will disappear and we shall perhaps return to the full skirt of early Victorian days.

From the hygienic point of view, however, the present style of dress seems entirely wrong, from the open neck devoid of any covering even with an outdoor coat to the gossamer silk stocking which is worn out of doors even in the coldest weather. The underclothing, also, is of the scantiest. Often the skirt is so tight that no petticoat of any sort is possible. Worst of all is the corset which compresses the hips and abdomen in order to give a tall and slim appearance to the figure, and is cut so long below the waist that it must hamper all free movement of the lower part of the body. A short time ago a saleswoman in the corset department of one of the large London drapers was heard to say to a customer regarding a particular kind of corset: "Of course, madam, these corsets are not for sitting down in."

It hardly seems possible that in these days when hygiene is taught to almost every child in the elementary schools there should still be women of the educated class foolish enough to wear corsets so long and tight that they are doomed to remain standing all the time they wear them. These corsets have one redeeming feature, however, for they do not, as a rule, compress the waist, and the upper part of the body is left quite free.

But on the whole even women's dress is not quite so senseless as it was in my young days, and children's clothing has altered entirely for the good except among the poorer class. In women's underclothing, some advance has been made, and the comfortable and hygienic combination garment introduced about thirty years ago has surely come to stay. So, too, let us hope, has that most useful of all feminine costumes, the coat and skirt, with its accompanying neat skirt or elegant blouse. I cannot think that this costume can ever go the way of other fashions. It seems essentially suited to the Englishwoman and is worn by, and looks well on, the wealthiest woman of fashion or the little maidservant on her weekly outing. It changes with the fashion as to length of coat and width of skirt, but never entirely disappears.

But the greatest reform has been in the clothing of our children. I still remember the miseries of the winters of my childhood, with frocks cut low in the neck and short in the sleeve, no woollen underclothing, or only the shortest of vests, with only white cotton stockings, calico drawers, and one or two loose, bulky petticoats to cover the lower part of the body. Added to these the all-essential crinoline, worn then by quite young children, which kept away from the body half the warmth the skirts might have given.

I quite envy the children of the present day with their warm combinations and knickers, their short skirts and blouses, or the still more modern and simple "djibbah." Unfortunately the children of the poor are not yet thus comfortably clothed and for the most part still wear the old-fashioned bulky garments. I feel that much might be done if only the "Schools for Mothers," heads of mother's meetings, etc., would take up this question of dress and teach the women how to make the better fashioned garments worn by our own children.

I agree with Stopford Brook that the regeneration of society is in the hands of the woman, and am hopeful enough to believe that she is no longer turning away from it, but that the future generations will indeed call her blessed, even though she still likes to be fashionable.

DOCTOR'S WIFE NO. 3.

August 16th.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—I have been vastly amused at the three letters on dress that have appeared in your last two issues. Your correspondents agree in disparaging the present fashion, but not one of them seems to know what she objects to. "A Doctor's Wife" complains that Englishwomen's dress to-day is "anti-hygienic, immodest, and indecent." It seems to me that the first epithet could be applied with greater propriety to any kind of women's clothes since the ancient Egyptians than to what we wear to-day. Only since the blessed advent of the short skirt can we stir outside the house without trailing clouds of dusty glory in our wake. As to the vague charges of indecency and immodesty, it is hard to know what "A Doctor's Wife" wants. She praises Frenchwomen for knowing "how to enhance what charms they may possess, how to veil defects of face or figure." I fail to understand on what grounds we are called indecent, unless it is for displaying our charms, a trait which, in our French sisters, is held up for our applause and imitation. "A Consultant's Wife" makes out no better case. She says the French tendency has always been the same, "the crinoline, the bustle, the pannier and no end of different forms of corsets to distort the form . . . and now we have the semi-nude." Does "Consultant's Wife" wish us to look as God made us, or not? She first complains of our figure being concealed and then of its being exposed, and apparently does not like either. What does she want? She really must make up her mind. It is hard to answer such contradictory objections, but I hope, sir, you will spare me space for my plea on behalf of clothes as they are. I am not a Victorian lady, but a woman of to-day. I play golf and go for long rides on my bicycle, and I appreciate our modern frocks. They are comfortable and clean. I no longer have to practise a sightly way of bunching up superfluous yards of stuff when I am out on a muddy afternoon, and putting my foot through tail braid is a thing of the past. Besides, a skirt that used to take four to six yards of material to make now only uses 2¼, and that allows a width of 1¾ yards, which is quite enough for freedom, and saves some extra shillings. As for modesty: After all, we are bipeds, and most people know it, so why should we try to copy the cylindrical uniformity of Mrs. Noah? And if we may show our necks in the evening, why must they always be hidden from the light of the sun? And surely no one wants us to go back to the steel corsets of our mothers. There is no immodesty in looking like a human being. Our dress to-day may show the soft lines of life, but they are better than the coarse curves of the *corsetière*. I apologise for trespassing so long on your valuable space, and, since it seems to be the fashion, but disclaiming all polygamous suggestion, beg to sign myself

DOCTOR'S WIFE NO. 4.

Dublin, August 14th.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to the correspondence on woman's dress, may I offer a suggestion which, if adopted, would settle the question once for all? There should be a regulation costume for women, with heavy penalties inflicted for any variation from the standard. This should be a combination suit—something like those worn by mechanics—made of a strong canvas in a drab, khaki, or other serviceable colour. The garments worn beneath this would be left to the taste of the wearer, so leaving scope for individuality. A short law to this effect would do more towards promoting Christian principles than much of the more pretentious legislation of to-day. One point further. I should like to emphasise. The garment must not button up at the back.—I am, etc.,

GYNÆCOLOGIST.

Liverpool, August 16th, 1913.

OBITUARY.

DR. F. M. MILLER.

WE regret to record the death of Dr. Frederick Montague Miller, J.P., M.R.C.S., L.R.C.P.Lond., L.S.A., which took place on the 15th inst., at his residence, "Elstead," Arden Road, Finchley, after a long illness, in his 66th year. The deceased, who qualified in 1864, was educated at the Merchant

Taylors' School and St. Thomas's Hospital. Settling in Amhurst Road, Stoke Newington, he soon built up a large and lucrative practice, ultimately moving to Clapton. For many years he enjoyed the confidence of a large number of patients, and at one time he was probably one of the best known practitioners in North London. By many he will be remembered on acount of his bedside manner, which was dogmatic and decisive to a degree, while by others his memory will be cherished as a preacher, for at one period of his life he exercised the dual calling of a minister and practitioner of medicine. In 1902 he was elected Mayor of Hackney, when he was in the zenith of his popularity, being re-elected to that office in 1906. He was Chairman of the Libraries Committee when Mr. Carnegie made a grant to the borough, when Princess Christian laid the foundation-stone of the Central Public Library, and when the King and Queen, then Prince and Princess of Wales, formally opened the building. He was passionately fond of horses, and his dashing turn-out was always regarded with something of envy by those qualified to judge. When, owing to failing health, he retired from active practice a few years ago, it was felt that a notable figure in the medical, municipal and social life of Clapton and Hackney had been removed. Latterly he had been confined to the house, and the end came at 4.30 on Friday afternoon last. Dr. Miller leaves a widow and two daughters to mourn his loss. To his bereaved family we beg to offer our respectful and sincere sympathy.

SPECIAL ARTICLE.

LEPROSY IN SOUTH AFRICA.

The South African Medical Record for May 24th and June 14th, 1913, is devoted to the subject of "Leprosy in South Africa." The first issue contains a paper of great interest by Dr. Robert Morrow on the history of the disease in South Africa up to the establishment of the first leper asylum, Hemel en Aarde. He discusses the subject in two periods—one prior to the arrival of the white man, and one subsequent thereto. The first mention of leprosy in South Africa is in the year 1756, but there are abundant signs that the disease itself has existed there from time immemorial, and that it cannot be regarded as a relatively recent importation. The author considers the commercial relations of South Africa in the past, and concludes that leprosy has existed along the east coast for centuries, that Mashonaland was a leprous country in the time of the gold-hunters, and that the disease was not less prevalent in the Great Zimbabwe than it is in any modern Asiatic city of equally large population.

Dr. Morrow shows that a study of the various Bantu tribes, together with facts bearing on leprosy in these tribes, indicates that the disease could not be visible to Europeans entering the Bantu territories for the first time, and that it existed in most of these tribes prior to the European entrance; also, in almost all tribes a recrudescence of leprosy followed in the track of the new civilisation, owing to the life of the leper being protected by the introduction of Christian teaching and European laws. In 1817 the leper asylum at Hemel en Aarde was established, and some temporary lazarettos erected in which lepers could be confined until they could be forwarded to the asylum.

The next paper in the journal deals with the administrative side of the leprosy question. The author, Dr. C. F. K. Murray, Official Visitor, Robben Island, discusses the subject at length, and suggests considerable modification in the present system of segregation. He advocates the establishment of leper settlements to admit of family life; the establishment of one or more central hospitals to which all the worst cases should be sent for treatment; and the modification of all existing establishments on this basis. With regard to Robben Island he advises the adoption of one of three courses: to remove the lepers to the mainland, or to remove the lunatics and convicts, leaving the island as a leper settlement, or to abandon the island as an official establishment altogether. A lengthy report by Dr. Bayon, research bacteriologist in leprosy, is appended. It deals with the advisability of segregation, with the prevention and cure of the disease, and with the suitability of Robben Island as a place of detention. The journal of June 14th is devoted to a paper of great value by Dr. Bayon on the recent experimental leprosy research. The author deals very fully with the attempts to cultivate the micro-organism of leprosy; he concludes that Kedrowsky's culture is one of true leprosy, capable of producing leprous lesions in animals, and reacting in a specific fashion with leper's serum. He states that the most suitable animals for inoculation are the rabbit, the rat and the mouse, and that the resulting lesions are similar to those caused by certain strains of human tubercle. According to Stanziale's and Serra's experiments the Wassermann reaction is positive in rabbits which have been successfully inoculated. With regard to the contagiousness of leprosy, the author believes that it is relatively easily communicable from the diseased to the healthy under unhygienic conditions by intimate personal contact. When, however, hygiene is good and contact not intimate one case in a thousand or even less may get infected. Dr. Bayon's paper is illustrated by many very beautiful coloured microphotographs of the bacilli of leprosy both in culture and in the tissues.

REVIEWS OF BOOKS.

DISEASES OF THE LIVER. (*a*)

This book puts within the reach of its readers a lucid, well-authenticated, and interesting account of the factors of liver disease, and its historical character is vouched for by its evident dependence upon many original sources and prime authorities, although this is not pushed to the exclusion of diverse views, and an excellent compendium of reference to other works appears on nearly every page. A chapter taken as an illustration of the merits of the book, and which is most likely to be met with by every member of the profession is the article on cirrhosis of the liver, in which the author commences by giving a list of the various ways in which this disease has been classified, and finally prefers to divide the disease into one of two kinds—viz., the ordinary, portal or common cirrhosis, and that of biliary cirrhosis. This is followed by an historical review, the ætiology of the condition, and, later, its pathology and morbid anatomy. The clinical part of the disease needs special mention, and the treatment is all that could be desired. Dr. Rolleston goes into detail when necessary and works on a broad canvas, dealing not only with events and facts, but also with questions of numbers and statistics of the physician in his widely scattered medical fields. The book has all the merits desiderated in a work of its kind, including clearness of arrangement, accuracy of statements, and facility of reference, and the coloured plates, photomicrographs and figures are well produced. It is a well-written and interesting work on a fascinating subject.

DISEASES OF CHILDREN. (*b*)

From year to year the field of knowledge of the diseases of children is widening, and along certain lines considerable advances are continually being made, so that in this, as in other subjects, it becomes a matter of increasing difficulty for an individual to cope with the mass of new material and to formulate accurate conceptions of the value of the results of recent researches. The reader needs not only a comprehensive and authoritative text-book which he can study, but also a book of ready reference in which the rarer varieties of disease receive adequate notice. In the present volume every endeavour has been made that the work shall be concise and of practical value

---

(*a*) "Diseases of the Liver, Gall-Bladder and Bile Ducts." By Humphry Davy Rolleston, M.D. Second Edition. London: Macmillan and Co., Ltd. 1913.

(*b*) "Diseases of Children." By various Authors. Edited by Archibald E. Garrod, D.M., M.A., F.R.C.P., F.R.S., Frederick E. Batten, M.D., M.A., F.R.C.P., and Hugh Thursfield, D.M., M.A., F.R.C.P. Fully illustrated. Pp. 1,184, with Index. London: Edward Arnold. 1913. Price 30s. net.

to the physician, special attention being devoted to the pathology, symptomatology, prognosis and treatment of each disease. It is therefore with the greatest pleasure that we welcome the publication of this important work by various authors. The names of the editor are sufficient guarantee of the thoroughness with which the volume has been produced, and they have been fortunate in securing the collaboration of many well-known and recognised authorities on various special branches of children's diseases. On this account the value of the work is considerably enhanced, and this wealth of special knowledge has been set forth with a completeness which the editors believe has not hitherto been attempted in this country. With this claim we feel that those who have a large experience of pædiatric literature will be disposed to agree. In a large volume of this kind there are naturally many points which are open to discussion and possibly to criticism, but where all the subject matter is of such a high standard and bears unmistakable evidences of careful and judicious selection it would be uncalled for to take exception to particular passages. While avoiding prolonged discussion of controversial and disputed problems, the editors have sought to obtain authoritative statements of various questions in dispute with a judicial summing-up of the arguments, such as would at once put the reader in possession of the known facts, and be of practical help to him. The contents are divided into four prolegomena, followed by twenty-three chapters and an excellent index. Heredity and Immunity receive due notice at the hands respectively of Dr. Gossage and Dr. Thursfield. Dr. Garrod contributes three articles which are among the most interesting in the whole book on diseases of the ductless glands, disorders of metabolism, together with an introductory survey of disease as it affects children. Dr. Poynton's chapter on cardio-vascular disease is clear and concise, rheumatic heart disease being considered in detail, since this is the form most frequently met with. Diseases of the skin are dealt with in Dr. Adamson's contribution, which gives useful indications for diagnosis and treatment. Dr. Voelcker writes in interesting fashion of rheumatism and chorea, the latter of which he defines as "a rheumatic affection of the central nervous system," which view is in accordance with the opinions held by most of those who have worked at London hospitals. On a systematic survey of the whole treatise, we find that no essential feature of the diseases of infancy and childhood has been overlooked, and at the same time the attention of the reader is kept from wandering, and salient points in various conditions are further emphasised by an abundance of photographic reproductions of actual cases and of line diagrams and charts. Finally, from every point of view, we can assert with conviction that this work fills a hitherto-existing gap in our British literature of children's diseases, and is well worthy of a place on the library shelf of every medical reader who is in any way concerned with this subject.

IONIC MEDICATION. (*a*)

The subject of "ionic medication" is one which will, very probably, furnish the stimulus to a great deal of clinical research in the near future, and the inspiring text to many contributions to many of our medical journals. Our author defines this, his chosen subject of inquiry, as "a method of treatment in which electric currents are used for their power of setting the constituents of a saline solution in orderly motion in a definite direction." The idea of utilising the weird powers of electricity for the treatment of the physical ills of the human frame is (necessarily) an old one; the disappointing results obtained from all the venerable "simples" in turn, kept the suffering descendants of Adam always on the look-out for a panacea—the representative symbol in the physical world of the powers and gifts of a Messiah in the theological. Thus every notable discovery of an element, metallic or metalloid, solid, fluid or gaseous, was soon followed by experimental investigation of the effects of application of the same to the afflicted human organism. Disappointment has been the more frequent result; but we can well afford to encourage perseverance in investigation, having regard to the vastness of the reservoir of clinical and physical and physiological facts which has been gradually filled by the fruits of the laborious harvest. Our author gives a good account of the present position of the ion in the scientific field of vision; and his description of the clinical adaptation of its properties is readable and precise to a praiseworthy degree. As the subject is still in its relative infancy, the collected evidence is, necessarily, in large proportion secondhand. It is not, sooth to say, calculated to make us more confident or more hopeful than we were before—but such is the doom of the elderly examiner of the items for therapeutic confirmation, who has long and laboriously studied his subject. A good testing instance, we believe, is offered by the interesting item, lupus. And of it we learn: "This form of specific ulceration would naturally appear to be a very suitable condition for treatment by ions; and so it is, but it is by no means easy to obtain a permanently good result. This may be due in part to the peculiar fatty or waxy nature of the tubercle bacillus, which tends to render it a non-conductor of electricity." That wretched bacillus! Of course, we anticipated that the fault of incompletion would be laid at its door! And so it shall evermore be, till the practitioner begins to neglect the presence of the bacillus, and concentrate his attention on the personality of his patient and the defects of the same inherent or acquired.

NOTES ON THE TREATMENT OF TUBERCULOSIS (*a*)

In this little book the author urges the importance of lime salts in the treatment of tuberculosis, believing that Nature's method of cure in that disease is mainly the calcification of tubercle, combined with the development of fibrous tissue in abundance for the purpose of surrounding and thus cutting off the diseased from the healthy part. Dr. Laird gives the ingredients of a special mixture, the persistent use of which has yielded good results in his hands, containing the iodide and benzoate of sodium, arsenic, the tinctures of pulsatilla and baptisia, suitably flavoured. Reasoning from a large number of authorities quoted and all the facts stated, together with his own experience, the author concludes that tuberculosis is a preventable disease, and that the best means at our disposal for its prevention lies in our keeping up to full efficiency the calcium contents of the system in infancy, childhood and adolescence.

SYMPTOMS. (*b*)

We are not surprised that the popularity of Dr. Mackenzie's work has called for this second edition, and we are glad to think that he has increased the obligation under which he has placed the profession by the way he has responded. It is some time since we have read a more suggestive book, and suggestiveness is one of the most desirable qualities in any medical work. Whether the views put forward by the author prove to be correct or not time and patient research alone can tell, but whatever may be the outcome of this research there can be no doubt that the seekers will be benefited. We have been so long accustomed to associate pain directly with the diseased or injured viscera that it is difficult to divest our minds of the habitual idea that the pain is in the viscus, yet how often does this idea lead us astray. Dr. Mackenzie has opened for us a new field for investigation, a field, too, which is to be explored by the clinician, and for the exploration of which he does not require the costly armamenta of the scientific laboratory. We feel sure that clinicians will gladly seize the opportunity thus offered to them, and we can heartily recommend to them the excellent guide that Dr. Mackenzie has prepared.

MEDICAL NEWS & PASS LISTS.

The Highland and Islands Medical Service.

It is announced that the names of those who are to constitute the Board to administer the Highlands and Islands Medical Service Act are as follows:—Sir John Dewar, chairman; Sir Donald MacAlister, Principal of the University of Glasgow; Lady Susan Gilmour, honorary secretary of the Queen Victoria Jubilee Institute for Nurses; Dr. McVail, of the Scotish Insurance Commission; Dr. Leslie Mackenzie, of the Local Government Board; Dr. John Macpherson, of the Lunacy Board; Mr. J. L. Robertson, Chief Inspector under the Scotch Education Department.

The Sale of Patent Medicines.

The Select Committee appointed to consider and inquire into the question of the sale of patent and proprietary medicines, medical preparations and appliances, and advertisements relating thereto, report that "as it will not be in their power to make a full report in the present Session, they have agreed to recommend that a Committee on the same subject be appointed in the next Session of Parliament."

County Sanatoria for Tuberculosis.

The Kent County Council have decided to build a central sanatorium for Kent for the treatment of tuberculosis. Provision will be made for 100 beds, and the capital expenditure which will fall upon the council will amount to £6,000. The original proposal was to erect more than one building with provision for a total of 205 beds.

The Cornwall County Council decided last week to apply to the Local Government Board for power to borrow £3,000 for the purpose of providing a sanatorium for tuberculosis patients under the National Insurance Act. Mr. R. G. Rows, Chairman of the Finance Committee, explained that it was proposed to purchase the Watergate Bay Hotel, two and a half miles from Newquay, and convert it into a sanatorium. Assuming that the cost was £7,500, the Local Government Board would provide three-fifths, or £4,500, and the county two-fifths, or £3,000. The hotel would provide accommodation for 60 beds at least, and he believed it would be one of the finest establishments in England.

Extermination of the Common House Fly.

A vigorous campaign is being waged in America against the house fly, and enormous numbers of the winged pests are being destroyed daily. The Board of Health have circulated instructions telling the public how to "swat the fly," and public opinion is everywhere being aroused with the object of stimulating the work of extermination.

Educational work amongst children is being conducted, and in many schools cinematograph pictures are being shown of the fly's wanderings from the garbage heap where typhoid lurks to the family's roast joint on which he is shown wiping his feet realistically. Greater interest also is being taken in matters affecting public health, and people are beginning to realise the disease-breeding character of the domestic house fly, especially in the dissemination of infantile diarrhœa and other infectious diseases. A solution of Jeyes' Fluid is freely sprayed in dark corners, crevices, etc., where flies breed, the larvæ are destroyed before they develop into flies. All manure heaps are disinfected with the fluid, and sinks, drains, lavatories, etc., are cleansed every day with water containing this disinfectant.

Middlesex Hospital Medical School.

The following scholarships, prizes, and certificates have been awarded during the sessions 1912-1913 at the Middlesex Hospital Medical School:—

Lyell Medal and Scholarship, A. O. Gray; John Murray Medal and Scholarship, F. W. Browne; Hetley Clinical Prize, A. O. Gray; Leopold Hudson Prize, H. A. Lucas; New Zealand Scholarship, T. Julian; Second Year's Exhibition, D. W. J. Andrews.

Medicine—prize, F. E. Feilden. Surgery—prize, F. E. Feilden; certificate, T. C. Kidner. Practical Medicine—prize, F. E. Feilden; certificates, S. W. M. Jones, B. M. Mitra, and B. H. Singh. Practical Surgery—prize, C. P. Sells; certificates, B. M. Mitra and F. E. Feilden. Practical Midwifery—prize, O. C. Link. Pathology—prize, T. C. Kidner; certificate, B. H. Singh. Psychiatry—prize, H. C. Samuel; certificate, C. J. B. Way. Pharmacology—prize, E. H. Lake; certificate, F. C. Mason. Anatomy—prize, D. W. J. Andrews; certificates, V. H. Dye, H. De Morgan, D. C. Ogilvie, and W. L. Thomas. Physiology—prize, D. W. J. Andrews; certificate, D. C. Ogilvie. Practical Anatomy—prize, D. C. Ogilvie; certificates, J. Fox Russell and C. J. L. Wells. Histology—prize, E. H. Lake; certificates, F. C. Mason and W. B. Gabriel. Embryology—prize, W. T. Warwick; certificate, F. C. Mason. Practical Pharmacy—prize, L. G. Lunnon; certificates, H. C. Samuel and R. F. S. Mason. Biology—prize, G. Howorth; certificates, C. Shelton, L. G. Lunnon, and A. K. Ince Jones. Organic Chemistry—prize, F. C. Mason; certificates, E. H. Lake, A. Selby Green, and W. B. Gabriel. Inorganic Chemistry—prize, M. B. Tench; certificates, A. I. Cox and J. J. Chiappa. Physics—prize, A. I. Cox; certificates, M. B. Tench and A. G. Hewer.

Surgical Appointments at the London Temperance Hospital.

The rearrangement on the surgical side at the London Temperance Hospital has been made, and Mr. W. McAdam Eccles, M.S.Lond., F.R.C.S.Eng., Mr. H. J. Paterson, M.C.Cantab., F.R.C.S.Eng., and Mr. Arthur Evans, M.S.Lond., F.R.C.S.Eng., have been appointed surgeons, and Mr. James McClure, M.B., F.R.C.S., surgeon to out-patients.

NOTICES TO CORRESPONDENTS, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Contributors are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

Reprints.—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Dr. Leith Murray.—We have written to our French correspondent for the desired reference.

CHEAP SUMMER EXCURSIONS FOR MEDICAL MEN.

We are asked to announce that the last of the cheap summer excursions to the Health Resorts of the Continent, inaugurated this year by the Paris, Lyons and Mediterranean Railway, will leave London for Auvergne, Dauphiny, Savoy, Provence and Corsica, on August 30th, particulars of which can be had on application to the London office of the railway company.

Sportsman.—Doubtless, there is much to be said on your side of the subject, but it is hardly one to which we can open our columns.

CONTINUOUS NIGHT AND DAY SERVICE OF MEDICINE.

We are asked to announce that the West End depot of Messrs. Burroughs, Wellcome and Co. has been transferred from Messrs. Munro and Co., Regent Street, to Messrs. John Bell and Croyden, Ltd., 50 Wigmore Street, London, W. This depot will maintain a continuous day and night service and hold a complete stock, so that it will be possible to obtain supplies at any hour, even when Messrs. Burroughs, Wellcome and Co.'s warehouses are closed.

J. H. Selby should get the last edition of Drs. Castellani and Chalmers' "Manual of Tropical Medicine," which contains the latest researches on the subject of those eminent authorities.

Dr. T. J. Brooke-Kelly (Queensland).—Your paper on "The Surgical Treatment of Gastro-Intestinal Stasis" to hand, and is marked for early insertion.

THE TRANSACTIONS OF THE CONGRESS.

Each member of the Congress will receive a copy of the transactions of the Section to which he belonged, but it has been arranged to supply the complete set of the Congress transactions for a subscription price of £4. Applications should be addressed to the publishers, Messrs. Frowde, Hodder, and Stoughton, Oxford Press Warehouse, Falcon Square, London, E.C.

M.B.Oxon (London, N.).—It seems pretty well established that, in spite of all recent advances in synthetic chemistry, the only two drugs that possess a *specific* action in ophthalmic therapeutics are silver nitrate, a specific for the gonococcus, and zinc sulphate, which is specific for the Morax-Axenfeldt bacillus

Dr. W. B. (Beds).—The symptoms are very suggestive of ptomaine-poisoning, but it is necessary to use the utmost circumspection before attempting to incriminate the products of any particular tradesman.

THE NATHANIEL ALCOCK MEMORIAL FUND.

We understand that an appeal is being made to the friends of the late Professor Nathaniel Alcock to contribute to a fund for the benefit of his widow and four children. Owing to his untimely death and the moderate remuneration that generally falls to the lot of the scientific worker his family has been left wholly unprovided for. Contributions will be gratefully received and acknowledged by Professor E. H. Starling, Physiological Institute, University College, London, W.C.; or Professor A. D. Waller, Physiological Laboratory, London University, South Kensington, London, S.W. Cheques should be drawn to the order of Professor E. H. Starling or Professor A. D. Waller, and crossed "Alcock Memorial Fund."

P. W. R. (Brighton).—According to the views of Mr. E. M. Holmes, F.L.S., the myrrh of Scripture is not identical with that used in medicine, the former referring to perfumed myrrh, the product of *Commiphora erythraea*

F.R.C.S.Edin. (Berks).—It has only been recently reported that Prof. Townsend, of Lima, has discovered that verruga is transmitted by small blood-sucking midge of the genus Phlebotemus, which is widely distributed in tropical or sub-tropical regions.

Dr. A. T. (London, N.W.).—Fowler's solution was introduced into the British Pharmacopœia by Tom Fowler, an apothecary in Yorkshire.

MOSQUITOES IN EPPING FOREST.

In view of the danger to health caused by the large and increasing number of mosquitoes infesting Epping Forest, the Chingford Urban Council have called a conference of all the local authorities within the Epping Forest district to consider steps to abate the pest. Dr. Stanbury Brook, medical officer to the Chingford Council, recommends that where possible fish should be cultivated in the forest ponds to destroy larvæ, and states that the best way to attack the mature insect is to breed bats.

Dr. Alexander (Edinburgh).—Proofs of your paper will reach you this week.

L. S. R. (Halifax).—Is thanked, but the material is only remotely of interest to the readers of this journal.

Appointments.

Bride, T. Milnes, M.D.Vict., Hon. Ophthalmic Surgeon to the Northern Hospitals for Incurables, Manchester.

Hellier, John B., M.D.Lond., an Examiner in Midwifery and Diseases of Women to the Royal College of Physicians of London.

O'Brien M. A. A., L.R.C.P. and S.I., Certifying Surgeon under the Factory and Workshop Acts for the Fermoy District of the county of Cork.

O'Kelly, T., M.D., R.U.I., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Chipping Norton District of the county of Oxford.

Vacancies.

County of Lanark, District of the Lower Ward.—Tuberculosis Officer and Assistant Medical Officer of Health. Salary £300 per annum. District of the Middle Ward. Tuberculosis Officers and Assistant Medical Officers of Health (two). Salary £300 per annum. Applications to the District Clerk at Hamilton.

Preston County Asylum, Whittingham, Lancs.—Assistant Medical Officer, unmarried. Salary £200 per annum, with board, apartments, and washing. Applications to the Medical Superintendent.

Rainhill, near Liverpool, County Asylum.—Assistant Medical Officer, unmarried. Salary £200 per annum, with apartments, board, attendance, etc. Applications to the Medical Superintendent.

Gloucestershire County Council and Gloucester Corporation Joint Committee.—Tuberculosis Medical Officer. Salary £500 per annum. Applications to the County Medical Officer.

Durham County Sanatorium.—Medical Superintendent. Salary £400 per annum, with quarters and board. Applications to the County Medical Officer, Shire Hall, Durham.

Durham County Council.—Assistant Tuberculosis Medical Officer. Salary £300 per annum. Applications to the County Medical Officer, Shire Hall, Durham.

Birmingham General Dispensary.—Resident Medical Officer, unmarried. Salary £220 per annum, with apartments, fire, light, and attendance. Applications to the Secretary.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Aberfeldy (Perth), Boston (Lincolnshire), Glenavy (Co. Antrim), Pewsey (Wiltshire).

Berkshire Education Committee.—Assistant Medical Inspector of Schools. Salary £300 per annum. Applications to W. F.

Marriages.

Geikie Cobb—De Poix.—On August 12th, at St Edmund's, Bungay, Ivo Geikie Cobb, M.D., to Audrey, only daughter of Edmond Tyrel de Poix, J.P., and Mrs. de Poix, of Broome Place, Norfolk.

Grece—Maybury.—On August 14th, at the Parish Church, Frimley, Surrey, George Lewis Fitz-Clair, elder son of the late Clair James Grece, LL.D., Town Clerk of Reigate, Surrey, to Clara Maud, only daughter of Horace Mansell Maybury, M.D., of Islington, and grand-daughter of the late William Augustus Maybury, M.R.C.S.E., of Cedar Lodge, Frimley.

Loring—Cahill.—On August 16th, at Holy Trinity, Sloane Street, Norman Henry Loring, of 36a, New Cavendish Street, W., to Lucy Lilian, elder daughter of John Cahill, M.D., F.R.C.S., of 12 Seville Street, Lowndes Square, S.W.

MacNish—Wilson.—On August 11th, at All Souls, Langham Place, London, W., by the Rev. W. F. Scott, David MacNish, M.A., M.B., of Harley Street, W., to Margaret, widow of Herbert W. Wilson, of Liverpool.

Deaths.

Browne.—On August 12th, at Landour, Arthur Herbert Browne, M.B., C.M.Glasg., C.M.S., Medical Missionary at Amritsar, Punjab, from septicæmia.

Cran.—On August 12th, at Townfield House, Church Street, Great Harwood, Lancs, James Cran, M.B., C.M.Aberd., aged 57.

Cuthbertson.—On August 12th, at 22 Park Terrace, Stirling, David Cuthbertson, M.D.Edin., L.F.P.S.Glasg., aged 73.

Eastwood.—On August 11th, at Darlington, Lewis Eastwood, J.P., L.R.C.P. and S.Edin., L.S.A.

Makins.—On August 13th, at a nursing home at Blackpool, of acute pneumonia, Richard Makins, M.D.Glas., aged 35.

Miller.—On August 15th, at Elstead, Arden Road, Finchley, Frederick Montague Miller, M.R.C.S., L.R.C.P., late of Northolme, Upper Clapton, aged 65.

Noke.—On August 12th, at Northampton, Frank Herbert Noke, M.B., D.P.H., late Captain R.A.M.C., younger and only surviving son of the late Edward Noke, of 13 Springfield Place, Bath, aged 35.

Patterson.—On August 11th, at Constantinople, after a short illness, John Patterson, M.D., Mar. Coll. Aberd., L.R.C.S.Edin., aged 79.

Pritchard.—On August 11th, at 38 Nevern Square, Kensington, Dorothea Emily, daughter of W. G. Pritchard, M.D., Inspector of Hospitals, Madras.

Richardson.—On August 13th, at Aboukir, Warden Road, Totland, John Richardson, M.A., M.B., K.H.P., Surgeon-Colonel Indian Medical Service (retired), of Glenhurst, Fountain Road, Norwood, aged 76.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, AUGUST 27, 1913. No. 9.

NOTES AND COMMENTS.

The Control of Venereal Disease.

It is opportune that a special report upon venereal diseases by Dr. R. W. Johnstone should have been recently issued by the Local Government Board dealing with the essential remedies for their control. Public attention has already been directed to the subject through the discussion thereupon at the International Medical Congress, followed by the announcement of the appointment of a Government inquiry. It is pointed out that in the adult the influence of syphilis upon the public health cannot be measured by the official returns of certified deaths, which are well known to include only a portion of those even directly traceable to it. But even if the death-rate from syphilis and from diseases definitely ascertained to be of syphilitic origin could be ascertained and relied upon, the result would only represent a part of the damage caused to the public health by this disease. A most important section of Dr. Johnstone's report deals with the question of hospital and infirmary accommodation for sufferers from venereal diseases, which, unfortunately, is lamentably deficient. The poor syphilitic is not infrequently refused admission into hospitals sometimes because of some ancient by-law which would deny him the privilege of in-patient treatment. The sooner such a ridiculous prohibition is removed the better it will be for the public health. Greater facilities for the study and treatment of syphilis and gonorrhœa are urgently needed, and it is to be hoped, considering their national importance, that these affections may before long be earnestly grappled with by adequate legislative and administrative measures.

Sanatoriophobia.

From various parts of the country correspondents have written to several of the daily papers suggesting that the erection of sanatoria for consumptives at health resorts should not be allowed on the ground that tuberculous disease might be spread thereby. The idea that tuberculosis is an air-borne disease has no foundation in fact, for one has only to turn to the mortality statistics of places like Bournemouth or Nayland to see that the death-rate, instead of rising after a sanatorium has been established, has materially decreased. The sight of a large building with perpetually open windows does not scare the inhabitants of a place unduly, nor inspire the beholders with fear and dread of catching some disease. As the Mayor of Bournemouth has aptly expressed it: "The existence of these people congregated together does not affect the outside public. As to having a deterrent effect on residents or visitors coming to the town, I am of opinion that such effect is a practically negligible quantity. The establishment of sanatoria in Bournemouth has not adversely affected the town in any way. Bournemouth has always been regarded as a great health resort for chest complaints, and people of the district do not appear to think sanatoria are places to be avoided." It must be admitted that the popularity of Bournemouth or of Ventnor as health resorts has not suffered in the least degree in consequence of the presence of these buildings, nor can the view be upheld that their establishment would ruin a popular watering place. A mere sentimental objection to the presence of a sanatorium cannot be allowed to stand in the way of its erection in any suitable neighbourhood, whether this be thickly populated or not.

Coffin-Shaped Tablets.

There is much to be said in favour of placing poisonous lotions, liniments, etc., in bottles that are specifically different in shape from an ordinary medicine bottle. The appeal thus made to the senses of sight and touch is an extra precaution against fatal mistakes, especially where medicine is groped for in the dark, or in the case of semi-intoxicated or very ignorant persons. In spite of every care, however, disasters occasionally arise owing to gross neglect of the simplest precautions. It is reported that an American chemist has adopted the somewhat ingenious, if gruesome, device of making up dangerous drugs in coffin-shaped tablets, so as to impress patients with the peril of mistaking them for lozenges or sweetmeats. In the case of corrosive sublimate, for instance, there might be some sense in dispensing tablets of such a dangerous substance in such a sensational manner, but the difficulty of rendering the resulting solution, when dissolved in water, sufficiently distinctive as well would still remain. Besides, the shock to a sensitive patient in being confronted with an emblem of decease, even in miniature, might prove too much for his nerves, especially if the suggestion were adopted to stamp one side of the tablet with a skull and cross-bones. The dispensing and storing of poisonous solids as well as liquids can be carried out with safety if bottles of a distinctive shape and colour are employed.

Travelling Health Museums.

Some seven years ago an International Association of Medical Museums was founded with the object of developing the functions of the medical museum as a factor in medical education. The second triennial meeting of this association was held in London at the beginning of the present month, under the presidency of Professor A. S. Warthin, of the University of Michigan, who explained that the scope of the association really extended beyond pathology into every field of medical practice, more especially in the direction of preventive medicine and hygiene. There can be no doubt that there exists at the present day in our own country an increasing demand for medical museums upon a popular basis. The *rôle* of the travelling health museum, such as has been successfully employed in the campaign against tuberculosis, is more than merely educative; it awakens the public to a real sense of responsibility in connection with the presence of an infective disease in their midst. Judiciously staffed there is no reason why properly-equipped health museums of the caravan type should not be more generally used up and down the country to illustrate, for instance, the ravages of venereal as well as other diseases, for in this manner the claims of preventive medicine can be laid simply and convincingly before a large section of the public which it would be difficult to reach by other means.

LEADING ARTICLES.

THE MEDICAL PROFESSION AND TRADE UNIONISM.

THE recent decision at Brighton of the British Medical Association representatives against the proposal to form a professional trades' union demands careful consideration by medical men throughout the Kingdom. It cannot, of course, be regarded as final, for even if the rules of the Association do not permit the reference of a negative resolution of the kind to the final decision of members generally, the matter must infallibly be brought forward again. Under these circumstances it may be well to examine the position a little more closely, in order to see what is involved in the acceptance as well as in the rejection of the proposal. One of the main facts, so far as the Association is concerned, is probably that which enables a friendly society to trade upon a defined basis of profit and to further its particular objects by fighting legal actions bearing upon their collective interests. Among other financial considerations is the power of spending money in election expenses and maintenance of members of Parliament—a power that has been of supreme interest to the formation of the Labour party in the House of Commons. It would undoubtedly prove of incalculable value if the medical profession were similarly represented in the legislature. Many other of the statutory powers and privileges possessed by the friendly societies are already more or less completely in the hands of the British Medical Association. Take, for instance, the power of collective bargaining which is one of the chief weapons of the societies. That is possessed by the Association, as shown emphatically in the negotiations with the Government over the Insurance Act during the past few years. It is true that the weapon of the strike, which labour uses freely in its unceasing struggle against capital, is not, under present conditions, in the hands of Association members. As a matter of fact, the reason for its absence does not lie in the rules of the Association, but rather in the fact that medical men have not educated themselves to a recognition of the need of absolute self-effacement and loyalty to certain definite lines of collective policy. So long as workmen were a mere mass of isolated individuals they remained powerless and inarticulate; but by virtue of their friendly societies and trade unions they have rendered themselves a great and increasing power in the State. As a matter of fact, the British Medical Association appears to be to all practical intents and purposes already a trade union, and to describe it alternatively as a "voluntary Association" is a somewhat fine-spun distinction. The general sentiment underlying the representatives' rejection of the trade union proposal is that such a change would lower the status of the medical profession. It is somewhat difficult, however, to see that the medical dignity would suffer more than it did when the Association virtually declared a strike, although it was not carried out by members, who flocked to the panels at the close of 1912, in direct contravention of directions from headquarters and even of the pledges of members themselves. Nor can the attitude of the Association towards outside medical men be altogether regarded as that of an ordinary voluntary association; in some ways, indeed, it reflects the methods adopted by trade unions against non-members. In short, the parallel between the Association and the trade union is exact enough to prompt the average lay journalist to ask with his usual directness why a spade should not be called a spade. The answer to that question lies with medical men. If it can be shown that in trade unionism there is some undignified or coercive principle irreconcilable with the best traditions of the profession, there is in that case no need to make any change in the present arrangements. If, on the hand, the principles and practice of trade unionism, formally adopted *en bloc*, would strengthen the hands of a profession that is admittedly in need of advancement and succour, then it were mere weakness to ignore palpable facts and to decline a change of the kind on grounds that are mainly sentimental.

MYOPIA IN SCHOOLS.

UNDER the educational pressure in the elementary schools at the present time, the question of the prevalence of myopia among the children is becoming increasingly important. It was, therefore, timely to have introduced a discussion upon the subject at the International Medical Congress. A paper was read by Dr. James Kerr, of London, in the section of Hygiene and Preventive Medicine, upon the "causes, prevention, and treatment of visual defects in school children," which mainly dealt with myopia. This paper was followed by a long and interesting discussion, in the course of which many views were expressed, showing the cosmopolitan recognition of an evil which calls for repressive measures. There was one point upon which agreement seemed to be general, namely, that of the sex difference which existed in respect to the prevalence of myopia. Myopia, it was generally affirmed, was more common among girls than among boys, and the difference in regard thereto was attributed to the greater strain upon the near vision, such as that caused by needlework, which girls are required to undergo. It may be conceded that there is undoubtedly some truth in this, and there is reason in the supposition that whatever implies a greater strain upon the near vision, during the educational period, will increase the tendency to myopia. We must, however, at the same time recollect that myopia is a very complex subject. In its causation many factors are concerned, and in all probability the primary dominating influence associated with its development is an inherited tendency to the defect. Congenital myopia is almost unknown; the natural condition of the eyes at birth being hypermetropic. But myopia may be met with in children even before the school age has been reached. In these cases, as in others in which the defect develops early in life, the history is obtainable of shortsightedness in one or both parents—thus, under these circumstances, whatever the conditions may be under which a child is called upon to pursue the educational course, myopia will follow as an unavoidable result. Prevention, therefore, seems impossible of attainment, even under the most rigid precautions—in short, a child inheriting a pronounced tendency to myopia will become myopic merely by the ordinary use of the eyes in its daily life. Again, myopia is more commonly prevalent among girls, inasmuch as the inherited tendency seems to be transmitted to them in higher ratio than among boys. Undoubtedly, however, the influence of preventive measures, even in cases of a pronounced hereditary history, is salutary and useful. Although prevention may not be possible, there still remains the fact that to a large extent the defect can be kept under control by the constant use of the correcting lenses, and the avoidance of those causative influences which are known to be harmful. Myopes, however, in the first place require to be protected against themselves. Almost without exception they display an inveterate habit of using their eyes injuriously. They are always great readers; this pastime seems always to them to be irresistible; the question of suitable opportunities for doing so does not concern them—often they will be found poring over a book, aided by a light no greater than that emitted by the flickering flame of a fire—and yet it is a platitude to repeat that a good, sound light is as necessary for the near work of a myope as is wholesome air for the re-oxygenation of our blood. Parental restriction, therefore, should always be directed against this reprehensible habit of myopic children; and the children warned against the harmfulness of persisting in the practice of it. After the necessary correction of the defect with glasses, and the provision of a good light, comes the question of the size of the type employed in school books. The reading matter should, of course, be printed in clear type of a size which causes no strain to the children's eyes. Many educational books are printed in too small a type: in daylight this type might be sufficient for the purpose, but in the latter months of the year much of the teaching is done with the aid of artificial light, under the circumstances of which small type school books are undoubtedly harmful, by causing an unnecessary strain to the eyes. This matter has not hitherto received the attention its importance demands, either in regard to the school books of the elementary schools or those of private schools. A point raised by one of the speakers in the discussion invites some criticism. He expressed his abhorrence of the home evening preparation system, and claimed that it should be abolished. He also affirmed that in the winter months, from November till February, no class work should be done by artificial light. These suggestions seem to imply a passing from the sublime to the ridiculous. If these were to become educational laws, a large proportion of the educational life of the children would be lost—and wasted. Nothing is perfect in this world, nor is our education system perfect; but to attempt to legislate for that system in the manner suggested is equivalent to destroying the foundation upon which it rests. Neither the interests of the children nor of their parents would be advanced by a change so iconoclastic in origin.

CURRENT TOPICS.

The Dangers of Dust Heaps.

The complexity of infections associated with dust heaps, and the loathsomeness of their decomposition effects, constitute a menace to the public health wherever they exist. A noticeable concrete example of this has just been furnished by Dr. Bruce, medical superintendent of the Southwark Infirmary. During the past few weeks an outbreak of enteritis occurred in the infirmary among eighteen children, of whom four died, and the cause of the disease was directly attributed to the laden trucks of dust refuse on a railway siding adjoining the infirmary. This dust refuse was, under the authority of the Camberwell Borough Council, being removed by the contractors. The nuisance had already been made the subject of frequent complaint by the Southwark Board of Guardians, but hitherto no attention had been paid to their protestations, with the result that four children have now lost their lives. It would seem as though the members of the Camberwell Borough Council are immune from the ordinary dictates of humanity. Why should any arrangements they choose to make for the removal of the borough refuse, albeit detrimental to the health of an adjoining parish, concern them? This would seem to be their process of reasoning, ignoring the fact that they are no more entitled to poison their neighbours than their neighbours would be entitled to poison them. Obviously the persistent neglect to abate the nuisance can be in no way justified. The preservation of the public health in one parish is just as important as its preservation in another, and anything which detracts from that necessary consummation must be strenuously dealt with, not only in the interests of the parish concerned, but in those of the community as a whole. The matter, we learn, is now to be submitted to the Local Government Board with a view to compelling the Camberwell Borough Council to do their plain duty, failing this legal proceedings will be taken, the costs of which the ratepayers of Camberwell will doubtless be called upon to pay. And so it is that public money is ruthlessly wasted.

Spitting.

Shakespeare tells us that "orators when out will spit." He understates the case unless there is something in the spirit of the British workingman that bids him rival Demosthenes, and makes him treat an atypical *trait* as a specific sign of rhetorical ability. Anyway, street-corner politicians and house-supporters spit strenuously. Tobacco-chewing is their exercise and expectoration their lighter amusement. Our public bodies, who know that tuberculosis, pneumonia, and sometimes cerebro-spinal meningitis, are thus spread, print little notices that say, politely, "Please do not spit." Their effect is probably *nil.* The mental equipoise of the classes they are meant to reach is not in the least disturbed. Rather the opposite. Our corner-boy sees the notice and is reminded that he can spit if he likes, and promptly does so in a spirit of manly independence characteristic of the free-born Briton. What is really wanted is a bye-law, and it affords us pleasure to record the fact that at least two towns already have it. In Birmingham and Southport the casual sputum-scatterer may be fined. We hope he is. His habit is a nasty one, æsthetically offensive and dangerous as well, and should be quenched with all convenient rapidity. Precept upon precept has been tried and found wanting; fine upon fine may have more effect. We must keep hammering away, and when we know that only he is blessed that expectorates nothing, we shall not be disappointed.

Nurse.

We are quite used to nurses. In our student days they were common objects of the hospitals we used to walk, and after we had recovered from the primary fascination of frill-less femininity, we realised that they were people who could do things. We now think of them as handy things to have about our patients' houses. Our relationship to them is clear. Like the centurion, we say "Do this," and she doeth it. So do the rest of the household. We are autocrats, and they must obey. We forget that our subordinates act and interact on each other. The status of nurse to patient's family is a peculiar one. It is like the doctor's, in that each renders personal service for pay, while the employer is under the control of the employed. Doctors were once ranked a little lower than body servants, but have raised themselves by improving their standard of work till it was out of reach of the menials. So with nurses. A few years ago they were below the maids, and recognition of their attainments does not come in a flash. They, too, like any doctor, must turn their hands to the lowliest work in humble homes. And so we find their function often misunderstanded of the people, who are apt to use them like dictionaries—consulted and bowed down to when information and help is wanted, and then shut up and put back in their place. It is for us to see that this does not happen if we can help it, as the net result is not one calculated to help our patient, but people take a great deal of educating before they are fit to have a sick person in the house. The ideal nurse is much more easily achieved; the trouble with her is that as soon as she approaches perfection someone realises it and marries her.

Oysters in Health and Disease.

That "seductive bivalve," the affectionate term applied to the oyster, is about to be with us again, to our delight and satisfaction. The fact that the oyster season once more begins next month seems to suggest a few reflections upon the favour enjoyed by this especially popular article of food. Although regarded universally as a luxury it is nevertheless a nutriment of great value, consisting, as it does, of ten per cent. of protein in a highly assimilable form. In addition it contains phosphorised fats and glycogen, while the salt absorbed in its tissues acts as a direct stimulus to the gastric secretion. Thus a French observer has recently pointed out that in certain diseases its action is especially beneficial, mostly in conditions in which disturbed gastric function is a prominent feature. As a stimulant to digestion, in anæmia, dyspepsia, during convalescence after infective disease, atony of the stomach, and gastric ulcer, oysters may be highly recommended—and this prescription, by the way, is one to which patients usually would not be likely to object. Still there is a class of dyspeptics, those whose gastric secretion does not require stimulation, to whom oysters would not be indicated, either for dietetic or therapeutic purposes. Among these persons gastric hyperacidity or hypersensitiveness prevails, to which the special dietetic properties of the oyster would tend to add, thus proving harmful in its effects. While, however, the oyster is undoubtedly a valuable article of diet in disease, the fact remains that the subtlety of its attraction can only be fully appreciated by the healthy person—the man who would be glad if his pharynx extended five miles in length in order to afford him time to grasp the delicacy of the flavour.

Gastric Ulcer and the Bacillus Coli.

Apropos of the idea expressed in the Address in Surgery at the annual meeting of the British Medical Association at Brighton that some infection in the vermiform appendix or its immediate vicinity might be the cause of gastric ulcer, it is interesting to note that some experimental evidence is forthcoming in support thereof. It has been stated by Sir Berkeley Moynihan that some quiescent inflammatory lesion of the appendix seems especially potent and persistent in playing the part of an infecting agent in relation to gastric and duodenal diseases. Dr. Edgar C. Steinharter, of Cincinnati *(a)*, has recently demonstrated that gastric or duodenal ulcers can be produced in rabbits by the intravenous injection of clumped colon bacilli. In a preliminary note he records the fact that an injection of 2 to 3 c.c. of an emulsion in broth of active strains of the *Bacillus coli,* agglutinated with weak solutions of acetic acid and hydrochloric acid, into the ear vein of rabbits was uniformly followed by the formation of a gastric or a duodenal ulcer within 24 hours. It is not unnatural to suppose that such ulcers might be formed in man under analogous conditions. At any rate, this observation shows the importance of the colon bacillus as a factor in the production of necrotic lesions. Further developments of these investigations will be awaited with interest by pathologists, physicians and surgeons alike.

A New Drug.

In the report for 1912 of the British Consul for the district of Harrar in Abyssinia, allusion is made to a drug, peculiar to the district, known as "kat," of which use is commonly made by the natives. According to the observations of Mr. Dodd, the Consul in question, the consumption of the drug is confined to the male members of the Mohammedan population, while the true Abyssinian does not use it. The evidence shows that the drug has a temporary stimulating effect which, however, soon passes off, and is followed by a listless state, a loss of appetite, and insomnia. Chronic "katism" implies poor physique, indolence, and lack of intelligence, features which are transmitted by hereditary descent. A drug of such active potency might be made the subject of pharmacological and therapeutic research, and its physiological effects submitted to experimental investigation. Possibly "kat" might contain, despite its apparently noxious properties, certain attributes which might prove of extreme value for therapeutic purposes. Therein lies the interest of the discovery of a new drug. It is never possible to foretell its therapeutic possibilities until its action has been determined by scientific research. Then it is that surprises may be forthcoming, and a new drug may then come into vogue with a clatter of applause, supplying a want which had hitherto been unfilled. We do not say that there is anything in "kat" of this nature; precisely what seems to be understood by "kat" is the "young and succulent leaves of a small tree which in appearance is not unlike the coffee bush." Its properties apparently are those of a narcotic—similar to, though more potent than, opium. At least "kat" must contain an alkaloid, the physiological properties of which it would be interesting to determine.

The Pathogenesis of Salvarsan Fatalities.

There is always a tendency on the part of some critics to over-rate the drawbacks of any new remedy, and salvarsan is no exception to the rule. What with specific effects upon the nerves of special sense and the latest "bogey" of hæmorrhagic encephalitis the devotees of "606" have as much as they can do to answer the objections of those who would seek to put back the clock of syphilographic progress. In the opinion of high experts, such as Dr. W. Wechselmann,(a) the majority, if not all, of the fatalities from salvarsan injections are nearly always due to some error in *technique*. The entire experience of this author with more than 25,000 injections leads him to the conclusion that salvarsan is less toxic than mercury. With an exact *technique*, the careful adaptation of the dose to each individual case, the observation of the urinary secretion, and the cautious use of mercury after the last injections, a fatal issue with salvarsan should become a greater rarity than ever.

Should Diachylon be Scheduled?

The practice of taking diachylon by women who wish to avoid the inconveniences of pregnancy appears to have first obtained in the neighbourhood of the "Potteries" district of North Staffordshire. It is well known that in the past this centre has been quite a notorious seat of industrial lead poisoning. A few years ago cases of poisoning from the administration of diachylon as an abortifacient were comparatively frequent, so much so that pressure was brought to bear upon the Government to schedule this substance as a poison. The question has been recently brought up again by Dr. Arthur S. Hall, of Sheffield, in a valuable paper read before the Section of Forensic Medicine of the International Congress of Medicine, who has pointed out that the practice is again assuming such proportions as to demand prompt and strong repressive measures. It appears that the practice of dealing in diachylon pills is supplemented largely by the handing on of the information from woman to woman, and there seems no doubt that it is in this way the practice is chiefly spreading. Many of the women suffering from plumbism have admitted that they were not pregnant at all, and that they were told to take diachylon in order to prevent them becoming pregnant. In most cases it is impossible to find out where the pills have been obtained; and, as a matter of fact, it is more commonly the information that a pennyworth of diachylon divided into bits and taken several times a day will produce the required result, which has alone been received from a friend. The women who are keeping up this practice are stated to be of the ignorant class. They do not know that plumbism causes death of the fœtus, or that diachylon causes plumbism, nor, in many cases, that diachylon contains lead at all. Such knowledge amongst this class is limited to the very few areas where there are lead industries. The practice has extended far beyond these areas now, and to the bulk of the women in these outside areas their knowledge of the matter begins and ends with the one word "diachylon." Were the sale of the article checked, or, even better, entirely prohibited, no one would suffer thereby, and a large part of this dangerous practice would cease entirely.

PERSONAL.

H.M. the King has been pleased to give directions for the appointment of Mr. Fitzmaurice Manning (Deputy Principal Medical Officer) to be Principal Medical Officer, Northern Nigeria; and of Mr. Thomas Hood (Deputy Principal Medical Officer) to be Principal Medical Officer, Southern Nigeria.

Dr. T. Glover Lyon has been elected a Warden of the Barbers' Company.

Mr. James Adamson Bell, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer to H.M. Prison, Gloucester.

Dr. G. I. T. Stewart, C.M.O., has been appointed Chief Tuberculosis Officer to the East Suffolk County Council.

Dr. G. S. Trail, of Strichen, was the recipient the other day of a suitable testimonial in recognition of his services as Secretary of the Buchan Medical Society for twenty-five years.

Dr. Thomas Henry Peyton, Tuberculosis Medical Officer to the County Council of the West Riding (Wakefield District), has been appointed to a similar position for the County Palatine of Chester.

Sir Arbuthnot Lane, Bart., M.S., F.R.C.S., will deliver the opening address of the winter session of the North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham) on Thursday, October 23rd, to which all qualified practitioners are invited.

The Lancashire County Council have appointed the following three whole-time Tuberculosis Officers:—Mr. Edward H. A. Pask, M.D., B.S.Lond., at £500 per annum; Mr. Burgess MacPhee, M.B., Ch.B.Glasg., at £400 per annum; and Mr. J. Logan Stewart, M.A., M.B.Glasg., at £400 per annum.

CLINICAL LECTURE

ON

ACQUIRED MENTAL DEFECT. (*a*)

By A. F. TREDGOLD, L.R.C.P.Lond., M.R.C.S.Eng.,

Consulting Physician to the National Association for the Feeble-Minded, &c., &c.

Gentlemen,—Persons suffering from mental defect may be divided into two groups In the first, which embraces between 80 and 90 per cent. of all cases, the defect is an intrinsic one; that is to say, it is due to an inherent blight, a deficiency or pathological change in the neuronic determinant of the germ plasm, in consequence of which the cortical cells concerned with the manifestation of mind are unable to attain complete development, so that there results a varying degree of amentia. This group has usually been described as "congenital"; but although the condition is inborn, it is not necessarily manifest at birth; it may not be apparent until several years after birth, and hence I think the better term is that of *intrinsic* or *primary* mental defect.

In the second group there is no morbid heredity and the germ plasm is healthy; but the development of the cortical cells of the brain has been interfered with by some external influence, some factor of the environment. The mental defect which results is thus accidental or acquired, but since it may be acquired before, as well as after, birth, I prefer to use the term extrinsic or secondary for such cases. It is with the group of *acquired, extrinsic* or *secondary* mental defect that I here propose to deal.

As I have just stated, the group is a relatively small one, probably comprising not more than between 10 and 20 per cent. of all cases of amentia; but amentia is so common that even this proportion means a very considerable number of patients. Moreover, the possibility of amelioration is so dependent upon early diagnosis as to make the group one of great importance as well as of no little interest to the practitioner.

The external factors which may in this way produce arrest of mental development are very numerous, and the pathological conditions found in the brain after death are of the most diverse nature. Nevertheless, it is possible to divide the group into certain classes, and I shall accordingly consider acquired mental defect under three headings, namely: (1) Toxic; (2) vascular; and (3) nutritional.

Class I. Amentia due to Toxic Causes.

The class I shall first consider is that in which the arrest is produced by toxic agencies. As you are well aware, there are many substances which act as poisons upon certain of the body cells. For instance, there is the inorganic group, well-known examples of which are arsenic, lead, and phosphorus. There is the organic group, familiar instances of which are alcohol, carbon-monoxide, hydrocyanic acid, etc. Lastly, there is the group of toxins produced by micro-organisms. It is these last which we find to be chiefly concerned in the causation of mental defect.

In most cases they would appear to bring about a real poisoning and necrosis of the cortical cells, but inflammation is generally present as well, so that the clinical signs of the process are those of an acute encephalitis, meningitis, or meningo-encephalitis.

There are many micro-organisms which may act upon the brain cells in this way. For instance, the pneumococcus, gonococcus, various streptococci and staphylococci and the bacillus of influenza are all capable of causing inflammation and necrosis of cortical cells. In such cases the affection of the brain is usually secondary to some acute process elsewhere, such as inflammation of the lungs, influenza, otitis, rhinitis, etc. More often, however, the affection of the nervous system would appear to be a primary one and to occur independently of lesions elsewhere, and then it is probably either a cerebral or cerebro-spinal meningitis caused by the diplococcus intracellularis of Weichselbaum, or, as described by Strümpell, it is a polio-encephalitis analogous to the acute inflammation of the anterior horns of the spinal cord occurring in children. I am inclined to think that many cases of meningitis of obscure origin and many cases of so-called "sunstroke" and even "fright" really belong to one or other of these last two groups.

The clinical course of the illness is variable. In a proportion of cases prodromal symptoms are present, the child being listless and suffering from malaise for two or three days before any cerebral symptoms make their appearance. In most cases, however, the onset is much more rapid and he is suddenly seized with headache, vomiting and fever, speedily followed by convulsions or unconsciousness. The pain in the head is usually a marked feature, being very severe; pain in the back also is often complained of. The respiration is apt to be slow and irregular; the pulse may be slow or rapid, but is usually weak. The convulsions are general, and resemble those of epilepsy; sometimes they are continuous, so that a status epilepticus results; but in other cases they occur as isolated fits, the patient being either delirious or comatose between whiles. The symptoms follow no definite course and differ considerably in different patients, but they are always such as to make it quite obvious that the child is seriously ill and that the seat of the trouble is the brain or its meninges. These symptoms are practically the same whether the brain is affected primarily or whether it is involved in the course of some other condition, such as influenza or pneumonia.

In a few, but I think a very few, cases the child recovers completely. In others, after an illness of ten or fourteen days, there is a marked change for the worse; the pupils dilate, the pulse and respiration become more irregular, the coma deepens and the patient dies; sometimes the end comes after a series of convulsions. But neither of these terminations concerns us; there is a third result, and these are the cases to which I wish to draw your attention. The patient's life is spared, but the illness has left an indelible mark upon the brain cortex, with the consequence that he suffers from some degree of mental defect.

(*a*) A lecture delivered at the Medical Graduates' College, London, Feb. 26th, 1913.

In most cases where the brain tissue has been thus damaged, the mental change is noticed at once. If the child had begun to speak, he may now be speechless. His disposition may be altered, so that the persons, the playmates and the games of which he was formerly fond are now distasteful to him. With this there is either unusual irritability or apathy and dulness, and examination speedily shows the presence of intellectual impairment. As time goes on this is seen more and more in the difficulty he experiences in learning. In a few cases recovery from the illness at first appears to be complete, at any rate to the parents, and it is only after a time, when the child begins to go to school, that he is found to be incapable of mental application and of progressing with his studies. Incurable deafness is not uncommon in cases of this kind. With regard to the degree of defect, the brain lesion may be so severe that the child is rendered idiotic from the beginning; in other instances it is much less serious, but the patient cannot keep abreast of his compeers, and as time goes on he is left further and further behind in a state of incurable feeble-mindedness. I cannot say what proportion of children who have suffered from encephalitis or meningitis are thus rendered permanently weak-minded. No doubt, as I have remarked, very many of them die, whilst a few seem to recover completely; but the likelihood of interference with brain development is so great that the utmost caution should be exercised in giving a prognosis. It will be more convenient to discuss the factors influencing our opinion after we have considered the next class.

Class II. Amentia due to Vascular Lesions.

In addition to the arrest of cortical development brought about by toxins, cerebral lesions may be produced and growth interfered with by such vascular changes as hæmorrhage, thrombosis and embolus. It is this class we have now to consider.

The commonest of these lesions is undoubtedly hæmorrhage. Thrombosis occasionally results from asphyxia neonatorum, and embolus may occur in young infants suffering from rheumatic endocarditis, but both of these are comparatively rare. The hæmorrhage is generally meningeal, and usually takes place at the time of birth, being caused by the prolonged pressure incident to a protracted labour. The forceps have often been blamed for the bleeding, but it is very doubtful to my mind whether skilfully applied forceps have ever of themselves produced serious injury to the brain. Rupture of a cerebral blood vessel may take place during a severe paroxysm of whooping cough, and at times it follows direct trauma in the shape of a fall or blow. This last may occur before as well as after birth, and may be accompanied by laceration of the brain cortex.

In the great majority of the birth cases, which is by far the most numerous group, the child presents well-marked asphyxia when born, from which he is resuscitated with considerable difficulty. For several days he remains torpid, with feeble pulse and respiration, tense anterior fontanelle and contracted pupils. He does not cry, and requires much rousing before he will take food. His muscles are rigid, opisthotonos may be present, and convulsions are frequently seen. A little later on evidence of paralysis in one or more limbs is noticed. Sitting up, walking and speech are all delayed, and it is soon evident that the child's mind is not developing as it should. As time advances, the fact that his intellect is impaired becomes more and more obvious.

Paralysis is a very common feature of these cases, and the condition is often termed "paralytic amentia." It may be a monoplegia, hemiplegia, diplegia or paraplegia. Probably diplegia and paraplegia are really the most frequent lesions, but since these mean a very severe affection of the brain, the majority of such cases die with the first few weeks or months of life, and hence it is a monoplegia or hemiplegia that we usually see in association with this variety of mental defect. In addition to the paralysis the affected limb remains livid, cold and much smaller than the corresponding healthy one. Jacksonian or epileptic convulsions occur in a considerable proportion of these cases, and athetoid or choreiform movements are very common. There is usually some flattening of the skull over the affected side. The degree of amentia varies from gross idiocy to mild feeble-mindedness.

These two, the toxic and the vascular, are the commonest varieties of secondary or acquired amentia, and to one or other of them you will be able to refer the great majority of cases of mental defect which are not of intrinsic origin. I have dealt with them separately up to this point, because it seems to me important that we should understand their different modes of origin, but we may now consider a few facts applicable to both of them. And first of all it is worth bearing in mind that the lesions seen upon the *post-mortem* table long after the incidence of the initial pathological process generally differ very considerably from those at the beginning. We do not yet know all the factors bringing this about, but it is quite certain that many secondary changes may result, so that in one case we find areas of sclerosis, with shrinkage, in another chronic meningitis, cortical agenesis and heteropia, cysts, porencephaly, hydrocephaly, or the like. Sometimes these give rise to more or less distinct types, which may be recognised clinically, but it must be remembered that these lesions are after effects only and that the real cause of the defect is the destruction of a cortical area, to which may be added an arrested growth of those parts of the brain which are anatomically connected.

With regard to the diagnosis of these cases, if several months or years have elapsed since the incidence of the primary lesion, there will seldom be any difficulty. If real defect is present it will readily be ascertained by a psychological examination on the lines I have indicated in a previous lecture, and that the defect is of the secondary variety will be shown by the absence of any neuropathic heredity and by the presence of a history of a toxic or vascular lesion like those I have described. The mental defect may be of any degree, and although idiocy usually reveals itself by its characteristic physiognomy, it is well to remember that those patients who are merely feeble-minded or even imbecile may have the outward appearance of ordinary individuals. This arises from the fact that the germinal material is healthy, the defect is merely accidental, and consequently is unaccompanied by any of those anomalies of bodily development—stigmata of degeneracy—which are such a distinctive feature in cases of primary amentia. Persons suffering from acquired mental defect are, indeed, as remarked by Langdon Down, often "well-grown, comely and winsome."

If the case is seen at the onset the matter is very different, and you will often find it exceedingly difficult to answer the parents' anxious enquiry as to the likelihood of intellectual impairment resulting.

Of the children born with asphyxia, the number in whom amentia results is extremely small, and careful observation of the child for a few days will usually enable the physician to reassure the parents on this head; unfavourable symptoms are convulsions, extreme torpor or persistent screaming. Of the toxic cases happening during early childhood, the proportion who become aments is much larger, and this possibility can never be excluded with certainty until the lapse of some time after the illness. It is very fallacious to judge of the probability of mental impairment from the presence of paralysis, whatever the nature of the lesion. Should paraplegia or diplegia be present it is true that there will probably be some degree of incurable mental defect, because this means that both hemispheres have been involved, and it is obvious that the greater the extent of the lesion the more likelihood will there be of psychic injury. But, apart from this, the mere presence of paralysis is a very uncertain indication. I have seen many instances of severe hemiplegia in which the children grew up, not merely non-defective, but of unusual brightness and intelligence; conversely I have seen profound secondary amentia, caused by a birth injury or toxic infection, without any trace of paralysis. No doubt these differences have been due to the particular cortical region which has been involved by the morbid process.

The symptom of most unfavourable import is undoubtedly epilepsy, and if convulsions continue, even at comparatively rare intervals, after the fever has subsided and the child has recovered from his original comatose condition, then the mental outlook is very serious. I do not mean to say that in every case which is followed by occasional epileptic fits, even if some paralysis be present as well, the prognosis as regards improvement is necessarily hopeless. This is not so, but it is an undoubted fact that in the larger proportion of these cases in which epileptic convulsions occur mental impairment will result, and only too often to a severe degree.

This leads me to say a few words regarding *epileptic amentia*. In the cases I have just referred to, both the amentia and the convulsions are the result of a common cause; they are, in fact, symptomatic of, and produced by, a gross cerebral lesion. It often happens that at first the fits are Jacksonian in character; later on, however, they tend to become generalised and to resemble those of ordinary idiopathic epilepsy. But idiopathic epilepsy, that is epilepsy occurring in the absence of any demonstrable morbid anatomical condition, may itself give rise to mental defect, and it is to defect so caused that the term "epileptic amentia" is applied. You are well aware that repeated epileptic attacks, whether of the minor or major variety, are very liable to degrade the intellect and produce some degree of dementia; consequently you will readily understand that should these attacks occur at an age when mental development is still incomplete, they will be very liable to arrest that development and so produce secondary or acquired mental defect. If epilepsy occurs before the age of 5 years the probability of development being thus arrested and some degree of defect being produced is very great. Much, however, depends upon the frequency of the fits and their response to treatment. I have seen several cases where marked arrest was present, but where the successful treatment of the epilepsy was followed by a considerable improvement in the mental status. I may here remark that it is sometimes stated that mental defect may follow "shock" or "fright." Undoubtedly such causes may bring about arrest in those hereditarily predisposed, but I doubt whether they are ever capable of so acting in a normal child.

Before leaving these two varieties of defect let me add a few words regarding their treatment. Speaking generally, it may be stated that if the case is really a secondary one, and not a case of primary amentia complicated by a gross cerebral lesion, there is a probability of a fair amount of improvement under proper educational methods. And on the whole I am inclined to think that the prospects of amelioration are better in lesions of purely vascular than in those of toxic origin. This may partly be due to the fact that vascular lesions generally occur during birth or at an earlier age than those of a toxic nature; but it may also be due to some extent to the difference in the pathological process.

It might, perhaps, be thought that benefit would result from some surgical procedure, and as a matter of fact, parents are often very anxious for the performance of an operation. I must confess that I have very little experience of the effect of operation in such cases; possibly, if one could diagnose the presence of a blood clot and locate its position, operation might be undertaken; but in other cases, in view of the nature of the lesion, it is difficult to see how this could possibly be of any benefit, and I should certainly be very loth to recommend it.

Whatever the nature of the morbid process, its effect is, in most instances, to destroy, or arrest the development of, a group of cortical cells and their ramifications, and treatment must be directed, firstly, towards limiting the lesion, and secondly, towards educating other cells to perform the work of those which have been rendered *hors de combat.* With regard to the first of these desiderata, I doubt whether drugs are of much use. I have frequently prescribed iodide of potassium, also mercury, in view of their supposed resolvent action, but I much doubt whether they have had any real effect. More can be done, I believe, by careful attention at the first to avoid undue light, noise, movement or any external stimulus which might increase cortical excitement. The condition of the bowels requires attention, and when recovery is taking place abundant sleep is essential; it should be obtained by paraldehyde or the bromides in preference to opium. A little later, plain nutritious feeding is needed, and I think that iron, arsenic and the glycerophosphates sometimes prove of value in assisting cerebral nutrition; strychnine must be given with the greatest possible caution.

Provided the lesion has happened while the cortical cells are still in an early stage of structural development, there is, to my mind, some evidence that compensation may occur through the development of other neuroblasts to take the place of those which have been destroyed, and this supplies the indication for our chief treatment, namely, regular, systematic training. I do not propose to go into the details of this; it can only be carried out properly by a skilled, patient teacher acting under the constant supervision of an expert who is capable of forming an opinion as to the nature of the psychic injury and the most appropriate methods of remedying it. This much, however, is certain, that training of this kind is absolutely necessary if improvement is to result, and that it must be begun at the earliest possible moment. No more fatal plan can be adopted than the, I am sorry to say, only too common one of deluding the parents with the fond hope that all will come right with the lapse of time and that the child will grow out of it "when he is seven."

Class III.—Amentia Due to Nutritional Defect.

The last group of cases to which I wish to direct your attention are those in which the growth and development of the brain are defective in consequence of inadequate nutrition. Like every other organ in the body, the growth of the brain is dependent upon two influences; firstly, a tendency inherent in a certain portion of the fertilised germ cell to grow, to proliferate and to become differentiated into various orders of nerve cells, each having its own particular connection and peculiar function; secondly, upon the presence of a nutritive material adequate in quality and amount.

Now it must be confessed that at present we know very little regarding the nutritive requirements of the various bodily organs, but it seems certain that the brain, at any rate, requires for its growth certain particular chemical constituents, and if these are lacking, the normal development cannot take place. We then have a form of amentia which I have called "Nutritional."

One of the most interesting and best known examples of this variety of defect is *cretinism*, which is due to an inadequacy of the secretion of the thyroid gland. The cause of the athyroidea we do not yet know, neither do we know whether it is some particular constituent or the whole of the secretion which is necessary; but that the brain cells cannot attain full development if this secretion is wanting is quite clear; consequently all cretins suffer from some degree of mental defect. We see a similar effect upon cerebral nutrition in the myxœdema occurring in later life. The signs and symptoms of cretinism are so well known to you that no description is necessary here; I merely mention it as a very interesting example of the group of acquired mental defect due to defective nutrition.

There is another very interesting type of amentia known as *mongolism*, which is often mistaken for cretinism, although a close examination will readily show the difference. The pathology of this condition is very obscure. Heredity seems to play some part, although perhaps a slight one; and in most cases there are indications of exhaustion on the part of the maternal generative organs. It may eventually be found that here also there is a deficiency of some internal secretion which is vital to the development of the brain.

Leaving these specific deficiencies, let us now consider the question of the effect of general bodily malnutrition upon mental growth. The statement is commonly made that the defective nutrition and the insanitary surroundings which *inter alia* form part of "slum life" are responsible for mental defect. So far as my experience goes this is very rarely the case. I have seen instances, it is true, where the normal evolution of the mental faculties has been considerably in arrears in consequence of such conditions. I have seen a few cases where these arrears have never been made up, so that some degree of real amentia has resulted. But such cases are relatively few, and if you can exclude the presence of any hereditary tendency, you may reassure the parents, for as the bodily condition improves under good feeding, sunlight and fresh air, combined if necessary with suitable medicaments, the mind will undergo a like change.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Robert Knox, M.D., Director, Electrical and Radio-Therapeutic Department, Cancer Hospital; Honorary Radiographer King's College Hospital. Subject: "Radium in the Treatment of Malignant Disease."*

It is estimated that the adulteration of food costs the British people annually £66,000,000 and that each person is defrauded of a penny a day.

ORIGINAL PAPERS.

APEX-TREATMENT FOR PULMONARY CONSUMPTION.

By WILLIAM EWART, M.D.Cantab., F.R.C.P.,

Consulting Physician to St. George's Hospital and to the Belgrave Hospital for Children; formerly Assistant Physician and Pathologist to the Hospital for Consumption, Brompton.

(Concluded from page 196.)

VII.

THE USES OF UNILATERAL BREATHING IN TREATMENT; AND OF THE CHEST-CLIP FOR DIAGNOSIS.

It is not likely that the mechanical principle underlying this simple utilisation of a natural function will ever cease to be of use in preventive apex-culture; more probably developments may arise from it which we do not foresee. Possibly in some improved shape the chest-clip may find a permanent place in actual treatment. For the present it can only claim to be an addition to our armamentarium for clinical study; a handy means for settling the all-essential question, "Shall we rest and deflate, or shall we freely ventilate the torpid and already slightly tainted apex"? Its other clinical purpose, as we shall presently show, is to assist our early diagnosis.

For therapeutic use, as a modifying regulator of apical breathing, it offers obvious advantages. Unlike Tidey's strapping, it is "off" as quickly as it is "on," and is immediately transferable from one side to the other. Its action is definite, adaptable, and measurable. Locally its pressure gives effectual rest at any time we may deem rest desirable. Or, if we simply shift it to the sound side, it will gently exercise the affected apex with unilateral breathing. Which shall we try, its resting or its exercising function?

The answer is, that all things are good and bad according to their regulation. That facility is a feature of this application of the differentiating local apex principle. We can finely graduate both the rest and the exercise, by using springs of different strengths.

The trend of practice is distinctly swerving; and the policy of rest has already been largely departed from. Paterson gives graduated labour even to the open stage; and Forlanini treats it in the surviving apex by doubling the pulmonary work. Nature, too, had always conducted her early spontaneous cures by keeping the lung and the heart at work as usual; whilst we have always exercised both of them strenuously for prevention. Nevertheless we might easily go too far or too fast in this new direction. It is equally certain that rest has its sphere, and that its indications have not yet been clearly determined. Probably they are not to be defined by rule in any individual. Therefore the chest-clip might be of some use as a ready *individual test* as to fitness for the "exercising" stage in treatment.

In pneumothorax the absolute unilateral breathing special to it is applied "full strength" to any early lesions in the working apex, although the safety of that lung is life's only safeguard. This is our justification for resorting tentatively to a similar, but less forcible method, under non-precarious conditions, and where there is a second working lung in reserve, namely, a perfectly healthy lung. That trial is safe; and it is our only means of solving the fundamental question as to the proper management of the earliest stage.

For preventive use that full strength is never applied or indispensable. "Relative" unilateral breathing is much less potent, but there is no limit of time or frequency to its beneficial employment, even in the cradle where we can alternate the lateral decubitus, or at the preventorium or open-air school where the clip might exercise both apices alternately in all cases of the phthinoid chest.

The Chest-Clip. (*a*)

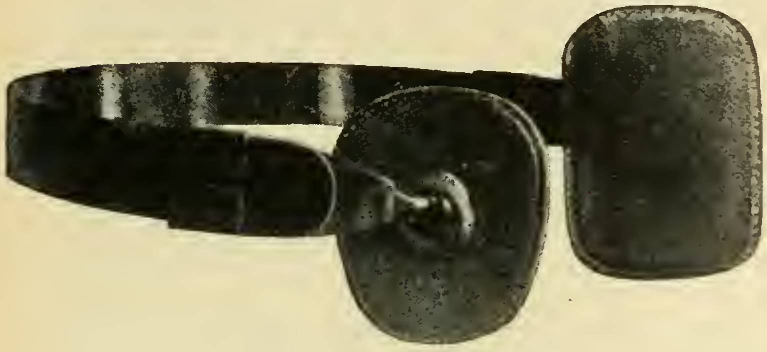

Fig. 2.—(*b*) Showing the ball-and-socket attachment of the heart-shaped front pad, and the sliding attachment of the spring.

The chest-clip is a light ribbon-spring of elongated horse-shoe shape, and of sufficient length to extend round one half of the chest from the spine where its spinal pad gives it a fixed bearing, as far as the parasternal region, where its pectoral pad exerts its pressure. The pads are easily removable to fit other springs of different length and strength, and the ball and socket-joint with which they are furnished enables the front pad to be applied to different points of the upper pectoral surface. In addition to the localised pressure exercised at any point selected, the effect of the spring is to restrain the respiratory movement over the upper part of that side of the chest, and to increase it over the other. It is, moreover, found that the lower part of the chest is concurrently influenced in the same manner. As it is easily slipped on and off under the coat or shawl, the chest-clip is a convenient means of modifying the type of breathing for varying periods and in varying degrees, and of raising or lowering the respiratory activity of one or the other apex.

By keeping at relative rest the affected apex, it enables the patient to take exercise and full breaths without throwing any additional respiratory stress upon the damaged apex. The opposite results would follow were the spring to be applied to the sound side; a more or less unilateral increase of breathing would occur at the seat of the lesion. In artificial pneumothorax, that is precisely, on a much larger scale, what happens to the working lung, which is most often already slightly affected; but the unilateral breathing is then "absolute," as there is no breathing whatever on the other side. It might be said of the "relative" unilateral breathing set up by the chest-clip that it represents one of the two factors of the cure by artificial pneumothorax, namely, the mechanical; but it does not represent on so large a scale the other contributory factor, the suppression of toxis.

The Chest-Clip in Diagnosis.—Whilst the therapeutical value of unilateral breathing, and of the chest-clip which is identified with it, still remains an open question, there can be no doubt as to the great value of the appliance for *diagnosis*. In its primitive form, as a simple spring guarded at both ends by leather, (*a*) I have used it constantly for the last three years for the sake of utmost economy of time combined with utmost definiteness in conclusions. The advantages to be gained need hardly be explained to experts. It solves the difficulty of the personal respiratory factor in the patient, namely that of his uncertain response to our attempts to obtain the different degrees of respiration we require, and of the confusion which arises therefrom. The first step is an examination of the chest as it is, before calling upon him for any special breathing. The second is to apply the clip to the sound side, without explaining its purpose, and to let it take action, whilst we examine the pulmonary bases, the heart, and the abdomen. The apical percussion and auscultation are then renewed, and we shall often find considerable changes. Lastly, the clip being still *in situ*, we call for deep breathing and for cough and note the result.

The cases in which the chest-clip is of most signal service are those in which a differentiation has to be made between focal atelectasis, and focal lesions; or between "attitudinal" or "functional scoliotic" inexpansion with dulness, and any genuine lesional inexpansion. It corrects the former and not the latter. These cases are exceedingly common. They are often perplexing, and always cast a serious responsibility upon our diagnosis. That perplexity sometimes gives rise to needless alarm and trouble, and has even occasionally led to a course of sanatorium treatment, which might not have been indispensable.

Finally, as the chest-clip is a delicate test for a latent scoliosis at its earliest stage, and is also its immediate automatic corrective at that stage, it may prove to be the most efficient protection against the progressive development of the deformity, and might save many juvenile patients from permanent damage, or from much irksome later treatment; whilst serving a more vital prophylaxis, that against the risks of pulmonary disease which attach to spinal debility.

VIII.

GENERAL CONCLUSIONS.

THE "THOROUGH APEX TREATMENT" OF CONSUMPTION AND ITS MECHANICAL FACTOR.

Practically the chief danger is not tuberculosis itself but the phthisis pulmonalis which it entails, and which keeps up the supply of its immortal brood. Ever since man first dwelt in prehistoric palaces the bacillus has been at work to immunise the civilised races against its worst infections. Our latest scheme for improving Nature's plan is the proposed extermination of the house fly. Who knows what autumnal scourges we may be inviting thereby? Meanwhile, we are up for exterminating the bacillus. With our eyes open we are rushing back into the peril of the virulent tuberculosis which decimates the still non-immunised, yet "open-air" aborigines with large chests

(*b*) Erratum.—This figure should have appeared on page 195. The figure accidentally substituted for it on that page is there coupled with the wrong legend, which should have read as follows:—"Fig. 1. Smaller pattern for children. The clip is figured in its expanded condition, under stretch of the thickness of the right side of the chest."

(*a*) This simple pattern is supplied at 3s. 6d.

and hearts. Such being our deliberate policy, in its pursuit we might as well be thorough as well as economical. The lung is the breeding-ground, by sole reason of its phthisis. It is wonderfully resistant, except in the phthinoid, to the development of phthisis from simple pure tuberculosis of the apex. But in the phthinoid and others the lung is not strong enough mechanically, in spite of its racial immunisation which suffices in the robust for a spontaneous recovery; neither is their heart. Their phthisis is our enemy. Our first step is to *identify* the phthinoid and the specially predisposed; and the next is to try to add to their inherited or acquired bacillary immunisation the *mechanical cardio-pulmonary immunisation* which they lack. This is mainly a question of school inspection, and of the preventorium. Had we taken those steps a third of a century ago, instead of building first a temple to bacillo-therapy, our present roll of phthisis would have been immensely less than it is, and "the conquest" of the bacillus not a mere *nomen et umbra*.

As regards the apex, the neglect of the mechanical factor has been flagrant "from beginning to end." The worst omission is that of a selective school inspection for the detection of any ascertainable liability, whether merely circumstantial or also structural in addition, which would carry with it the duty of prevention. A suggestion was recently made of a *routine* clinical examination for soundness, and of a certificate of soundness, as the first indication in the systematic prevention of appendicitis (*a*). Phthisis is, however, a vastly more important issue, and a complete return of the "uncertifiable" is urgent in proportion.

In diagnosis, whilst the X-rays contain a growing promise, for which the school might conceivably afford the instrumental opportunity, the success of our old physical examination is dependent upon progressive mechanical improvements, which are often neglected though offered. The chest clip may perhaps get a better chance of usefulness. It is sadly needed for the early detection of preventable apex inexpansion.

The Prone Treatment.—On the one hand, the tuberculin method pure and simple trusts merely to avocational exercise, and makes no special claim to be mechanical. On the other, the sanatorium, apart from tuberculin, is in spirit purely mechanical. Yet in the working how limited its apical methods, which so far as ascertained do not even include the humming cure. As a fact, they do not seem to contain any form of direct apical treatment. In the general scheme of mechanical "pulmonary" treatment, we might have insisted, in referring to the influence of attitude in "lateral" decubitus, upon the still more important and unheeded attitudinal influence of a perpetual "dorsal" decubitus. This was one of the worst faults of the *liege-kur*; in one sense perhaps a *felix culpa*, in that any restriction imposed upon the normal use of the main respiratory reserve favours the activity of the apex if left unhampered, and is equivalent in that particular, like the tight corset in the female, or like strapping down the lung to steady it in early phthisis, to an unintended "local" respiratory apex-treatment in disguise. But, in the continued diurnal dorsal decubitus, that advantage is heavily paid for at the sacrifice of the still more important "general" cardio-respiratory asset. The *prone couch*, conspicuous by its absence at most of our sanatoria, is not open to that reproach. To physiologists and clinicians it needs only to be mentioned to convince them that it cultivates automatically the great pulmonary reserve, which is the posterior base; and that it does so by posterior costal rather than by phrenic work. They will perceive that in the "thigh-elbow procumbency" it mobilises the entire vertebro-costal mechanism; and that, by virtue of the clavicular immobilisation, is mobilises the upper dorsal section of it much more effectually than any other exercise, with the sole exception of unilateral breathing. This orthopædic principle has only recently been recognised by F. Kirchberg (*b*), R. Mesnard (*c*), F. Göppert (*d*), and H. Spitzy (*e*).

The other, or *abdominal* aspect of the prone treatment is not yet realised, except experimentally in Schepelmann's remarkable *visceral compression* (*f*) of the lung by ablation or paralysis of one wing of the diaphragm, as a substitute for pneumothorax compression. And yet it had been provided for, some years ago in the many-sided "Convalescent Machine" (*g*) for spinal re-education after prolonged recumbency; and before then in the "Infant Rest" and the "All Fours Exerciser" (*h*), as the most essential part of the "thorough treatment" of rickets, in which the leading abdominal factor is also attended to mechanically during the early recumbent stage, by means of Rose's elastic belt. In this case it is not only that the apex has to be developed whilst the spine is being strengthened and protected from scoliosis by relieving it of the weight of the head, but that the entire thoracic costo-chondral inversion has to be prevented, straightened-up, and splinted-up by a steady, upward internal visceral pressure, analogous to Schepelmann's. This is also my late corrective method for the neglected cosmetic treatment of the pigeon-breast deformity brought about by the continued neglect of the obvious mechanical indication during the active stage of Rachitis. Inshort, the prone couch provides not only the most abundantly ventilating apex-treatment, but a *posterior apex-treatment* specially addressed to the larger and stagnant "niched" section of the apex, which is the special object of our prophylaxis, and the seat of election for the earliest bacillary settlement.

The Inclined Prone Couch.—This late refinement in the mechanical treatment of excavating phthisis, which we owe to Tucker Wise, of Montreux (*i*), is not yet usually included in the sanatorial furniture, although cheap and easily procurable. The special suitability of the inclined plane for that stage had not been insisted upon by Quincke, although Piorry long ago had suggested it in his remarks on "l'expectoration provoqueé," nor by myself when introducing its continuous use for recumbent bronchiectasis, and its intermittent diurnal use by means of the Convalescent Machine or of the All Fours Exerciser. Tucker Wise's inclined wicker couch carries out in a definite degree the abdominal method suggested in Schepelmann's experiments. It is therefore worth considering as a systematic apex treatment. It has, however, been chiefly recommended by its author as a mechanical bronchial treatment, and for short instalments only. There is no doubt that in that form it is harmless as well as convenient, as the most efficient evacuant for the catarrh which inevitably spreads down the large posterior bronchial distribution as a result of a continuous dorsal decubitus, and more or less also of the long nocturnal recumbency in all cases of phthisis catarrh.

In conclusion it is hoped that a sufficient plea has been made out for a more thorough treatment of consumption. At all points the mechanical factor is the chief blank and the greatest need. In prevention, thoroughness is wanted in the identification and registration of the personal structural liability, as the most efficient notification can only deal with the circumstantial and familial liability. And it is also wanted in the shape of direct preventive apex-culture. In diagnosis the mechanical factor is capable of much more than has hitherto been attained with too little help from it. In treatment, at all stages, it is paramount for local, as well as for general or vital therapeutics. But the stage for its urgent use and for its greatest possibilities is the neglected early stage.

To sum up in a few lines this long argument : The mechanical aspect is the larger part of the bacillary question. The importation of the bacillus is mechanical, its exportation is equally mechanical. Those are the essential considerations. *"Immunisons"!* Tuberculin by all means for the blood, as an immuniser and perhaps as a hormone. But in the lung let us make straight for the bacillus. Let us turn it out if we can by the lymph and air-pump. This may also best help us to lock it up quickly and permanently in its closed stage when there is still no way out for it.

SOME UNUSUAL CASES OF HYDATID DISEASE.

By HENRY M. O'HARA, F.R.C.S.I.,
Melbourne.

In the whole range of surgical phenomena there is nothing more erratic in the choice of its locale than the echino-coccus.

Looking through my notes for the past thirty years I have picked out from several hundred cases a few that I think are worth reporting, as each case presented some difficulty in diagnosis—In fact, the majority not being diagnosed until an exploratory operation had cleared up the condition.

Hydatid disease is not nearly so prevalent in Victoria to-day as it was thirty years ago. I attribute this to the greater care now bestowed upon the storage of drinking water, which was undoubtedly the chief carrier of the ova in former days ; dogs having free access to the domestic water-supply, which, in the country, was drawn from the nearest creek or river, but in most cases now the rain water for drinking purposes is conserved in iron tanks.

A number of different methods of attacking a hydatid cyst surgically have been advocated, but Lindemann's operation has held its own in this country and is still the one of choice. In many cases one is tempted to explore with a needle the contents of these fluctuating tumours, but I have laid it down as a hard-and-fast rule never to attempt any needle exploration unless I have everything prepared to complete the operation for the evacuation of the contents.

Case I.—Hydatid at the Back of the Eyeball.

In 1885, Dr. Mannington Caffyn asked me to see a young lady whom he had been attending for neuralgic pain in the left eyeball and diplopia. The pain had become intense, and it had lately been noticed that the eyeball protruded slightly more than the opposite eye.

On examining her I found marked proptosis of the left eyeball, painful on pressure. The vision was not affected except that she complained of double vision at times. The eyeball was fixed somewhat and could not be rotated outwards, and I thought on palpation that I could detect some fluctuation between the eyeball and the orbital plate. I suggested exploring this space with a hypodermic syringe, and I withdrew a syringe full of clear fluid, which, on examination, proved to be hydatid. I then opened up the space and removed the mother-cyst ; it was a sterile hydatid. The pain ceased immediately and the eyeball resumed its normal position.

The patient made a good recovery.

Case II.—Hydatid on the Brain.

In the Inter-Colonial *Quarterly Journal of Medicine and Surgery*, of May, 1894, the notes of a case that I showed at the monthly meeting of the Victorian branch of the British Medical Association were reported. The patient shown was a boy from whose brain I had previously removed a hydatid cyst.

On September 21st, 1890, I saw the patient for the first time. He had been sent to me by Dr. Tremearne, of Creswick, and I elicited the following history from his mother :—

"H. M., æt. 6, residing with his parents at Woodlands Station, Ararat, Victoria. He had been a healthy child until the age of 5 years, when he was suddenly attacked with severe pain on the left side of the head, accompanied by vomiting and giddiness. The pain being persistent medical advice was sought, and he was treated for migraine. He did not benefit by the treatment and was losing flesh rapidly. In September, 1889, he had a fit which lasted for two hours, and on coming round it was discovered he was paralysed down the right side, right leg and arm, and was quite blind. He had marked twitchings in the left cheek and at the angle of the mouth, and was deaf on the left side. This condition continued for nearly three weeks when the sight returned and the leg partially regained its power. After the lapse of another ten days the arm began to improve and he could use it a little. The left side of the head was now noticed to be a little larger than the right, but his general condition began to improve. The pressure was evidently relieved by slight yielding of the bone. The headache persisted and was worse at night. He spent most of his time lying down with his head resting on a large hot foment, which seemed to give him some relief. Family history was good, and his father and mother were in excellent health. He had constantly drunk water from the river which ran close to the house, and dogs and other animals were in the habit of drinking from the same source."

On examination, I found a slight prominence of the left parietal region with well-marked œdema of the scalp over that locality, painful on pressure ; double optical neuritis, more advanced in the left eye ; he was quite deaf on the left side ; there was slight aphasia ; loss of power in the right hand and forearm, but sensation was perfect ; and slight twitching at the left angle of the mouth. All his other functions were normal, pulse regular ; urine, specific gravity 1018 acid, no albumen ; temperature normal.

The symptoms of cortical pressure over the arm, leg, and speech centre were sufficiently well marked to warrant my advising an immediate exploratory operation, and having impressed upon the mother the urgency of the case she reluctantly consented to my proposal.

I called Dr. James Cox into consultation, and he having endorsed my diagnosis, I proceeded to operate. The boy having been chloroformed and thoroughly cleansed, following the line laid down by Lucas Championnière for exposing the fissure of Rolando, I made a V-shaped incision through the soft parts down to the bone; this took in the anterior third of the left parietal bone and a small piece of the temporal bone. I next applied a Hey's saw, and having cut through the bone turned up a triangle with the soft parts attached. On lifting the bone the dura mater bulged through the opening, a fine cannula was inserted, and some hydatid fluid flowed through. I now laid the cavity open and evacuated about six ounces of hydatid fluid containing numberless daughter-cysts. The mother-cyst was withdrawn and the cavity well washed out with boiled water.

At this stage the condition of the patient was most alarming, but Dr. Cox administered a hypodermic injection of ether and he rallied.

The hydatid was originally meningeal, and growing larger encroached into the brain matter.

I replaced the triangular piece of bone, merely cutting off a small piece at the apex of the triangle to admit of a drainage tube. The cavity was about the size of a hen's egg. This was irrigated daily. During this time I invited several surgeons and physicians to see him.

He made an uninterrupted recovery. I saw this young man recently. He is now working on a sheep station, and is in every respect a healthy man.

Case III.—Hydatid of the Left Lung Implicating the Pericardium.

Mr. H. was sent to me on June 20th, 1901, in consultation with Dr. A. V. M. Anderson. He had been losing flesh gradually for several months. He complained of cough and a pain in the front of his left chest. A fortnight ago an ounce or two of perfectly clear fluid came up into his mouth, there were no skins in it. Since then he had had expectoration of muco-purulent matter, which had been examined microscopically but no tubercle or hooklets had been found. He had no night sweats and the temperature had never risen above 99.

On examination, we discovered a dulness just below the left spex continuous with the normal cardiac dulness, going up as far as the second left space, two inches from the left border of the sternum. There were indistinct cracked pot sounds over this area, and some crackles at the end of inspiration. The heart was not displaced.

On June 27th, 1901, the dulness was more extensive and reached to the nipple line in the second left space. A needle was inserted into the second space and pus withdrawn.

I admitted him into my private hospital, and on July 4th, 1901, Dr. Anderson administering chloroform, I removed a piece of the second, third, and fourth ribs. The space around this was now carefully packed with gauze and an incision made into the cavity. The edges of the cyst wall were sewn to the chest, and the cyst opened and evacuated. The pericardium was now seen to form the posterior wall of the fibrous capsule, and moved with the cardiac pulsation. The cavity was drained.

The patient made a rapid recovery. I saw him quite recently when he expressed himself as feeling quite well.

Case IV.—Spontaneous Fracture of the Humerus caused by Hydatid Cyst in the Shaft of that Bone.

In 1889, Dr. Verity of Cheltenham, asked me to see a case of spontaneous fracture of the humerus in its upper third. The patient, L. H., æt. 20, the son of a market gardener, was driving a cow home, and when throwing a stick at it he felt his arm give away and become helpless and very painful. He had suffered from some pain and thickening in the arm previous to this, and had had it rubbed with a liniment thinking that it was rheumatic. Dr. Verity applied a rectangular splint and kept the arm at rest for ten days before I saw it. His reason for calling a consultation was on account of a fluctuating swelling which persisted in the upper half of the humerus at the side of the fracture.

My first impression on examining this was that it was a case probably of sarcoma of the bone as the contour was very like that condition, but the fluctuation was so unusual that I suggested exploring it.

Under strict antiseptic precautions, under an anæsthetic, I made an incision into the swelling and this was followed by a gush of hydatid fluid with numberless small hydatid cysts. The hydatid contents were thoroughly cleared out, some spicules of bone were removed, and the arm was put into a plaster-of-Paris splint with a window.

The after-treatment of this case was very tedious as pieces of bone kept coming away and union did not take place.

Three months afterwards I re-opened the wound and thoroughly removed all *debris*, and freshened up the fracture, the ends of which had not united, and the arm was again put up into a plaster-of-Paris splint. Union of the bone now took place, and six months after the original fracture he could use the arm, but there was some stiffness at the elbow joint from fibrous adhesions.

In this case, our first opinion being more pronounced in favour of sarcoma, had the fluctuation not been so evident amputation at the shoulder joint would certainly have been advised. It impresses one more than ever of the value of an exploratory incision in every case where there is the remotest doubt.

Case V.—Hydatid in the Jawbone Simulating Actinomycosis.

In 1895, Dr. Sparrow, of South Melbourne, asked me to see a swelling in the ramus of the right lower jaw of a man who had been working upon the wharf at Port Melbourne. The appearance of the jaw was very suggestive of actinomycosis. He had wasted considerably and there was a good deal of pain. Previous to his work on the wharf he had been attending to cattle in Gippsland, where lumpy jaw in the cattle was prevalent, and where some cases of actinomycosis in human beings had been reported.

On making an incision into the tumor hydatid fluid escaped. The contents of the cyst were thoroughly evacuated, the wound was packed, and he made an uninterrupted recovery.

Case VI.—Hydatid in the Apex of the Right Pleura Simulating Aneurysm of Innominate Artery.

This was the case of a man, æt. 40, who applied for admission to one of my beds in the Alfred Hospital. There was well marked bruit over the tumor, and after consultation it was decided to tie the subclavian artery in its third stage. This I did and he seemed to improve for some days, but an attack of pneumonia supervened and the patient died.

The *post-mortem* examination revealed a hydatid cyst about the size of a bantam's egg pressing upon the innominate artery.

Case VII.—Hydatid in the Posterior Surface of the Liver Pressing on the Head of the Pancreas, Simulating Disease of that Gland.

Mrs. F. L., æt. 30, married, came under my care at the Alfred Hospital during 1912. She gave the following history:—

"She had been in the Alfred Hospital in 1910 where an exploratory operation had been performed by my colleague, Mr. Hamilton Mussell. He opened the abdomen over the region of the gall bladder and a tumor was found on the anterior surface of the liver, not extending down to the edge of the liver. A needle was introduced and altered bile withdrawn. After needling in several directions clear fluid like hydatid fluid was found in small quantities, but nothing further was done. It was thought that there was a small hydatid in the centre of the liver, but no attempt at removal was made (the records in the Hospital's casebook do not say why), and the abdomen was closed."

When the patient came under my care she complained of intense pain increased on pressure (which had been constant since last operation), loss of flesh, and quite unable to attend to her duties.

On August 2nd, I reopened the abdomen in the line of the old incision and exposed the liver. Adopting the method suggested by Mr. Mayo Robson, the liver was grasped, pulled down, turned over, and the posterior wall exposed. A hydatid cyst about the size of a golf ball, undergoing calcification, was found. This was opened, several daughter-cysts were evacuated, and the mother-cyst removed. The cavity was washed out and packed with iodoform gauze.

The patient made a slow recovery and was discharged from the hospital with a sinus still communicating with the cyst cavity.

As I had resigned my connection with the Alfred Hospital, my successor, Dr. R. C. Brown, subsequently dilated the sinus and allowed a quantity of pent up *debris* to escape. The cavity was irrigated, and the patient made a good recovery.

I attribute the pain in this particular case to pressure upon the head of the pancreas and its duct, as the calcifying mass was very hard and occupied a part of the liver overlying that organ.

Case VIII.—Hydatid at the Base of the Lung Causing Laryngitis.

Mr. S. was being attended by Mr. Iredell for chronic laryngitis. The symptoms of inflammatory changes in the larynx were very marked, the cough was persistent, and the voice typical of the condition.

On examination of his chest, I discovered a small crepitant patch at the base of the left lung. Dr. A. V. Anderson endorsed this. I explored with a needle and found pus under A.C.E. I resected a portion of the rib and evacuated contents, and drained cavity.

The patient made a rapid recovery and the laryngeal symptoms disappeared.

Since the discovery of the X-rays it is now an easy matter to locate pulmonary hydatid cysts, the shadow outline shows out so clearly in the lung tissue. I feel sure that in the pre-Röntgen days very many cases of pulmonary hydatid were overlooked altogether and many others diagnosed as tubercular disease, only to be discovered at an autopsy or when the more fortunate occurrence of rupture into a bronchus enabled the patient to present the often perplexed physician with a specimen of his trouble in the form of a daughter-cyst.

OBSERVATIONS UPON SOME OF THE DISEASES WHICH ARE COMMUNICABLE FROM ANIMALS TO MAN. (*a*)

By FREDERICK HOBDAY, F.R.C.V.S., F.R.S.E.
Honorary Veterinary Surgeon to His Majesty the King; and formerly Professor in the Royal Veterinary College, London.

When I was honoured by a request to read a paper before your Society I selected the subject of "Some of the Diseases Communicable from Animals to Man," and of these, so far as our knowledge takes us at the present time, the list includes, for certain, tuberculosis, anthrax, glanders, rabies, vaccinia, mange, ringworm, measles in cattle and the *Tænia medio-cannelata*, measles in pork and the *Tænia solium*, echinococcus and trichinosis, foot and mouth disease, Malta fever, plague and sleeping sickness; whilst tetanus, actinomycosis and a number of others can be produced with equal facility in man and animals by inoculation with the same causal organism.

Truly a formidable list, and one to which others will undoubtedly be added as our knowledge increases, and one which shows the importance of a complete understanding between the members of the medical and veterinary professions to work together against the common enemy—disease. This is well illustrated when one considers the question of the diseases which are intercommunicable between our respective patients, and especially is the case in a country like ours where the people are so constituted that an affection for animals, and the desire to possess a pet of one or other species, is ingrained from childhood, extending from the kitten or rabbit of the child who can scarcely walk to the schoolboy's pony or the lady's pet dog.

All of them possess the power of becoming infected with diseases, which they can transmit to their owners either direct or by acting the part of the intermediary host.

It is to some of those of which we have certain knowledge which I propose to draw your attention to-night, as to include those in addition upon which mere suspicion alone falls would make the list so long that we should never get beyond the fringe of it, and as I am addressing an audience of London practitioners I will confine myself to the four which are most likely to be met with here, and of each of which I have had personal experience of their trasmission from animals to man.

The four I have selected are: Glanders, tuberculosis, mange and ringworm.

Glanders.

Glanders is, as you know, a disease especially seen in horses, and in London it used to be the one which was the most dreaded of all by the owner. It is scheduled under the Contagious Diseases of Animals Act, and comes under the jurisdiction of the London County Council, who have three veterinary inspectors doing nothing else but inspection work and not engaged in private practice.

Until about ten years ago it was done by certain private practitioners, and in many districts it was a

---

(*a*) A paper read before the West London Medico-Chirurgical Society, May 2nd, 1913.

most unusual thing for a day to pass without several fresh glanders cases being reported to them.

This district was a fair hotbed, and the cab or omnibus stables of Hammersmith, Fulham, and Notting Hill were always more or less in a state of infection.

This was due in part to the inefficient state of the law, which only permitted the veterinary inspector to interfere with the clinically glandered cases and not to enforce the mallein test.

Often and often have I, as inspector, been called into the stable of a cabman or contractor where a visibly glandered horse was present, and beyond ordering its destruction, have been powerless to do anything to find out whether the others were healthy or not. I had the power to inspect their exteriors but nothing further, as I could not carry out the mallein test without the consent of the owner—and very few owners would consent to this. Where the mallein test could be applied it sometimes meant the destruction of 10, 15, or even 20 per cent. of the horses in the stable, and at the very least it usually meant the horse stabled on either side of the visibly infected one.

Now, however, when an outbreak occurs in a stable the test is applied and all reactors are valued and slaughtered.

In former years the owner, if he was a cunning man, dispersed his stud and sold them at the next repository sale, or, at all events, sold any suspicious ones, thus disseminating the disease far and wide amongst his neighbours, and, in regard to man, it was principally amongst the strappers and grooms who worked in stables of this class that the disease was met with.

Although not a common disease in man, it used to be sufficiently often met with in London, Glasgow, Liverpool and other large cities to make it of interest to the medical man, who did not, however, always diagnose its presence until after, or just before, death. I well recollect how this fact was impressed upon me, because in neither of two cases in man which I have seen here in Fulham, and at whose *post mortems* I was present, was the diagnosis made until near death, although, of course, the result would in any case have been the same. Cabmen and stablemen in London know well of its contagious nature, and the names of "glanders" and "farcy" are familiar to every one of them. A horse with a persistent nasal discharge is always a source of suspicion, and if there is an enlarged sub-maxillary gland the suspicion may be strengthened and the case should be professionally examined. In connection with the discharge, and the enlarged gland too, it is a point worthy of note that if only one is affected it is invariably the left one.

Careful examination of the interior of the nostril, especially the septum nasi, may reveal the presence of ulcers, in which case the diagnosis may be confirmed at once, or it may be merely congested—a further sign of suspicion.

In any case the mallein test should be applied and the matter settled once and for all.

With this agent, the discovery of the Russian scientists Helman and Kalning, the animal is hypodermically injected in the neck (or some place where the skin is loose and where the harness does not touch), and if glandered (whether slightly or not) the temperature rises steadily, an average of from two to five degrees, within the next twenty-four hours; and, in addition, a diffuse swelling rises up about as large as the palm of a man's hand, painful to the touch, and extending on the second and third days usually in a downward direction towards the lymphatics of the shoulder. If the animal is kept alive this gradually subsides, but can be readily demonstrated again in about three weeks by a further injection.

The ophthalmic mallein test is also used, as are also the serum diagnosis and agglutination tests.

Other clinical signs on the body of the horse are the presence of swellings, usually along the course of the lymphatics of the neck or inside the thigh, termed "farcy buds," which suppurate and burst, the discharge from them being highly dangerous and infective.

It is from these that brushes, sponges, and stable utensils are apt to convey the disease from horse to horse, and from these, as well as the nasal discharge, that man becomes infected.

Of its prevalence in London you may have some idea when I tell you that in 1901 there were reported 2,370 cases in Great Britain, of which 1,828 came from London, 67 per cent. of which were from permanently infected stables (Hunting). In 1908 there were 789 outbreaks, of which 495 were in London, and 198 in the Metropolitan counties, whilst 2,433 horses were killed on acount of the disease. Last year the numbers had been reduced to only 504 individual horses for the whole of Great Britain, and it is safe to prophesy that, with the advance of the motor, in a few more years glanders will be non-existent.

Of the symptoms and course of the disease in man it is not for me to speak, but the absence of definite and differentiating symptoms makes it necessary to be borne in mind when treating stable hands, and makes inquiry necessary.

In each of the cases I saw the men had had symptoms like those of a chill, accompanied by severe muscular and articular pains; in one case the man had been ailing off and on for ten months, and his lungs were full of glanders nodules.

Of other animals, the only one the veterinary surgeon need pay especial attention to are those confined in zoological gardens and such-like places, especially lions and tigers and those of the cat tribe. Occasionally epidemics of glanders have broken out in them as the result of eating infected horse-flesh, and the effects have been disastrous.

Tuberculosis.

At the present time the question of how to efficiently deal with this disease is occupying the minds of all classes, and the new Order of the Board of Agriculture and Fisheries, which became law yesterday, will start a new crusade against this terrible disease in cattle, and through them, we hope, help to stamp it out in man.

All the domesticated animals, and even birds, are fair play for the tubercle bacillus, although some animals are more susceptible than others, and no organ of the body is exempted from its ravages. The question of heredity plays a very small and inconsiderable part when compared with that of exposure to the actual contagion, and the work of Bang in Denmark has demonstrated clearly that the offspring of tuberculous cows remain healthy and free from tuberculosis if properly guarded against infection after birth.

In the horse, dog and cat the disease is well recognised, and with the latter two this fact must be kept well in mind, on account of their constant presence in the house as pets; but it is with the cow and her supply of household milk that the chief source of danger arises, and a few extracts from the new "Tuberculosis Order" of 1913 will not be out of place.

In regard to the notification of the disease, the new Order of the Board of Agriculture and Fisheries, which came into force only yesterday, enforces compulsory notification to the police (or to an inspector of the local authority) of any cow which is, or appears to be, suffering from "tuberculosis of the udder, indurated udder, or other chronic disease of the udder," or from "tuberculosis with emaciation."

This notification has to be made by the owner and also by any veterinary practitioner who has knowledge of any of the above.

The veterinary inspector of the local authority then received instructions to inspect the animal and any others on the premises, and, with the consent of the owner (not otherwise), he may also use the tuberculin test on any other suspected beast. The inspector may enter the premises at all reasonable hours, and take samples of milk, of urine, fæces, or any abnormal discharge, and where satisfied that tuberculosis exists (either generally or only locally in the udder), a notice must be given in writing to the owner and also to the Board of Agriculture, and the animal shall be slaughtered. The carcase of every animal thus slaughtered is to be subjected to *post-mortem* examination, and a fair compensation given, this being based upon a valuation made upon the animal during life, and subjected to certain corrections if the *post-mortem* examination does not bear out the diagnosis.

The Act deals with the sterilisation or destruction of milk from any chemically diseased udder, and the utensils used to contain such milk, and also with the isolation of any beast which is under suspicion. Fairs and sale-yards are also brought in as "places" under the Act, and the veterinary inspector is required to use his authority here as well as in farm byres and cowsheds.

Owners and veterinary surgeons who fail to give notice of suspected cases are deemed guilty of an offence under the Act, and any failure to comply with the orders of the veterinary inspector is dealt with by the infliction of certain penalties.

The carrying out of this Act is one of the biggest and most responsible positions which have ever been entrusted to the veterinary profession, and it will rest with us to show that the trust has not been misplaced.

Once get the milk question settled and tuberculosis of cattle completely eradicated and we shall indeed have done something to have helped you of human medicine in your fight against disease.

When one considers that the statistics show that the human death-rate in England and Wales in 1910 was 51,317 from tuberculosis alone, and every year approximates this, it is not to be wondered at that every way of possible infection must be got at and stopped at its source. Hence the tuberculous milk question plays no small part in the game.

According to Prof. Delepine, of Victoria University, there are over a million and a half tuberculous cattle in Great Britain, and scarcely any investigator puts it down at less than 25 per cent. of the milking herds, whilst Mr. Brittlebank, the Chief Veterinary Inspector for Manchester, estimates the annual loss to dairy farmers in England at nearly one million pounds.

In other countries the same prevails, and in every country the toll exacted is enormous. A bacteriological examination made in 1908 of milk in certain of our biggest cities, including London, Liverpool and Manchester, has demonstrated that tubercle bacilli were detected in one city in 10 per cent. of the samples examined, whilst in Liverpool, owing to the better veterinary inspection of the cattle and farms supplying the city, the percentage was only 3 per cent., and in 1911 this was still further reduced to 1 per cent. The latter, however, is far too great, and although the efficient control of the source of the milk supply of a large city like London is very difficult, it is to be hoped that the new Order, just in force, will make it *nil*.

We can only work, and "wait and see."

MANGE.

Every species of domesticated and many wild animals may become the subject of an attack of mange, always caused by the presence of a parasite, always caught from somewhere, and always contagious to man as well as to other animals. In this instance, as in many others, the parasite does not of necessity find its new host, when transmitted to man, as comfortable and convenient a resting-place as its original host, and as a rule it lives its life but does not propagate.

It is a common and well-known disease of the horse, cow, dog, cat, pig, and camel; foxes, ferrets, and other semi-wild animals; lions, tigers, and most wild animals; besides rabbits, monkeys, and such-like children's pets; and from every variety of animal it is transmissible to man, if only the conditions become favourable.

In the horse we recognise three varieties, and two of them are now scheduled under the Contagious Diseases of Animals Act, and must be reported to the authorities, who deal with them through a veterinary inspector. The different varieties are the sarcoptic, the psoroptic or dermatodectic, and the symbiotic.

The two former, in particular, are transmissible to man, and a certain amount of care is always to be exercised by the attendants who dress the patients, and by slaughtermen and knackers who have to deal with the carcases. Once the diagnosis is established the treatment is generally efficacious, although sometimes prolonged and troublesome. For animals an oily dressing is always the best, and sulphur forms the chief ingredient of most external safe dressings Oil of tar, paraffin, creolin, creosote, and turpentine are all used as adjuncts to oil and sulphur, but their proportion must be adjudicated with discretion, as all are more or less irritating, and the skin of all animals is extremely absorbent.

In the dog, cat and smaller animals we have to use exceeding care, as many cases of poisoning have occurred, owing to their peculiar idiosyncrasy towards certain drugs. For example, it is better not to make use of any preparation containing carbolic or cresylic acid for these animals, and even in a big beast, like a horse, they cannot be used with impunity. Creolin, in all its many advertised forms (although at one time stated to be "absolutely non-poisonous"), and preparations containing mercury, should never be used except under skilled advice, either as a watery or an oily dressing; and to any furry animal like a cat or rabbit the constant use of baths or watery dressings is sure to give a high percentage of fatalities.

Such are some of the difficulties which beset the path of a veterinary surgeon, whose patients vary so greatly in size and temperament, and I touch upon them briefly to show that we have much in common with our medical *confrères*.

Dog and Cat.—That mange in the dog and cat may be transmitted to human beings is a very important fact to bear in mind, and quite recently Dr. Whitfield, the Dermatologist at the Great Northern Hospital, and myself have published in the *Veterinary Journal* (and it was commented on in the *Lancet*) some seventeen authenticated cases in which the disease was transmitted from dogs or cats to their owners, he being responsible for the diagnosis in the human, and I in the animal. I particularly draw attention to this because in none of our cases of the affection in the skin of the owner had any serious thought been given either by the medical practitioner or the owner to the dog or cat, and the disease had been treated unsuccessfully, either as pruritus or eczema. Generally the subjects are women or children, whose affectionate dispositions lean towards the persistent nursing of the dog, some even going to the length of allowing the animal to sleep in the bed—a practice much to be objected to.

The usual site of the disease was either on the upper surface of the arms or around the neck, the infection to the latter place being acquired by the persistent cuddling of the dog, and the former by allowing the animal on the lap, in which situation a dog is continually fondled and stroked, and often develops a habit of resting its head upon the wrist or arm. It is when the arm becomes warm that the transfer of the parasite takes place.

The following is a description by Dr. Whitfield and myself in the *Veterinary Journal* of November, 1912:—

"The symptoms in the human being are shortly as follows:—No part of the body other than the hairy scalp remains unaffected, the whole of the trunk, arms, legs and face being attacked. The eruption called forth by the parasite is essentially vesicular in type. The individual lesion is a very small and rather thin-walled vesicle, rather smaller than the ordinary eczema vesicle and surrounded by a narrow zone of hyperæmia; in fact, the primitive lesion may be described are very like that of varicella, but of only about one-eighth the size. These lesions are always scattered discretely over the surface, and in no case have we seen any grouped or aggregated lesions. The scratching of the patient—for the rash is intensely pruritic—leads to the decapitation of the little vesicles, and their original site then becomes covered with either a serous or a blood-scab. No burrows are found, and hence it is extremely difficult to find the actual parasite. In no instance has this been found in the human subject in our list of cases, though one of us searched with a lens and a pin for two hours in one case.

"In the last case which we saw together the animals spreading the contagion were cats, and the disease in them was not very typical, but the transmitted disease in the human being was sufficiently characteristic to lead to a diagnosis in the cats, and this was confirmed by demonstrating the acarus miscroscopically in a crust taken from one of the cats.

"Nevertheless, owing to the fact that we are unable to find the acarus in the human, it is probably not possible to assert positively that the eruption is due to sarcoptic mange, unless one can confirm the suspicion by the fact that the person has been in contact with an infected animal. Still, for some years now we have not made an error as far as we know, and in all the five cases seen by only one of us the appearance of the rash led at once to the question as to whether the patient had been in contact with a mangy animal.

"The course of the disease in the human being is said to be about six weeks in the absence of treatment, but naturally we have not left a case untreated when once diagnosed. The ordinary treatment for human scabies is quite efficient, and the disease shows less tendency to relapse, probably because the acarus does not form burrows. One rather important point we may note—namely, that in one of the five patients' cases the patient had had the disease three times running at short intervals because his doctor had treated him for scabies and had not inquired about his dog, which was supposed to have 'eczema,' and this, of course, is quite likely to occur if people are not on their guard."

Its presence in man is manifested by a troublesome irritation and papular eruption, with small black spots quite visible at the places where the heads have been removed by scratching.

Mange in the dog and cat is a very common disease indeed, especially in London and large towns where many of these animals are kept.

In the cat is is due to the presence of a sarcopt and principally affects the head and neck first, spreading to the rest of the body chiefly through the agency of the hind limbs, which are used to do the scratching, and a badly affected cat, if not treated, eventually develops into a sorry-looking beast, the head being covered with scabs and scales from which the parasite can be demonstrated microscopically with the greatest ease. In the dog we have two varieties—the sarcoptic and the demodectic—the former due to a parasite of the usual itch variety, the *Sarcoptis canis*, and the latter to the *Demodex folliculorum*. Each has its analogy in the human species, and both are contagious to man, the former especially so.

The *Demodex folliculorum* takes on a most virulent form in the dog, and an animal bady affected loses all its hair, has a very offensive smell, and finally becomes a very loathsome object. Its cure is always a matter of difficulty and is often impossible.

In sarcoptic mange the dog is persistently scratching, especially under the arms and thighs, and when in front of the fire or in a warm room cannot keep still. If neglected the coat falls off, the skin becomes covered with blood-stained scabs, and there is a peculiar "mousey" odour.

I mention these symptoms in more detail to-night because of drawing particular attention to the transmission of the sarcoptic parasite from the dog or cat to owners of these pets; for I feel sure, from what I have observed, that although the fact may be known, it is not suspected as often as it ought to be, and infections and re-infections are common from this source.

Ringworm.

Another common illustration of a skin disease transmitted from animals to man occurs in the case of the various varieties of ringworm of the horse, calf, and dog and cat in particular. Those particularly met with are the ordinary ringworm (tinea tonsurans) and the honeycomb ringworm (tinea favosa).

The former infects all animals, but is of the most importance to us to-night because of its prevalence in horses, dogs and calves. In London we meet with it in the two former animals, and in country districts the ringworm of calves is a common disease. All are contagious to man, and, in so far as animals are concerned, are tolerably easy to cure, the best remedies being either the tincture of iodine or the alcoholic solution of salicylic acid. They require, however, considerable care and thoroughness in application.

I have had personal experiences of its communicability to man from the horse, the calf and the kitten.

ARE MICRO-ORGANISMS THE DEMONS OF THE ANCIENTS?

By JOHN HY. ALEXANDER, M.B., C.M.,

Edinburgh.

Having not long ago read a book entitled "Demonic Possession," by W. Menzies Alexander, I was amazed to find that amongst some very absurd ideas held by the ancients about demons, especially by the Jewish Rabbis, much may be found which would seem in a great measure to anticipate modern science. I am giving in this paper a few extracts about their beliefs, and I hope to show that many attributes of these demons of the imagination are characteristic of what we might call "modern demons." These imaginary demons seemed so real to the ancients that they became a veritable source of terror to the human race, and are so still among uncivilised races. The devils, demons, or agents of Satan (call them by any of these names) of to-day are not only objects of fear, but are really foes (at least many of them are) to mankind. Their presence is either inferred from the effects they produce on living beings, or is shown by ocular demonstration. They live not only in the blood and secretions, but in many tissues and organs of animals and men.

As the ancients imputed most of the ills of life to the influence of immaterial and unseen demons, so do we to-day attribute, if not all, at least the greater part of our ill-health and diseases to the presence in our bodies of what scientific men call micro-organisms. Like the ancients, uncivilised races to-day try, by means it may be of human sacrifices or the offering of paper money and sham rice, as do the Chinese, to conciliate the demons and render them favourably disposed towards mankind. It must not be thought that all the demons were injurious; many, on the other hand, were regarded as good, and were looked upon as harmless or even helpful to the human race.

Demons are mentioned in the Old and New Testaments (Revised Versions) and in the books of the Apocrypha. The early Fathers of the Church:—Justin Martyr, Tertullian, Origen, etc., believed in their existence.

Justin said that demons sow murder, war and all wickedness. Tertullian said that demons produce illness and physical calamities with sudden fits of madness, and, being invisible, their actions are only known by their effects and they enter the blood of animals—wolves, foxes, weasels, birds, and serpents; they also cause plagues, famine, pestilences, and blight of fruit trees.

The Babylonians believed that demons swarmed everywhere, that there was no nook or corner in existence but was filled with them, and they were specially associated with impure places and those of burial. The inhalation or swallowing of stray demons was the cause of disease. The demons were sometimes obliged to contend with dogs over offal. To combat them the great thing was fire, and so they (the Babylonians) put their trust in Gilpil, the god of fire.

The Arabs are said to so thickly people the desert with demons that they apologise when they throw anything away lest they should strike a demon unwittingly. They believe that demons haunt the baths, wells, ovens, ruined houses, market places, and burial grounds.

The Fijians believe they are constantly exhaling and spitting out demons. In China the aid of demons is resorted to for the cure of disease, and by charms and sacrifices they are propitiated.

In his book Professor Alexander says that the doctrine of demons was most highly developed by the Jewish Rabbis; they even had an eye salve which, when rubbed over the eyes enabled one to see the demons, and so brought home the truth of the doctrine to the most sceptical person. They believed that demons, being male and female, propagated their kind, and they said were we permitted to see the malignant spirits which beset us we could not rest on account of them: there would be ten thousand on the right hand and one thousand on the left. Those associated with dirty places were black in colour, while others were blind. He goes on to say that it was believed that demons surrounded men as earthed up soil in garden beds, they were found on unwashen hands. Graveyards were their favourite resorts. Ruined baths were their beloved haunts. The desert was their special home. They might be connected with certain animals as the mad dog, the fly of Egypt, the wasp of Nineveh, the scorpion of Hadabiah, and the serpent of the land of Israel. The night traveller had to brave great perils on account of them. The Lilen were specially dangerous to children who ventured out of the house during the hours of darkness. Under cover of darkness demons surrounded the house and injured those who fell into their hands. Further on in his book, Prof. Alexander says, "The risk of going out to unclean places was very great. Shabrivi was always a menace to those who drank water by night. Chamoth, the demon of oil, caused eruptions on the face. Cardicus, a demon who ruled over wine-bibbers, caused headache. Bath-Chovin was a demon of sickness. Disease in general was caused by demons. Sick women as well as brides, bridegrooms, mourners, and the pupils of the Rabbis were specially obnoxious to the demon of darkness. To demons were ascribed leprosy, rabies, croup, asthma, cardiac disease, epilepsy, melancholy, bodily distortions, mental distractions, and infantile convulsions. They required sustenance, and this they found in certain essences or in the elements of fire and water. Wine was a great abomination to them as well as pungent odours or loathsome smells. The loss of the divine image had rendered man subject to those agents of destruction. Originally he was immune from such attacks. Ablutions, phylacteries, and washing of hands were all protective as well as torchlight. Covenant salt eaten at meals had defensive virtue, so had the application of rouge to the eyes. Circumcision was held in much esteem."

The modern Parsee believes that round the darkhmas, where the dead are exposed to vultures, demons, both male and female, hover around in millions.

If we take these myths and legends about demons and read them over, but with the difference that each time we came to the word "demon" we substitute for it the word "micro-organism," this word produces a marvellous change, and instead of reading over legends we seem to be perusing a modern treatise as disclosed by the results of scientific investigation. For instance, we find that the belief in micro-organisms (demons) is universal.

Haunts.—Micro-organisms (demons) are associated with impure places—wells, ruined houses, and market places, offal, crumbs, drinking water. Graveyards are their favourite resort, and they are found around the darkhmas where the Parsees expose their dead.

Food.—Micro-organisms (demons) feed on the blood and (odours) secretions of their victims; they enter into the bodies of animals.

Diseases set up.—The absence of immunity (the loss of the divine image) has rendered man subject to micro-organisms (demons) of mischief and destruction. They injure those who are susceptible to their influence (fall into their hands), and are specially dangerous to children. Drinking of water is sometimes bad for causing infection (for getting demons). Inhalation and swallowing of microbes (demons) are the causes of ill-health and diseases as plagues, epilepsy, acute mania, eruptions, leprosy, rabies, croup, asthma, infantile convulsions.

Diagnosis.—The microscope (an eye salve) enables micro-organisms (demons) to be seen, and proves their existence to the most sceptical. Microbes causing certain diseases are distinguishable from those causing other kinds of diseases (some demons are black, others blind).

Treatment.—Circumcision is good. Micro-organisms (demons) are rendered harmless to a great extent (propitiated) by ablutions and washing of hands, fumigation (pungent odours and loathsome smells), disinfectants (wine and salt), Röntgen rays, and radium emanations (charms).

The best thing to destroy (combat) them is cremation (fire in the form of torchlight and sacrifices).

Micro-organisms (demons) whose influences are beneficial: these (demons) are resorted to for the cure of disease—this can now be actually experienced in cases of smallpox, hydrophobia, diphtheria, etc.

Some micro-organisms (demons) exist which do good and are beneficial. This we now know is the case, for not only are micro-organisms utilised in many of our most important industries, but in the economy of nature they carry out important functions in connection with the fertilisation of the soil, and without their assistance life would soon cease.

In conclusion, I think it is remarkable that such a close agreement should exist between the ancient beliefs concerning demons and those now held about micro-organisms. Let any person who has studied bacteriology take up a book on demonology, and in perusing the latter he will imagine that he is reading over a modern treatise on bacteria and microbes, provided he substitutes, as has been said before, the word "micro-organism" for "demon." Can such a close agreement between the ideas of the ancients and those of the moderns be simply the result of chance, or is it more likely that the ancients in their crude ideas and beliefs have to a great extent anticipated modern science? This problem I leave with my readers to determine.

OPERATING THEATRES.

GREAT NORTHERN HOSPITAL.

Ruptured Urethra.—Mr. Arthur Edmunds operated on a boy, æt 12, who had been admitted with a history of having been knocked down by a motor-car. Apparently the car, which was going very slowly, struck him on the symphysis, and then one of the front wheels passed across the pelvis. The exact way in which the accident occurred, however, was a little uncertain.

On admission the boy was collapsed, there were a few scattered wounds about the head and face, and some abrasions on the thigh. On examination of the pelvis the iliac crests seemed a trifle loose, and any movement of them or of the ischial tuberosities caused pain. A skiagram was taken immediately, and it showed a fracture of the pelvis through the rami of the ischium and of the pubes on both sides, the symphysis being driven backwards. There was no escape of blood by the urethra, and there was a history that the boy had attempted to pass water but was unable to do so. A soft catheter was passed its full length, but drew off no urine. On withdrawing it, however, its eye was found to be filled with clot. The ease with which the catheter passed suggested that there was a rupture of the bladder. Accordingly the child was anæsthetised two hours after the accident, and prepared for operation. Under the anæsthetic it was possible to make out a swelling in the region of the bladder. The ordinary supra-pubic incision was made, but as it was a little difficult to identify the bladder a steel sound was passed again with the greatest ease. On cutting on to this, however, the bladder was opened without exposing the sound, a few drops of clear urine escaping. It was obvious, therefore, that the bladder had not been injured. The soft catheter and the sound had been passed into the loose cellular tissue behind the bladder. The patient was now put in the lithotomy position and the urethra exposed in the perineum. It was found that the urethra had been completely torn across; but its vesical end could not be found. A metal sound was therfore passed from the bladder into the perineal wound and a soft catheter passed down from the meatus through the ruptured distal end. One end of a thread was then tied round the tip of the soft catheter and the other end passed into the sound.; the soft catheter was next dragged into the bladder by means of this thread. The cellular tissue around the base of the bladder was found to be extensively lacerated, forming a cavity into which the instruments had passed at the first examination. The urethra was then sutured round the catheter, the two ends of which, one emerging from the meatus, the other from the supra-pubic wound, were next tied together, so as to keep the catheter in place. The perineal wound was then packed with iodoform gauze; the displacement of the symphysis was restored; the wound in the bladder was partially closed, a supra-pubic tube being left in; the lacerated cavity was also drained by one tube on each side of the bladder; the supra-pubic wound was then partially sutured, room being left for the tubes; and finally, dressings were applied.

Mr. Edmunds said the interesting points of the case were, first, the way in which it simulated rupture of the bladder, which was much more likely to have happened, and, secondly, the difficulty of finding the upper end of the urethra.

A week later the catheter was cut and drawn down so that the end lay in the bladder. Ten days after the operation the condition was that the wounds were all healing, the perineal wound being practically closed. The temperature and pulse had remained normal, and the boy had once passed water naturally.

Mr. Edmunds considered that the reason the patient had done so well was entirely due to the fact of the operation having been done at once, before any extensive infiltration of urine had taken place.

SPECIAL REPORTS.

THE SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE, LONDON, 1913.

CONCLUDING NOTICE.

The Medical Exhibition.

Special mention must be made of the magnificent exhibit of the products of Messrs. A. Wulfing and Co., of 12, Chenies Street, W.C. The fact that the Grand Prix of the Congress was awarded to Sanatogen—the only Grand Prix awarded in the food section—speaks for itself. The reputation of Sanatogen has been steadily built up upon a sterling basis of real clinical worth. Other exhibits of the same firm were formamint, albulactin, and a new preparation of hexamethylene-tetramine and sodium acetate known as cystopurin, which has already been favourably received by the profession in cases of infective conditions about the urinary tract.

The Saccharin Corporation, Ltd., were showing their pergenol, a solid compound of hydrogen peroxide, dissolving immediately in water to make a neutral solution of hydrogen peroxide and boric acid. Other interesting exhibits by the same firm were novocain; trivalin, a nerve tonic and anodyne; and dry diamalt, a British-made extract of malt in a crystalline powder.

Surgical Instruments and Apparatus and Miscellaneous.

An interesting exhibit was furnished by Messrs. Allen and Hanburys, Ltd., who were showing various instruments for the surgical treatment of fractures by Sir Arbuthnot Lane, Bart., and others. An improved irrigator stand by Mr. Canny Ryall, F.R.C.S., was also shown.

Invalid chairs and couches were shown by Messrs. John Ward, Ltd., 246, Tottenham Court Road, W. A comprehensive collection of bedsteads and cots for wheeling-out, as well as hospital lockers, was exhibited by Messrs. J. Nesbit-Evans and Co., of Birmingham. Optical instruments and sphigmographs were represented by the exhibits of George Spiller, Ltd.; Carl Zeiss (London), Ltd.; F. Leitz; Bruce Green and Co.; and John Weiss and Son, Ltd. A large assortment of surgical instruments were shown by Messrs. Mayer and Meltzer, the Medical Supply Association, Messrs. Hawksley and Sons, Messrs. Reynolds and Branson, Ltd. (Leeds), and the Holborn Surgical Instrument Co. Incubators for bacteriological work were exhibited by Messrs. Chas. Hearson and Co., Ltd.; Carl Zeiss (London), Ltd.; and Mr. R. B. Turner, 11 and 12, Foster Lane, Cheapside.

Of X-ray and electrical apparatus there were numerous exhibits of a costly and elaborate type, among which may be mentioned those of the Sanitas Electrical Co., Ltd.; the Veifa Works (Frankfort, a.M.); Siemens Bros. and Co., Ltd. (Westminster); Messrs. Schall and Son, New Cavendish Street, W.; and Messrs. Gaiffe (Paris), represented by the Medical Supply Association. Radium, Ltd., of 93, Mortimer Street, W., were showing their drinking and inhalation apparatus. Dr. Jaeger's Sanitary Woollen System Co., Ltd., and the Dr. Deimel underwear were each exhibiting their well-known specialities in clothing. The "Hopwood Baby Tether" was a capital device for keeping children safe and comfortable in cots and perambulators, and was shown by Messrs. John Bell and Croyden, Ltd., of Wigmore Street, W. The principal medical publishers were well represented, among whom may be mentioned Messrs. Adlard and Son, Mr. Edward Arnold, Messrs. Bailliere, Tindall and Cox, Messrs. Cassell and Co., Ltd., Messrs. Henry Frowde and Hodder and Stoughton, Mr. H. K. Lewis, Messrs. J. B. Lippincott Co., Messrs. Rebman, Ltd., and Messrs. W. B. Saunders Co.

Other awards to exhibitors than those already mentioned were to Messrs. Wulfing and Co., London, the Grand Prize in the Food Section for "Sanatogen"; a gold medal to Messrs. Southall Bros. and Barclay, of Birmingham, for their new food tonic, "Vitafer"; and a gold medal to the Ronuk Company for their sanitary floor polishes and appliances.

MEDICO-MECHANICAL TREATMENT IN ENGLAND.

Treatment by means of medico-mechanical appliances, as carried out in the so-called "Zander" institutes, has, for some inscrutable reason, never become popular in England, though it is employed extensively on the Continent and in America. Speaking generally, it may be said that the various apparatus are designed to carry out, by mechanical means, the various movements and manipulations embodied in the Swedish system of physical treatment. This treatment is of the greatest value in restoring the function of joints disabled in consequence of injury as well as in chronic joint affections due to disease. The treatment, however, is not limited to these, for it is also advantageously applied in secondary muscular atrophy and in certain forms of paralysis, neuritis, and neurasthenia. In the more purely medical domain, treatment by regulated movement is brought to bear in diseases of the heart and respiratory organs, constituting, as it does, a method of cardiac and respiratory gymnastics. It is plain, therefore, that medico-mechanical treatment has a wide field of application, adjuvant to the ordinary medical and surgical measures. Two or three years since, Mr. Edgar Allen, of Sheffield, a large employer of labour, having himself derived great benefit from the use of the Zander apparatus abroad, founded a perfectly equipped institution of the kind in that town which he placed at the disposal of the medical profession in the sense that cases were only admitted for treatment on the recommendation of a medical practitioner. Not content with organising the institute, which bears his name, he generously provided funds for carrying it on for three years, hoping that at the expiration of that period its value would have become sufficiently apparent to induce employers of labour and insurance companies to make financial arrangements for its being carried on. The second annual report, which has just been issued, shows indeed that the working classes fully appreciate the advantages thus rendered available, upwards of 150 cases being treated daily. The time is now approaching, however, when arrangements will have to be made to provide the necessary funds to enable the institution to continue its beneficent work. In private hands it could easily be made a paying concern, but as the object of its foundation was to benefit the working man, no plan which would deprive them of access would be acceptable to its generous founder. It is to be hoped that the public spirit of employers of labour and others will induce them to take this question in hand. It would not be fair to expect the founder, who has already expended many thousands of pounds in fitting it up and keeping it going, under the superintendence of a medical officer, to bear the burden of its maintenance indefinitely. It lies with the Sheffield Press to make its claims known and to render its continuance possible.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, Aug 23rd, 1913.

At the Congress for Laryngology, Hr. Kilian, Berlin, spoke on

The Occurrence of Accidental Infections after Clearing Out the Antrum of Highmore.

He said that when an old deposit of pus in the antrum, either through the natural opening in the mouth or through a puncture, even when the part was washed out with a sterile saline solution, it often happened that in a few hours there was a moderate rise of temperature. Sometimes the rise was preceded by a rigor. The temperature might even be as high as 39° C. This lasted generally at most a few hours. The day following the patient generally felt quite well. These occurrences were usually observed only at the first washing out. Plainly the whole chain of symptoms was the result of absorption of bacilli through the mucous membrane of the antrum, and not the result of infection. A case deserving of mention was one in which the sight of the eye of the corresponding side failed completely, but the disturbance passed off quickly, although the pupil of the eye remained dilated for several days.

The vagus reflexes observed in some sensitive individuals, after washing out of the antrum, were interesting at times. Slowing of the pulse, fainting, and very rarely sudden death had been observed. A case of the latter kind occurred in the speaker's polyklinik a few years ago. It could not be ascertained that the fluid with which the washing out was done was cold. The autopsy revealed nothing, and nothing special could be seen about the heart.

At the Gynæcological Congress, Hr. Klein, München, spoke on the

Röntgen Treatment of Myomata and Fibromata of the Uterus.

From May, 1911, to March, 1913, 46 cases of myoma and 35 of fibroma had been treated by Röntgen rays. The principles on which the treatment was carried out were not to send more rays into the body than were actually required for the treatment of the case. With from 50 to 100 X in from two to seven series the desired amenorrhœa or oligomenorrhœa had been successfully achieved. They had only noticed a passing reddening once, otherwise no bye-effects whatever. Another principle they had carried out was always to operate in young women with myomata rather than Röntgenise. Here it was certainly justifiable to remove the myoma and leave not only the ovaries but every millimetre of sound corpus and cervical tissue. The troubles of the menopause might be exceedingly troublesome and very persistent in young women. One third of their myoma cases that had been operated on still menstruated. Of the patients treated up to March last most had already become amenorrhœic. He had already stated elsewhere that they always operated where there was a suspicion of malignancy or that a myoma was degenerated. In common with all other authorities they had the best results in cases of fibroma. Of the 35 cases of that class there had not been a single failure.

Hr. Theilhaber spoke on the

Influence of the Climacteric on the Development of Carcinoma of the Genitals.

He said that the tendency to carcinoma of the genitals was in inverse proportion to the amount of cells contained in the connective tissue and the degree of vascularity. The basis of this was a disturbance of the equilibrium between the epithelial and connective tissue cells. The epithelial cells could then pass more readily when older disease processes had been present so that the poverty in cells and the low degree of vascularity of the connective tissue such as cicatricial tissue and chronic inflammations were contributory. From a therapeutical point of view these considerations and also the practical experiences of the speaker, the indication was to strengthen the constitution as much as possible, and set up a cyclical hyperæmia of cicatrices by means of cupping glasses, massage, diathermia, injections of uterine juice, etc. In the treatment of carcinoma itself it appeared rational to put all these methods into practice—the hyperæmisation and the excitation of round-celled inflammation. Here were also in place diathermia, combined with Röntgenisation, radium, or mesothorium, cholin, uterine extract, etc.

Hr. Kroemer, Greifswald, spoke on the

Action of Mesothorium on New Growths of the Genital Organs.

He said that although the results were not gratifying in very advanced cases, they had been much so in nine cases of cancer of the cervix that had appeared to be hopeless, as they had allowed total extirpation to be performed later on. Similar good results had been seen in some few cases of cancer of the body of the uterus, one with vaginal metastasis, and above all, in rodent ulcer of the vulva. In all cases that came to operation the cicatrix was treated by mesothorium two to three hours a day during convalescence. The amount of radiation lay between the following limits: The cases of cancer of the cervix, 3,000 to 7,000 mg. hours supported by X-rays in which every 10 to 11 days up to 100 were made use of. At the same time the patients received thorium X by the mouth—100 e.s. E. Aqueous solutions were also made use of. Absolute cure in which the disease was wholly cast off was only met with in two cases. In most of the cases, advancing disease was still demonstrable in the deeper-lying layers of tissue. Mesothorium treament in combination with deep Röntgen treatment promised permanent recovery in all external forms of the disease, the portio vaginalis, the vagina and vulva. It supported the operative treatment in so far as in improved inoperable cases it at least removed the putrefaction and the fœtor.

HUNGARY.

Budapest, Aug. 23rd, 1913.

At the recent meeting of the Interhospital Association, Dr. B. Kovàcs read a paper on

Surgical Intervention in Renal Disease.

He said that no branch of surgery has received such tremendous impetus of late years as this. He divides the subject into three heads, intervention in acute nephritis, in chronic nephritis, and finally in certain essentially medical affections of the kidney itself. The acute conditions, which are further sub-divided into those arising from ascending infection, those of a circulatory type, and those of mixed type, are discussed with admirable clearness and the effect of various treatments indicated. Dr. Kovàcs seems absolutely just in his treatment of the two opposing theories or technics, as they should more rightly be called, of decapsulation and kidney incision. He traced the steps by which Pousson reached his conclusions as to the efficiency of renal section, and shows to what a degreee they resemble the steps by which Edebahls arrived at a very similar conclusion in regard of decapsulation. The review of decapsulation literature has convinced the reader of the advantages of this method. As to the choice between the Pousson or the Edebahls operation, he said, that in considering the two, the brilliant researches of the English surgeon, Harrison, should not be forgotten. To this early observer the tense capsule of the congested kidney of acute nephritis bore the same relation to that organ as the iris to the eye in cases of glaucoma. Furthermore, in the opinion of the reader, although decortication does not appear to present either great technical difficulties or to entail serious post-operative complications, it is, nevertheless, well to recollect that it constitutes in every case a somewhat more difficult intervention, and one certainly more grave in its possible sequels than simple section of the kidneys. A further and even greater objection to decortication would appear to be that its benefits do not begin to show themselves until at the end of eight or ten days at the minimum, whereas, on the other hand, Pousson's nephrotomy gives immediate results. Continuing, he said: It is essential to remember that the very principle of the technic of decortication has been brought under very severe criticism from a histological standpoint, it having been shown that the supposed increase of vascularity between the parenchyma of the kidney and the perirenal tissue probably exists either to a very small extent or else not at all. The good arising from decapsulation, then, must be attributed to a release of the endonephritic tension, or else to a stimulation of the reflex renal nervous system. Accordingly, the conclusion is that, in the present status, no positive choice can be made between decapsulation and nephrotomy in the treatment of chronic nephritis.

On the Ætiology of Eczema.

Dr. A. Roth said that despite of all that has been written and said about eczema, the ætiology of this most common skin disease is still obscure. Dr. Roth cannot share the view of Unna, that eczema is primarily a parasitic disease, for the vesicles of the early stages have time and time again been proven sterile, and even inveterate cases will sometimes heal with treatment which is directly opposed to all rules of asepsis. Most likely a specific predisposition combined with a local or general irritation are the underlying causes, and more good can generally be accomplished by antiseptic local dressings. There is a distinct relationship between the skin and the internal organs; thus an eczema of the head, when treated energetically, will sometimes be followed by compensatory hyperæmia of the brain, manifesting itself in convulsions, and an intercurrent attack of diarrhœa will frequently improve an eczema of the body.

Treatment of Chronic Eczema.

Prof. Havas recommends the following prescription in cases of old standing, obstinate eczema:—

Oxidi borici }
Zinci oxydati } aa. grammata, 10.0
Solve in glycerine qu. s.
Add
Unguenti Diachyli }
Vaselini } aa 45.00 grns.
N.D.S. To be applied under dressing.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

Local Medical Committee.

A meeting of the Local Medical Committee for the County Borough of Belfast was held in the Medical Institute on the 15th inst., Mr. R. J. Johnstone, F.R.C.S.Eng., presiding. The resolutions passed at the Delegates' Meeting, held in Dublin on the 17th July, were unanimously approved and adopted. Mr. Johnstone, Dr. T. A. Davison, and Dr. Stanley B. Coates were elected to represent the committee on th Irish Medical Committee recently formed. The profession in Belfast are determined not to accept service under the Insurance Act so long as the Chancellor of the Exchequer ignores the demands of the Irish medical profession for improvements in the working of the Act.

Visit of German Doctors to Belfast.

A party of German doctors numbering with their wives about 200, after attending the International Congress in London, have been making a tour round the United Kingdom in the Hamburg-American steamer, "Kronprinzessin Cecilie." The party paid a short visit to Belfast on the 21st inst., and were entertained by the Lord Mayor, Mr. R. J. McMordie, M.P., who had invited a number of medical men and others to meet the visitors. Refreshments were served in the large hall of the City Hall at 6.15 p.m., and the visitors, who could only stay a short time, were shown through the building. The Lord Mayor in the course of a short speech welcomed the visitors to Belfast and emphasised the importance of such meetings as tending to foster the most cordial feelings between the two great nations represented. He referred to the attention paid by the German empire to the matter of education, and congratulated them on the advances made by their great Empire in this as in other respects. Dr. Koenig, of Berlin, acted as interpreter for those not sufficiently acquainted with English. Professor Glax, Abbazia, Austria, in replying, thanked the Lord Mayor and other citizens of Belfast for the great kindness shown to them during their all too brief stay in Belfast, and promised a very cordial reception to any citizen of Belfast should he at any time find himself in the speaker's country. Sir Otto Jaffé, an ex-Lord Mayor of the City and now German Consul, in a lengthy speech in the German language referred to the vast progress that Belfast had made not only in regard to population and industries, but also in relation to educational, philanthropic and other institutions which made for the betterment of the community. He referred to the Royal Victoria Hospital, the Purdysburn Asylum, the Abbey Sanatorium and other institutions, and paid a fitting tribute to Sir Wm. Whitla, who had erected the Medical Institute in College Square for the benefit of the members of the medical profession. The party shortly after embarked on their way to Dublin.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents]

A DOCTOR'S WIFE ON DRESS.

To the Editor of The Medical Press and Circular.

Sir,—Women have their rights—some belong to them, some they assume. One of the latter is that of having the last word in an argument. Up to the present "mere man" has, no doubt, been highly entertained by this discussion, in which he has not ventured to join. But braving the presumption of breaking the spell, I am audacious enough to believe that "mere man," with all deference to his sisters, is still entitled to express his views upon the subject. First women must admit that their fashions in dress are always matters of extremes. In early Victorian days women did everything possible to conceal the fact that they were bipeds, by enveloping their bodies in skirts and petticoats balloonly distended with crinolines. Then many of us can remember the days of that curious supplement to their anatomy, technically named the "bustle." This was succeeded by a remarkable contrivance, constructed in the form of a wire cage, known as the "improver." This waggled about from side to side as they walked, and so left the true anatomy of their proportions to nebulous speculation. We all know what since has followed. The present fashion—it will not stay—is to reveal every lineament of a woman's figure—just the very opposite of that which the fashion of the crinoline subserved. "Mere man" looks on, is amused, and wonders what next will happen. His susceptibilities are hardened enough to believe that if a woman is persuaded that her gluteal muscles are of shapely proportions, she is entitled to exercise her right of letting everyone see how they contract if she likes. The only point in the case is the extreme of her decision which fashion has dictated. But fashion is no respecter of persons, and so women generally dres alike—and their dress is designed by no means for the benefit of "mere man" alone, but to a large measure to compete, for attraction, among themselves. This nudity craze, therefore, had better be left to settle itself—just as the crinoline monstrosity did—and the hirsute appendage, that Victorian abnormality, the chignon, which often seemed ponderable enough to give a woman's head a posterior "list." After the public exhibition of the lineaments of their figures, women will doubtless turn their attention to the last resource of their natural gifts—namely their hair. In the near future we may expect to see a neat development of fashion in this direction. The hair may come to be worn in all its pristine and attractive beauty, compelling admiration, despite the elevation of prudish fans employed to conceal the dazzle of its adornment. This letter may appear too cynical in respect to women's foibles, but it is not intended to be so. Logically we must admit that if Nature has designed woman intentionally with an eye to artistic effect—and this we may believe—it is not curious that a woman should refuse to hide her talents under a crinoline or anything else to which the law does not object.

Yours, etc.,
DOCTOR'S WIFE'S HUSBAND.

DR. EWART ON THE APEX TREATMENT OF CONSUMPTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—There can be only one opinion among your readers as to the value of the series of papers on "Apex Treatment for Pulmonary Consumption," which Dr. William Ewart has been contributing to your pages. I have read them with intense interest, and I am preserving them on the file that I keep for the purpose in similar instances for later reference and study. I am certain I am voicing the wishes of your subscribers when I offer our thanks to Dr. Ewart for his scientific, suggestive and practical contribution to the ætiology and treatment of phthisis. It is to be hoped that we shall hear more of the "treatment by unilateral breathing," but as the author wisely remarks, "This is a double-edged weapon. The art of its safe and successful use will have to be studied clinically." This has hitherto been the test by which previous theories have had to stand or fall, and if the author's views pass this test successfully he will have achieved much where others have failed, and we can then hope that he will not fail to put them into the more permanent book form which they will in such case fully deserve.

I am, etc.,
SENEX.

London, W.,
August 22nd, 1913.

OBITUARY.

MR. W. WHITEHEAD, OF MANCHESTER.

WE regret to announce the death of Mr. Walter Whitehead, F.R.S.E., the well-known Manchester surgeon, which took place on the 19th inst. at Colwyn Bay, aged 73. The deceased was educated at Altrincham and Ripponden, and at the age of sixteen he entered his father's bleaching business. This proving uncongenial, he soon left it, and, having borrowed enough money to pay his lecture fees, he entered the Chatham Street School of Medicine, Manchester, unknown to his parents. While still a student he followed the custom of the day and was apprenticed to two doctors in partnership at Bury. He qualified in 1864 by taking the L.S.A (London), and the L.F.P.S. (Glasgow), and the L.M. (Edinburgh). In 1866 he added the F.R.C.S. of Edinburgh. Mr. Whitehead then purchased a practice at Mansfield Woodhouse, Notts, where he stayed until 1867. Returning to Manchester Mr. Whitehead was, first, honorary surgeon to the St. Mary's Hospital for Women and Children (1868), and then honorary assistant surgeon to the Manchester Royal Infirmary (1873). He remained on the staff of the latter institution until 1900, when he retired, having reached the age limit of 60. For a time he was professor of clinical surgery and examiner in the Victoria University of Manchester. He was, however, not a good lecturer, being a much better exponent of his profession to senior and qualified men at the bedside. He was also honorary surgeon to the Manchester Lock and Skin Hospital and to the Christie Cancer Pavilion, and was mainly instrumental in the foundation of the Manchester Hospital for Diseases of the Skin.

Mr. Whitehead wrote many papers, more or less original in nature, for medical journals, those best known being descriptive of the two operations which brought him world-wide renown. These were for removal of the tongue and for removal of hæmmorrhoids. Both of the operations were characterised by the use of blunt-pointed scissors for the cutting stages. In his hands, and also in those of other surgeons who carried out his instructions carefully, the operations were, and still are, very successful, and they are described in all standard works of surgery, and referred to as "Whitehead's Operations." Originality was a characteristic of his family, whose members included the inventor of the Whitehead torpedo, and John Kay, the inventor of the fly shuttle. He also wrote the articles on "Affections of the Mouth" and the "Surgery of the Thyroid Gland" in Treves's "System of Operative Surgery" (1885). When the British Medical Association visited Manchester in 1902 he was unhesitatingly selected as its president, and the unanimity of the choice is the best possible evidence of his professional position and personal popularity. For many years of his life yachting was Mr. Whitehead's hobby, mostly at Windermere, where he was Commodore of the Royal Yacht Club in 1889. When he retired from active work he lived chiefly at Colwyn Bay, where he bought a good deal of property, including the local landmark known as Flagstaff Hill.

DR. L. EASTWOOD, OF DARLINGTON.

THE death took place on the 11th inst., at his residence, Brookside, Darlington, of Dr. Lewis Eastwood, J.P., aged 62. The deceased, who qualified as L.R.C.P. and S.Edin., and L.S.A.Lond., in 1877, was a native of Illingworth, near Halifax. He came to Darlington in 1871 as assistant to the late Dr. Howison, of Grange-road, and six years later began to practise on his own account. For sixteen years he was surgeon to the Darlington Hospital, but had to resign that position owing to pressure of work. Over a very long period he was surgeon to the Darlington Police Division, and he had also held appointments in connection with some of the large works of the town, notably the Forge. He was a familiar figure about the town, usually with his bicycle, for he was an ardent cyclist.

The late Dr. Eastwood rendered admirable service to the municipal life of the town. He first opposed the late Mr. Green in the North Ward, but without success, and when a vacancy occurred in that ward owing to the elevation of Mr. Green to the Aldermanic bench Dr. Eastwood proved successful over Mr. John Robinson, though the latter had not long to wait before he entered the Council. It was in the work of the Health and Sanitary Committee that Dr. Eastwood threw his heart and soul, and his medical knowledge in this department stood him in good stead. In 1910 he was elected Mayor of Darlington, and ably assisted by Mrs. Eastwood as Mayoress he carried out the duties during a year which included the coronation of King George with much acceptance, entering heartily into the festivities associated with that occasion. He was also a member of the Advisory Committee appointed to advise the Lord Chancellor in the selection of magistrates. An enthusiastic musician, he was associated with the Darlington Orchestral Society for twenty years, and occupied a place in the orchestra as a violinist. He had an interesting collection of violins by famous makers, which he delighted to show his friends. Dr. Eastwood was a Churchman and a Unionist, and for nearly 30 years he was a Freemason, being a member of the Marquis of Ripon Lodge. Dr. Eastwood was twice married.

SUMMARY OF RECENT MEDICAL LITERATURE ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

Treatment of Uterine Hæmorrhage by Röntgen Rays.—Pfahler (*Amer. Jnl. Obs.* lxvii., 5) gives a series of cases treated by this method, and says that Röntgenotherapy is the method of choice for the control of hæmorrhage in patients approaching the menopause, in whom carcinoma can be eliminated. It is not the method of choice in cases under 40 years of age. It can be recommended in all cases at any age where operation is contra-indicated. For the differential diagnosis, in order to determine the indications for this treatment special skill in gynæcology is required, and for the proper administration special training in Röntgen therapy is necessary. The advantages are painlessness, avoidance of shock of operation, preservation of internal secretion; moreover, it does not interrupt the usual habits, confinement in hospital is avoided, it is without risk in the hands of a skilful operator, the menopause is brought on gradually when necessary, and the amount of treatment can be graded to the needs of the patient. The disadvantages are—the prolonged course of treatment that is usually necessary; there is danger to the overlying tissues if the rays are not properly applied. The treatment is more expensive than operation. F.

Menstrual Molimina.—Chesholm (*Jnl. Obs. and Gyn. Bt. Emp.*, xxiii., 5) from the records of 500 girls who had commenced menstrual life concludes that the majority of girls commence menstruation painlessly, that a number have discomfort, some occasionally, some regularly, for a time varying from one hour to two days, just before and with the commencement of the menstrual period. This discomfort is often slight in character. A few have more severe pain, either regularly or occasionally; a very small number are incapacitated; a small number, 1.2 per cent., have discomfort or pain for a longer period than one or two days during the whole of menstruation. The discomfort in girls is most frequently local, and when there is general disturbance it is accompanied by severe local pain and probably proceeds from some local abnormality, congenital or acquired. The best developed girls appear less likely to have disturbance. The percentage in chlorotic girls is higher than the general average. The freedom from discomfort is not affected by hard mental work carried on under healthy conditions. F.

The Pathology of Uterine Casts passed during Menstruation.—Bell (*Jnl. Gyn. and Obs.*, xvi., 6) hopes to prove that it is an erroneous idea that menstrual endometrial casts are the product of conception, although abortions do occur and may be confused with true menstrual casts. Casts may be divided into—(1) True blood casts of the uterus; (2) thick casts; (3) thin casts. With regard to the difference in thickness this is considered to be due solely to the depth of the endometrial denudation. The menstrual decidual reaction prevents the blood breaking through easily, and consequently the menstrual blood strips up the superficial portion of the endometrium instead of passing through it. From a study of specimens there is a distinct difference between the decidua-like change in the cells of the stroma and that of pregnancy, and there is a marked effusion of blood serum amongst the cells which is not seen in the decidua of pregnancy. F.

Thread-worms in the Peritoneal Cavity simulating Meningitis.—Whitelocke (*Brit. Journ. of Children's Diseases*, July, 1913) records the very remarkable case of a girl, aged five and a half years, who was admitted to hospital with the diagnosis of tuberculous meningitis. The child was very ill on admission to hospital, having a temperature of 102.4° F. and a pulse of 112. She had marked converging strabismus, with contraction of both pupils and some photophobia. There was a history of an enlarged gland having been removed from her neck a year previously, after which she had appeared well till the present illness, which set in somewhat suddenly thirty-six hours before her admission to hospital. Since that time she had vomited frequently, screamed a good deal, refused food, and had incontinence of urine. For two days after admission to hospital she remained in much the same condition, picking at the bedclothes, being very restless, and wetting herself more frequently. Whitelocke then noticed that though she tossed about in bed she continuously kept her right leg rigid and more or less flexed on the abdomen; the left leg she moved freely. Careful examination of the abdomen revealed some rigidity of the right rectus muscle, and even gentle pressure in the region of the cæcum caused her to call out loudly. The abdomen was then opened and an inflamed process of omentum was found attached to the cæcum, covering it and the appendix completely. On removing this omentum a nest of about a dozen dead thread-worms was found, and a small pin-hole perforation was found in the appendix on its mesial aspect, about three quarters of an inch from its distal extremity. Through this perforation a living thread-worm was seen wriggling. The appendix was then removed, and careful search revealed the presence of seven more worms free in the cavity of the peritoneum. When the appendix was opened it was found to be crammed full of worms of all sizes and ages, and the mucous membrane was considerably ulcerated, especially in the neighbourhood of the perforation. After the operation the nervous symptoms and sickness quickly disappeared and the child made a complete and rapid recovery. K.

Anterior Poliomyelitis.—Hazen (*New York Med Journ.*, July 12th, 1913) discusses the treatment of this disease and comes to the following conclusions. In order to prevent infection, attention should be paid to the hygiene of the mouth and throat. The careful use of the tooth-brush and a non-irritating douche and gargle should be regularly attended to; menthol preparations being recommended for antiseptic purposes. Complete rest is essential in the acute stage of the disease, and the avoidance of fatigue is of the utmost importance during convalescence. In the after treatment "prosthetic appliances, passive motion, massage, electricity, hydrotherapy, mechanical vibration, and exercise" are strongly recommended. The prevention of deformity, the keeping up of function and growth in the damaged members, with re-education of nerve and muscle are important factors in success, and should be continued even after the adoption of suitable surgical measures. K.

Administration of Extract of the Pituitary Gland.—Musser (*Amer. Journ. Med. Sciences*, August, 1913) records the results of an investigation undertaken in order to study more particularly the effect of pituitary extract upon the blood pressure when administered by the mouth over a more or less prolonged period. Eighteen individuals were given the dried extract of the whole pituitary gland without other medication. It was noticed that the administration of extracts of the gland exerts a distinct pressor effect on the peripheral vascular apparatus, which persists for an appreciable time after discontinuation of the drug. This is apparently the only consistent effect following continued administration of the gland by the mouth; other results are variable and indefinite. K.

Duodenal Ulcer in Infancy.—Schmidt (*Med. Review,* July, 1913) reports that during the past seven years 20 cases of fatal duodenal ulcer were discovered *post mortem* among children less than a year old. This represents 1.8 per cent. of the necropsies at that period of life. The writer concludes that duodenal ulceration is more common during the first year of life than at any other period. The reason why this observation has not previously been made is that duodenal ulcer is chiefly treated by the surgeon, and the general health of infants with this condition is usually too bad to warrant an operation. In the majority of the writer's series the infants were emaciated. Some suffered from purulent inflammation, phlegmon or digestive disturbances due to rickets, whooping cough, tuberculous meningitis. In no case had the infant suffered from burns of the skin. The diagnosis of duodenal ulcer in infants is seldom made before a fatal hæmorrhage from the rectum or mouth occurs. Only in two of the writer's series was the disease discovered during life. In fourteen cases no symptoms pointed to this condition. Though one necropsy showed a healed scar in an infant, the writer considers that recovery from duodenal ulcer in early life is most exceptional. S.

Three Unusual Cases of Renal Tumour.—Joly (*Practitioner,* August, 1913) reports the operative treatment he employed in the radical removal of kidney tumours. A case of hypernephroma and one of primary cancer of the kidney made excellent recoveries, and remained well, without any sign of recurrence about two years after the operation. The third case, also of hypernephroma, lost so much blood before he would consent to operation, that a fatal termination occurred. The writer removes the fatty capsule unopened with the kidney enclosed, in each case. He describes the following incision and procedure which gave him very good access to the malignant renal growth. The vertical limb was five inches long and parallel to and immediately outside the left linea semilunaris, its centre being opposite the umbilicus. The tumour was palpated through this opening and proved to be renal in origin. The pedicle was free from induration and there were no glands along the aorta. The peritoneum was closed, and a long incision made from the centre of the first one outwards and slightly upwards to a point about an inch below and in front of the tip of the last rib. The peritoneum was exposed in the anterior part of the incision, and the perinephritic fat in the posterior. The peritoneum was raised from the front of the tumour, and retracted inwards towards the middle line. Next the hand was insinuated behind the fatty capsule, which was separated from the muscles of the lumbar fossa. Finally the kidney (enclosed in its fatty capsule) was completely freed from all its connections, except those on its inner aspect. The ureter was divided just above the brim of the pelvis. The tumour was retracted strongly outwards, and the tissues separated from the side of the aorta. This dissection was made from below upwards. When the renal pedicle was reached, it was clamped and divided, as were also the capsular vessels. The tumour was thus completely freed and removed out of the lumbar fossa. It weighed 3¾ lbs. The patient made a good recovery and gained 4 stone in weight. In spite of the pain due to this the abdominal wall remained quite firm, and there was no evidence of recurrence a year and nine months later. S.

MEDICAL NEWS IN BRIEF.

Visit of German Medical Men to Dublin.

Last Friday morning one hundred and fifty German physicians, accompanied by seventy ladies, arrived in Dublin. They came from Belfast to Kingstown in the 9,000 ton vessel, the "Kronprinzessin Cecilie," of the Hamburg-American Line. On landing from their ship, the party were conveyed in special tramcars to Dublin. The first institution they visited was Trinity College. Here they were received by Professor A. F. Dixon, who conducted them through the Medical School, the Library, the Chapel, and others of the College buildings. Leaving Trinity College, the party divided into five or six detachments, and in open wagonettes drove round to see the show places of the city. A party of twenty went in motor cars to the Peamount Sanatorium, at the invitation of the Countess of Aberdeen. Another visited the Rotunda Hospital and the Mater Misericordiæ Hospital, and returned by the Richmond and Whitworth Hospitals to Christ Church Cathedral, the City Hall, Dublin Castle, St. Patrick's Cathedral, and the Royal College of Surgeons. A third section of the tourists drove over O'Connell Bridge, along the North quays, past the Four Courts to Kingsbridge, past Steevens' Hospital, to Guinness's Brewery, returning by Christ Church Cathedral, St. Patrick's Cathedral, to the Royal College of Surgeons. The fourth tour was from the College up Grafton Street, Nassau Street, Kildare Street, to the National Museum and the Library, which they inspected with keen interest. They also visited the National Picture Gallery and the collection of Irish National Portraits, and then proceeded to the College of Science, took a glance at the buildings of the National University and the Municipal Gallery of Modern Art, Harcourt Street. At one o'clock the entire party assembled at the Mansion House, where, by permission of the Lord Mayor, luncheon was served by Mr. Mills, caterer, Merrion Row. The Lord Mayor was unable to be present, because at that time he was presiding over a special meeting of the Municipal Council in the City Hall.

After luncheon carriages conveyed the visitors from the Mansion House to the Royal Zoological Gardens in the Phœnix Park. They walked through the Gardens to the Viceregal Lodge, where the Lord Lieutenant and the Countess of Aberdeen gave a garden party in honour of the visitors. After the Viceregal "Empfang," the entire party drove down to the Nelson Pillar, where they boarded special tramcars which conveyed them to Kingstown, where they re-embarked and set sail at nine o'clock for Jersey and the Channel Islands.

An Unusual Increase in the Birth-Rate.

So rarely has the Registrar-General to record an increase in any of his percentages that it must have been a real pleasure to him to issue his quarterly return on this occasion. Cupid has been busy, and there were 60,864 marriages in the first quarter of the present year. That compares with 44,661 in the like period last year, and is higher by some thousands than the figures in any first quarter for ten years past. We fancy we may take the sudden disposition to marriage as an additional testimony to the prosperity of the country, and we may look forward to the increasing number of marriages giving a fillip to the birth-rate in the future. There was a decided increase in births in the quarter under review, and with the death-rate still declining, it looks as if we were in for a brief period in which the pessimists about these matters will have less occasion for their gloom.

Enteritis from a Dust Heap.

At a meeting of the Southwark Board of Guardians on Friday last a report was read from Dr. H. W. Bruce, medical superintendent at the infirmary, stating there had been 18 cases of infective enteritis among young children patients in the institution, and that four had died. He attributed the outbreak entirely to the poisoning of the children by the refuse on the railway siding, which was being removed by the Camberwell Borough Council. The facts have been laid before the Local Government Board, and the guardians have decided to take immediate action in the case.

A King Edward VII. Memorial in Guiana.

To perpetuate the memory of the late King Edward, the colonists, with the co-operation of the Combined Court, have erected a model dispensary for the prevention and treatment of tuberculosis, in which, as is known the world over, His Majesty took a profound interest. Erected at a cost of close on $4,000, the dispensary was opened by his Excellency the Governor, Sir Walter Egerton, on July 22nd, in the presence of the most prominent citizens.

The idea of the memorial taking the form it does emanated from the Surgeon-General, the Hon. Dr. J. E. Godfrey, now on furlough in Scotland. The Governor paid a fitting tribute to Dr. Godfrey's interest and zeal, both with regard to his conception of the memorial and in arresting the death-rate for which tuberculosis is responsible in the

left the following direction in his will:—"I desire to be buried in the same grave with my late beloved wife. The inscription on the gravestone is to be, in addition to the names and dates, 'A Man of Hope and Forward-Looking Mind.'"

He left the following directions regarding his museums at Selby, his native place, Haslemere, and Chenies Street, London:—"I leave the three museums at Haslemere, Selby, and 22, Chenies Street, and their contents to my trustees upon trust to dispose of the same as they in their own absolute discretion shall think best, but my desire is that, without imposing any trust upon my said trustees, they shall dispose of my said museums and their contents in accordance with my wishes expressed to them during my life."

Accidental Death of an Army Medical Officer.

Major George Buchanan, Royal Army Medical Corps, who had been lying in the Hampstead General Hospital since Thursday as the result of the accidental discharge of a revolver, died on Saturday morning last. Deceased, who had not long returned from India, was showing the revolver to a friend at Harvard Court, West Hampstead, his residence, believing it to be unloaded, when a single live cartridge which had inadvertently been left in it exploded. The Major was wounded in the stomach, from which he succumbed two days later. At an inquest held yesterday, a verdict of accidental death was returned.

Anti-Typhoid Inoculation.

At a recent important discussion at the Royal Military College, Millbank, some important contributions to the subject were made, particularly in regard to the inoculation against typhoid of British soldiers in India. Colonel Sir William Leishman (Royal Army Medical Corps), Professor of Pathology, Royal Army Medical College, said that since he had the honour, in 1907, of acting as reporter on this subject at the International Congress of Hygiene at Berlin, anti-typhoid inoculation had come to occupy a very important place in military medicine. At that time it was very far from being generally accepted as a practical measure, although its protective value was recognised by most bacteriologists. Now, he thought, it might be said to be generally regarded as one of the most powerful weapons in the fight against typhoid fever. In the Army they had now accumulated a very considerable body of experience in the practical use of the vaccine. They were the first to adopt the method as a preventive measure on a large scale, and, although its general acceptance had been a slow process, and it still remained on a purely voluntary basis, it was now widely taken advantage of by the soldiers, and had few, if any, strong opponents in either the combatant or the medical branches of the Army.

The next Eugenics Congress.

At its first annual meeting, which was held in Paris, the Permanent International Eugenics Committee accepted the invitation of Dr. C. B. Davenport, of Cold Spring Harbour, Long Island, to hold the next International Eugenics Congress in the United States next year, probably in the month of September. The committee, after discussion, also agreed to he establishment of an International Engenics ibliography. Among those who attended the meeting ere Major Darwin, Mrs. Gotto, and Professor chuster (England), Professor Adams Woods (America, r. Mjoen (Norway), Dr. Plock (Germany), Professor ini (Italy), Dr. Soren Hansen and Mr. Vincent aeser (Denmark), and a number of eminent French genists, including Professor Frederic Houssay, rofessor Faure, and M. Lucien March, Directeur of e Statisque Générale de la France.

lingering by Insured Persons.

A special committee has been appointed to inquire o the allegations of excessive sickness claims malingering among insured persons. Sir Claud uster, the legal member of the English Insurance Commission, is chairman, and among the other members are Miss Mona Wilson, the lady member of the Commission, Miss Mary Macarthur, Secretary of the Women's Trade Union League, Mr. W. P. Wright, Grand Master of the Manchester Unity, Mr. A. H. Warren, President of the National Conference of Friendly Societies, Mr. Walter Davies, Sons of Temperance Society, the Chairman of the Manchester Insurance Committee, and three representatives of the medical profession.

The terms of reference are "to inquire into and report upon the alleged excessive claims upon and allowances by approved societies in England in respect of sickness benefit and any special circumstances which may cause any such claims or allowances." The investigation is limited to England. A full inquiry will be made into the allegations of malingering, particularly among women, and into the assertions that panel doctors have granted medical certificates to insured persons without proper examination and for trivial ailments.

Society of Apothecaries of London.

The following candidates, having passed the necessary examinations, have been awarded the L.S.A. Diploma of the Society, entitling them to practise medicine, surgery, and midwifery:—

T. H. Cresswell, P. R. Cross, H. G. Marshall, O. Marshall, and C. E. Reckitt.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

T. W. F. (Birmingham).—The rule is a standard one—"always verify your references." The reference to which our correspondent alludes is presumably incorrectly given, and we regret that we cannot help him.

DR. M. W. (Dublin).—We have forwarded the newspaper cutting to the author referred to.

M.D. ST. ANDREWS.—A novel based upon a purely psychological problem might appeal to a certain class of readers, and might even prove a success, but underlying it there would necessarily have to be a firm substratum of feminine charm, plot, counter-plot, and triumph of virtue—attributes of general interest upon which fictional literature is usually based.

RESPICE FINEM (Barnstaple).—In common with rheumatism, obesity and gout, arterio-sclerosis probably owes its origin to impaired nutrition, arising from metabolic perversion.

R. M. O.—Our correspondent is well advised to concede the demand. The matter, after all, is not one of much moment, while it tends to convenience of arrangement, without a sacrifice of personal interest.

"THE INSTITUTE OF FACIAL PERFECTION."

WE are informed that Dr. F. Koch, of Berlin, did not read his paper on "Disfigured Noses and Their Correction" at the International Congress of Medicine, owing to the alleged fact, which was pointed out by *Truth*, and commented upon by the MEDICAL PRESS AND CIRCULAR of August 6th, 1913, that this gentleman was associated with the above institute, stated to be carried on by a Mr. C. H. Willi. It is gratifying to note that the executive of the Congress have acted promptly in the matter, but, as *Truth* remarks in the issue of August 20th, 1913, the omission of the paper "must have been a cruel disappointment to the pioneer of facial surgery!"

B. W. C.—Too much acrimony appears to us to have been introduced into the argument, and a settlement between two partners becomes impossible when this is the case. The plan might be adopted of securing the services of a mutual friend to act as arbitrator and relieve the friction which has unfortunately arisen.

M.D., F.R.C.S.—The lactate and bromide of zinc have been used with success in epilepsy in place of the usual bromide of potassium salt.

INQUIRENS.—The gastro-intestinal disturbance present in children during the summer months may be due to acidity of the succus entericus, to inhibition of the intestinal enzymes, to intestinal toxæmia from the absorption of products of decomposition, and to imperfection of the digestive cells.

OMEGA.—Raw apples are undoubtedly difficult of digestion, and should, for this reason, be forbidden for children, at all times. The indigestibility of uncooked apples is recognised by all authorities.

BIOGRAPHER (Edinburgh).—Regret we are unable to assist your enquiries in the direction refered to, but so far as memory serves us, we think you will find the best account of Dr. Archibald Cameron and the fate that eventually overtook him, in Sir Walter Scott's novel, "Redgauntlet." There would appear to be little doubt that he became the scapegoat of a revengeful government, and was executed under the law of treason.

Appointments.

CALDWELL, J. S., M.B., B.S.Edin., Certifying Surgeon under the Factory and Workshop Acts for the Beith District of the county of Ayr.

HOOD, THOMAS, M.R.C.S., L.R.C.P.Lond., has been appointed Principal Medical Officer in Southern Nigeria.

MANNING, FITZMAURICE, L.K.Q.C.P.Irel., Principal Medical Officer in Northern Nigeria.

ROBINSON, HARGREAVES, L.A.H.Dub., L.M.R.C.P.Irel., Clinical Assistant to St. Paul's Hospital for Skin and Genito-urinary Diseases.

SMITH, JOHN, M.D.Edin., M.R.C.S., L.R.C.P.Lond., Medical Referee under the Workmen's Compensation Act, 1906, for Fife and Kinross (Kirkcaldy District).

STEWART, J., Certifying Surgeon under the Factory and Workshop Acts for the Dufftown District of the county of Banff.

Vacancies.

Medical Officer wanted for Egypt. Salary £350 per annum, with extras. Apply, T. M., MEDICAL PRESS AND CIRCULAR, 29 Nassau Street, Dublin. (See advertisement.)

Monkstown Hospital, Co. Dublin.—Resident Medical Officer. Salary £40 and board. Immediate application to Hon. Secretary. (See advertisement.)

Hospital for Sick Children, London.—House Surgeon for six months. Honorarium £30, with board, residence, and washing. Forms of application of Secretary. (See advt.)

Oxford County Asylum, Littlemore, Assistant Medical Officer. Salary commencing at £150 per annum, with apartments, board, and washing. Applications to the Medical Superintendent.

Berkshire Education Committee.—Assistant School Medical Inspector. Salary of £300 and travelling expenses. Further particulars of W. C. F. Anderson, Education Secretary, Shire Hall, Reading.

Queen's University, Belfast.

Northampton County Asylum, Berrywood.—Junior Assistant Medical Officer. Salary commencing at £200, with board, lodging, and washing. Applications to Medical Superintendent.

Royal Sea Bathing Hospital for Surgical Tuberculosis, Margate.—Resident Surgeon. Salary £120 per annum, with board, residence, and laundry. Applications to the Secretary at the Offices, 13, Charing Cross, London, S.W.

London Fever Hospital, Liverpool Road, N.—Assistant Resident Medical Officer. Salary £150 per annum, with residence and board. Applications to the Secretary at the Hospital.

Certifying Factory Surgeon.—The Chief Inspector of Factories announces the following vacant appointment:—North Belfast (co. Antrim).

Births.

BIGGS.—On August 19th, at 10 Sudbrooke-road, Nightingale lane, S.W., the wife of George Nixon Biggs, M.B., B.S., of a son.

GOING.—On August 20th, at Erinagh, Littlehampton, Sussex, the wife of R. M. Going, F.R.C.S., of a son.

ILOTT.—On August 22nd, at Hamlegro, Bromley, Kent, the wife of Dr. Cyril H. Ilott, of a daughter

RODGERS.—On August 21st, at Hollins Lane, Winwick, Warrington to Dr. and Mrs. Fred Rodgers—a son.

SCOTT.—On August 19th, at Market Harborough, to Dr. and Mrs. C. T. Scott—a son.

Marriages.

BARKER—MORLEY.—On August 19th, at St. Botolph's, Cambridge, Lieutenant-Colonel Frederick Rowland Barker, M.B., R.A.M.C. (retired), of "Lyncourt," Chaucer Road, Worthing, and formerly of "The Mount," Aldershot, to Esther Clare, eldest daughter of Felix W. Morley, M.A., Mus.Bac., of 2 Harvey Road, Cambridge.

CATHCART—BOSTOCK.—On August 21st, at St. Chad's, Stafford, Edward Provan Cathcart, M.D., D.Sc., to Gertrude Dorman Bostock, M.B., B.Sc., second daughter of Henry Bostock, Esq., of The Oaklands, Stafford.

Deaths.

BUCHANAN.—On August 22nd, at Hampstead, the result of a gun accident, Major George Johnstone Buchanan, R.A.M.C.

FINCH.—On August 22nd, at a nursing home in London, Margaret, the wife of Herbert J. Finch, M.R.C.S. of Purton, Wilts.

MILLER.—On August 15th, at his residence, Finchley, London, N., Frederick M. Miller, M.R.C.S., L.R.C.P., aged 65 years.

NUNNELEY.—On August 21st, at 29 Royal Crescent, Bath, John Albert Nunneley, M.B., eldest son of the late Thomas Nunneley, F.R.C.S., of Leeds, and for 30 years Ophthalmic Surgeon at the Leeds Infirmary.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, SEPTEMBER 3, 1913. NO. 10.

NOTES AND COMMENTS.

The Prenatal Restaurant. THE announcement that a special restaurant for mothers-to-be has just been opened in New York will be welcomed by eugenists and the public alike. With the laudable object of keeping expectant mothers of the working classes in prime health by providing them with cheap and nourishing food, such a scheme should prove of the greatest value, and for its inception Miss A. Mabel Parker, of New York, may be highly commended. Both in France and Germany there exists State machinery for this purpose, and in Great Britain there are several private agencies at work with the same end in view. In the neighbourhood of London there is the Croydon Dining Room for Mothers, inaugurated under the auspices of the Women's League of Service "with the definite object of helping motherhood during the difficult time before and after confinement, and by properly feeding a woman beforehand, to enable her to bear a strong and healthy child." For the sum of twopence halfpenny a substantial midday meal of broth, meat and vegetables can be obtained. We understand that a similar "dining centre" is held at Hammersmith. It is well known that the character of the food taken by a pregnant woman reacts more or less directly upon the health and vitality of her offspring. A little wholesome instruction, simply imparted, either by popular lectures or the distribution of leaflets, would add to the undoubted utility of this beneficent enterprise.

Hysteria or Meningitis. THE occurrence of convulsions in infancy is such a frequent thing that unless often repeated or of exhausting severity, their significance is seldom likely to be over-estimated. Not so in the adult. The sudden onset of fits in a person of thirty years of age, previously healthy, would be sufficient in itself to arouse the greatest suspicion of intra-cranial disease. It is true that convulsions may sometimes occur in the course of some functional nervous malady, as in hysteria, or they may be symptomatic of certain forms of mental disorder. The medical attendant may be placed in an extremely awkward position if he fail to recognise the serious import of any symptom of disease, especially if the latter be a fatal one, and it is not always easy to say definitely whether any case with pronounced nervous manifestations be functional or organic. An unfortunate instance of this difficulty arose the other day at Leatherhead, where a medical practitioner, who was called to attend a working man suffering from convulsions, attributed the patient's condition to incipient mental unsoundness. The man died a few days afterwards, and the autopsy, made by two independent medical men, revealed recent meningitis, death being due to cardiac failure consequent upon the convulsions. Even if the true state of affairs had been correctly diagnosed during life, a fatal termination would, doubtless, still have been inevitable, but the consequence of the failure to appreciate the real gravity of the case comes as a grim warning to every practitioner in charge of cases of so-called functional nervous or mental disease.

French Drains. THE practical genius of the Anglo-Saxon could hardly be better illustrated than in his general sanitation. Although a great deal has been done by way of purifying rivers, abolishing slum areas, improving industrial conditions, and, in a word, housing all sorts and conditions of men in a scientifically good environment, much yet remains to be achieved in the United Kingdom. A holiday trip to the Continent should teach the English sanitarian a lesson of thankfulness that the good seed of the sanitary gospel has grown and flourished like a green fig-tree in his own land. Even in so advanced a country as France the contrast is striking. On a recent tour in the smaller towns and villages in the south of France, the writer was struck by the gross sanitary defects that were common. For instance, in one hotel in a small but fashionable spa there were three upper floors each having some sixty bedrooms. There was one closet on the staircase for each floor. Those on the two lower were of a modern flush-out type and were well supplied with water. The cistern on the top floor was defective. By manipulating the flushing apparatus it was sometimes possible to set it in action. As a rule, however, one was compelled to use a substitute in the shape of a pitcher of water, that is to say, when it happened to be full. Baths were absent in this hotel. In another hotel in the largest and finest spa in the district there was one old-fashioned pan closet, with weak and altogether inefficient water supply, situated at the bottom of a small well running up the middle of the building, covered in at the roof, and forming the outlet of a number of windows.

Malodorous France. THE sewage in our own country—in spite of the Pollution of Rivers Acts—is often turned into inland waters. It is not open to the British sanitarian, therefore, to throw stones at his Continental neighbours in this respect. In France, however, it appears to be the rule rather than the exception to discharge drains, wherever possible, into the nearest stream, or rivulet, pond, lake, or river. The beautiful Seine together with its tributaries is thus polluted at all parts of its course. Nor does the mischief end there. In many places crude sewage runs out of houses into the gutters of the streets, and the air of some of the most picturesque hamlets in France is heavy with malodorous vapours which rival the famous "forty stinks" of Cologne in their variety and pungency. Indeed, the ominous smell of sewage gas—unmistakable to the trained sanitarian—is practically universal in France wherever there are human habitations in mass or detail. Much of the evil might be done away with by a more stringent system of inspection and by the enforcement of existing laws. It seems unthinkable that so progressive a nation should permit its dwelling houses—let alone its hotels—to be provided with bad drains and defective, inefficient sanitary appliances. An inherent love of order and beauty is everywhere apparent, but it lacks the practical sanitary guidance which alone can place the health of a nation on a sound footing.

A Poetess on Surgery. The distinguished authoress of *Poems of Pleasure and Passion* has, in the current number of *Nash's Magazine*, thought fit to wage a violent paper warfare upon what she describes as "surgical hysteria," or "hysterical surgery," which she believes minimises the usefulness of both man and woman who choose to submit to "unnecessary operations" more than any other "combination of causes in any era of the world." Miss Ella Wheeler Wilcox certainly does give credit to orthopædic surgery, and even acknowledges that surgery can perform miracles of good, and that it is a blessing to the human race. It is when she discourses on the pelvic organs that her poetic licence knows no bounds, for she goes on to describe, in what seems dangerously near to hysterical prose, the evils resulting from people permitting themselves to be "hacked, unsexed, and deprived of natural organs when they might keep them." The grounds upon which she believes that women are "needlessly rendered barren," and the "appendix needlessly removed by surgeons" appear to rest upon no securer foundation than the personal knowledge of a few unsuccessful cases. Miss Wilcox is, of course, entitled to her opinions, but to say that physicians and surgeons "cause death or life-long invalidism for men and women by the score through unnecessary operations" is not only inconsistent, but it exceeds the limits even of poetic criticism. To hoist the authoress with her own petard, it is generally wise to "distrust that man (or woman) who tells you to distrust."

An Optician "Doctor." In our news column will be found the report of an inquest held at Croydon upon an infant of eight months, who died from sickness and diarrhœa, and who had been "treated" by a "Dr." Sparling, of Northcote Road. This gentleman, in his evidence, stated that he was an optician, and not a registered medical practitioner. He acknowledged having given medical advice and a prescription to the father of the child, who paid him 2s., believing him to be a qualified medical man. The child died the next day, and a registered medical practitioner was called with whom "Dr." Sparling was alleged to have formerly been in partnership. The evidence of the qualified practitioner was to the effect that Mr. Sparling had acted as his surgery attendant, seeing several patients and dispensing under supervision. In other words, it was the old story of the unqualified assistant over again. As the Coroner rightly remarked, Mr. Sparling had "brought himself within the clutches of the law by calling himself a doctor." No doubt the attention of the General Medical Council will be called to this case, which seems to be a plain instance of unqualified and unregistered practice. A further point of medico-legal interest is referred to by an esteemed correspondent, whose letter we publish elsewhere—namely, that no attempt appears to have been made to determine the actual cause of death by a *post-mortem* examination, the jury having been allowed to return the verdict of "Death from natural causes." In such cases the inquiry cannot be said to be complete, though it may be satisfying to the parties concerned.

LEADING ARTICLES.

ANAPHYLAXIS.

As a progressive science medicine presents an apparently inexhaustible field for research. Discoveries of far-reaching importance have been made in various directions within the past few years with such rapidity that it is difficult for the hard-working practitioner to keep abreast with the more practical advances in diagnosis and treatment. Fortunately, the modern tendency towards specialising, both in research and in practice, has relieved the pressure upon the private practitioner. At the same time, there are certain advances about which it is both desirable and necessary that he should be informed in order that he may do justice to himself and to his patients. A subject of that kind is anaphylaxis, the important discovery first described by Richet in February, 1902. The basis of this curious reaction was set forth in the statement that a substance which neither killed nor sickened a normal animal gave rise to intense and fatal effects in an animal which some time previously had been given a dose of the same substance. Anaphylaxis, in fact, is the opposite condition to protection (phylaxis). The discovery was due to some experiments into the toxic properties of certain marine animals. While endeavouring to determine the toxic dose it was found that when the animals had apparently recovered from a first injection after an interval of a few days a much smaller dose was rapidly fatal. English readers may now obtain authoritative information upon the whole subject from a translation of Professor Richet's work by Dr. J. Murray Bligh, Medical Registrar of the Liverpool Royal Infirmary (*a*). This systematic treatise is full of matter of fascinating interest. It shows, for instance, how previous investigators have been faced with the phenomena of anaphylaxis, the significance of which had escaped their vigilance. Behring, in 1893, found that guinea-pigs injected with antidiphtheritic toxin became in certain instances more intensely sensitive to that substance, but he did not consider the phenomenon either general among the injected animals nor common to all persons. Studying immunity particularly, he considered super-

---

(*a*) "Anaphylaxis." The University Press, London, Constable and Co., Ltd. 1913.

sensitivity a paradoxical reaction. Knois and Kitasato, working under his direction, showed that in some instances guinea-pigs died after doses 700 or 800 times weaker than the fatal dose. It remained, however, for Richet to state the general principles. The antigen that produces anaphylaxis is fairly definite. "Possibly some day," says Richet, "it will be found that a mild anaphylaxis follows the injection of crystalloids; but up to the present everything seems to prove that colloids alone are able to induce it; just as colloids alone are capable of producing the reaction of immunity." Crystalloids do not induce anaphylaxis, but colloids, almost without exception, are capable of inducing it. It is interesting to note, however, that although definitely crystallisable substances do not produce the reaction, yet certain drugs like quinine, antipyrin and iodoform are apparent exceptions, and in some predisposed persons inevitably lead to urticaria and anaphylactic sickness. The symptoms of anaphylaxis vary somewhat in various animals —a mild case being shown by pruritus, urticaria, local œdema, dyspnœa, fæcal and blood-stained bowel discharges, tachycardia and various nervous symptoms. The animal may recover suddenly after twenty to forty minutes or it may die in five or six hours. Or having recovered from anaphylactic shock it may die four or five days later of chronic anaphylaxis. In acute cases the onset is sudden, developing in one minute, sometimes in half that time, sometimes even during the second injection. The action appears to be due to what Richet calls an apotoxin acting upon the central nervous system. A period of incubation is required and a secondary dose administered before the lapse of the necessary interval has no effect. The first injection is described as preparatory; a certain time is required for the development of the toxic substance in the system, while the second proves the exciting injection. The tuberculin reaction is anaphylactic. The preparatory stage takes place in the tuberculous tissues, while the injected tuberculin excites a mild anaphylaxis. Many points raised in Richet's work are of great suggestive value. The minuteness of the preparatory dose was shown by Rosenau and Anderson to be even as small as 0.000,001 cc. of serum. Man is extremely sensitive to the anaphylactic reaction, and intravenous second injections invariably constitute an actual danger. There is a form of alimentary anaphylaxis, as, for instance, the acquired sensitiveness to horse serum shown by certain animals fed on horse-flesh. There can be little doubt that in Richet's brilliant discovery of anaphylaxis, medicine has added greatly to its resources. It is, of course, impossible to do more than outline the subject briefly within the limits of an article like the present, which is merely intended to draw the attention of busy practitioners to an important practical factor in their daily work. In a preface to Dr. Bligh's excellent translation, Dr. T. R. Bradshaw writes the following illuminating passage:—"During the past quarter of a century, however, the labours of the cytologist, the bacteriologist, and the biochemist have thrown a flood of light on the intimate processes of life, and the physician has not been slow to endeavour to turn to practical account the suggestions they have offered for his guidance."

CURRENT TOPICS.

Holiday Resorts and Insanitary Conditions.

At this time of year one sees platitudes appearing in the press about the benefits and delights of leaving the dust of cities and seeking the pure air of the country. Granting that in many ways the air of the country and seaside is purer than that of cities, and especially manufacturing cities, it is not so in respect of dust, except in isolated situations on solitary moorlands, where roads do not run and traffic is light. The country town or seaside holiday resort is far dirtier and dustier than the city, for the simple reason that it is not so well drained and watered. In the present day, with motors passing everywhere, disintegrating the road surface, and raising clouds of dust, even in the village with its single street, this nuisance is destructive of clothes and comfort; but in the seaside or country town, with its converging roads, dust is a serious menace to health. If the dust, swept up from the surface of the street by every gust of wind, or raised by each rushing motor in a suffocating, blinding fog, were composed of minute disintegrated particles of mineral matter only, the inhalation of it would be injurious to the lungs and provocative of inflammatory attacks of these mucous membranes, but, to a very large extent, dust being composed of human and animal excrement, of powdered offal, of fish, flesh and fowl, of human expectoration and bacilli of all sorts, it is evident that deposited on our food, or passing in quantities into our lungs, it must be a fruitful cause, an extensive propagator, of tuberculosis, pneumonia and other infectious diseases. Yet little or nothing is done by the sanitary authorities to abate this nuisance.

The Detection of Impurities in Food and Drink.

Some interesting information is contained in the report of the Government Chemist upon the work of the Government laboratory for the year ending March 31st, 1913, which was issued last week. With regard to so-called "temperance" drinks it may be noted that beverages of a non-alcoholic character are frequently sold as "cider" or under such names as "sparkling cider" and "champagne cider," with the added words "non-alcoholic" or "non-excisable," being, the Government Chemist says, mixtures of real cider with solutions of sugar and contain less than 2 per cent. of proof spirit. "But," he adds, "many non-alcoholic ciders, so called, are entirely free from fermented apple juice and are simply solutions of sugar which have been aerated, flavoured and coloured. . . . Six samples purchased as cider were found to be artificially prepared liquids." The percentage of alcohol present was determined in 356 samples of herb beers, beer substitutes, and temperance beverages. In 268 cases the alcohol did not exceed the legal limit of 2 per cent. of proof spirit, 63 samples contained between 2 and 3 per cent., 15 between 3 and 5 per cent., while ten samples described as ginger beer or herb beer contained proof spirit varying in amount from 5.7 per cent. to 11.5 per cent. So far as beer is concerned the 2,398 samples taken at retailers' premises showed practically the same percentage of dilution as the previous year. "Liqueur chocolates" are, apparently, not so innocent a sweetmeat as their name might imply. Of 23 samples tested six contained proof spirit ranging from 5 to 8 per cent., and in two cases the amounts were 23 and 27.4 per cent. In order to ensure that only genuine tea shall come into the country all consignments are examined at the port of entry, and doubtful samples are sent to the Government laboratory. Of the total number of samples submitted, 982, representing 73,355 pounds, were condemned as containing sand or other foreign matter and 15,491 lbs. additional were reported as unfit for human consumption. It is stated that there was, however, no evidence in any case of intentional adulteration and also that the quantity rejected, though large, is quite insignificant in relation to the total amount of tea imported, namely 359,000,000 lbs., an increase of 12,000,000 lbs. on the total of the previous year. The report also contains interesting information as to the use of preservatives in food products. Three years ago, boric acid, salicylic acid, and hydrogen peroxide were found together in several samples of cream and butter. This year no preservative other than boric acid was found in the samples tested. The total number of samples examined in the course of the year was 209,502, an increase of 14,332 on those of 1912. Such activity is ample proof of the care that is taken to ensure the purity of the food and drink that reach the consumers' table.

Effects of Exposure to the Sun's Rays.

Everyone is coming home from his holidays now. His friends greet him: "How brown you look!" implying that a convalescent dermatitis is an unfailing sign of exuberant health. It is a queer superstition. The actinic rays of the sun are rather harmful than otherwise, yet we all congratulate the man deeply, beautifully brown, as though there could not possibly be anything wrong with him, forgetting that many of the most sunburnt people we meet are sanatorium patients and that a bronzed skin and diseased adrenals have a distinct connection. Excessive exposure to the sun, from pseudæsthetic motives, does no real good. Besides its necrotic action on the skin, malaise, headache and a general upsetting of nervous control are not infrequently the total gain of the would-be fashionable no-hatters. Sunburn is a defensive effort of nature to interpose an opaque shield between the sun and the human organism. The burnt generations of the tropics have made this effort a hereditary trait, so that now the skins of the fathers are visited upon the children from the time of their birth. If an indiscriminate brunesence is a thing desirable and to be obtained at any cost, cosmetic colouring is better than chemical, and is much more convenient in a climate where at the shortest notice we may have to take a benighted walk under the midday sun.

School Medical Service.

Two explanatory circulars were issued last week by the Board of Education in connection with the new regulations with regard to grants for school medical service, prescribing the conditions under which they will be allotted. In cases where the Board is satisfied that medical inspection and treatment is satisfactory it will hand over to the authority one-half of the expense incurred. Where it is not satisfied it may reduce the grant or withhold it altogether. It is very gratifying that this step, which will be both a relief and a stimulus to the education authorities, has not been delayed. For the purpose of assessing grants in respect of the work of the school medical service, which is ancillary to, or associated with, medical treatment, the Board will be prepared to take into account ameliorative undertakings falling under any of the following heads, if carried out by the school medical officer or his staff, or under his direction or supervision: (a) The re-examination, after a suitable interval, of children found to be defective at the routine inspection. (b) The further examination at inspection clinics or elsewhere of children found to be defective at the routine inspection. (c) The examination at inspection clinics or elsewhere of "special" cases referred by school attendance officers, care committees, teachers, parents and others. (d) The "following up" of cases of defect by school nurses or health visitors by means of visits to the schools or the homes of the children. (e) The following up and after-care of cases of defect by children's care committees and other agencies working in co-operation with the school medical officer. Similarly, for the purpose of assessing grants in respect of medical treatment proper, the Board will take into account treatment falling under any of the following heads: (i) The treatment of minor ailments carried out by school nurses. (ii) The provision of spectacles, surgical or other appliances. (iii) Arrangements for medical or surgical treatment at hospitals, infirmaries, dispensaries, etc., or by private practitioners. (iv) Treatment at school clinics. The expenditure of money in this direction will be amply repaid by the increased physical welfare of the scholars.

"The Paths of Glory."

England is panicking about her athletes. She taught the world to play games, and now that she is no longer pre-eminent at every one, she prates about degeneration. The last Olympic meeting did it. America beat her. Now we have an influential committee sitting ponderously on the subject. America must be beaten at the high jump or the Empire is a thing of the past. American methods are decried and arrangements made to put them into practice immediately. The interesting thing is that America, who has lifted all the cups, and has even been honoured by a cartoon in *Punch* for so doing, is beginning to see that her cinder tracks are not paths of racial righteousness. To take an example, the Naval Academy at Annapolis has definitely barred contests involving extremes of strength expenditure. The four-mile rowing race is to be reduced to between one and two miles, and the quarter will be the longest track race allowed. These decisions are not the result of mere theorising, but because more deaths and enforced retirements through physical disability were found among officers who had been athletes than among the leaders of a simpler life. It is fairly obvious that an over-developed young man with a hypertrophied heart has less chance of long and healthy life than one of average symmetrical musculature. It is the story of the hare and the tortoise over again. The craving for results at all costs, with its postulated specialism, is the root of the matter. If we would go on as we were, instead of trying to adopt ephemeral American methods, whose authors are rapidly discarding them, it were better for us. We might adopt the sound paradox that the loss of athletic contests is a sign of progress, and that to win them points to degeneration.

The Use of Proprietary Medicines.

It is reported that the National Health Insurance Commission, Scotland, having been consulted as to whether proprietary medicines can property be prescribed by panel doctors and dispensed by panel chemists, have issued a circular stating that they are advised that, for the purpose of an Insurance Committee in the administration of medical benefit "Proprietary Medicines" are to be regarded as falling under two groups: (a) "Proprietary medicines" the composition of which is not publicly disclosed, but is alleged to be known only to the proprietors or manufacturers of the medicines. This group includes what are commonly known as "patent medicines" or "secret remedies." (b) "Proprietary medicines" the composition of which is published without reserve, though the preparation may be made up in a particular form, or called by a special name. The

Commissioners consider that in general it may be taken that preparations included in group (a) should not be prescribed for, or supplied to, insured persons. The Commissioners, on the other hand, consider that preparations included under group (b) should be supplied by chemists where ordered for insured persons or insurance service practitioners. The Commissioners assume, however, that practitioners will not order "Proprietary Medicines" under group (b) unless they look upon them as possessing recognised advantages over pharmacopœial or other well-known non-proprietary preparations of similar composition, and that they will, in prescribing, bear in mind that certain drugs which have special proprietary names figure also under other titles in the British Pharmaceutical Codex. These recommendations are entirely in accordance with the ethics of the medical profession, and such a pronouncement in respect of patent medicines is of value as constituting a definite official condemnation of the group of medicines known as "secret remedies." If the latter "should not be prescribed for, nor supplied to, insured persons," it may be assumed that their use should be equally prohibited for all sections of the community.

Compensation for Industrial Diseases.

The report of the Home Office Departmental Committee appointed to consider whether Cowpox, Dupuytren's Contraction, Clonic Spasm of the Eyelids, apart from Nystagmus and Writers' Cramp, can properly be added to the diseases enumerated in the third schedule of the Workmen's Compensation Act, 1906, has been recently issued as a Parliamentary White Paper [Cd. 6956]. The Committee consisted of Mr. Ellis Griffith, M.P. (chairman), Sir Thomas Clifford Allbutt, Judge Ruegg, and Dr. T. M. Legge. In their summary of recommendations the Committee express the opinion that (1) Cowpox and Dupuytren's Contraction should not be scheduled; (2) The word '"Nystagmus" added to the first column of the Schedule by the Order of May 22nd, 1907, should be replaced by the words "Miners' Nystagmus in miners or others (a disease most common among miners, of which oscillation of the eyeballs is the commonest but not invariably present objective sign)." The word "mining" should be retained in the second column; (3) The words "Writers' Cramp" should be added to the first column of the Schedule, the second column being left blank, and compensation for a single disablement should be payable in respect of not more than 12 months' incapacity in all. The Committee record their indebtedness to their secretary, Mr. Arthur Locke, of the Home Office, for the ability and courtesy with which he has discharged his duties.

Sir Jonathan Hutchinson's Museums.

It is one thing to found a hospital or a museum and another to provide adequately for its maintenance. According to the *Times*, the future of the educational museums, founded and equipped by the late Sir Jonathan Hutchinson, at Haslemere, Selby (Yorks), and 22, Chenies Street, London, is causing some concern to those whose privilege it has been to use them. In his will, the details of which have been recently published, Sir Jonathan leaves the museums to his trustees to dispose of as they may think best, expressing the desire that in such disposal they shall give effect to his known wishes—as expressed to them during his lifetime. There is, however, no other provision in the will for the future of the museums. In his lifetime Sir Jonathan spent on the museums and their equipment at least £30,000, and the Haslemere institution is insured for £10,000. At Haslemere there is a strong feeling that everything should be done to retain the museum for the town, and it is understood that the family are willing to hand it over to a responsible committee or body of trustees so that the museum may be placed on a permanent and public basis. The annual cost of maintenance on present lines is about £400, and an appeal will shortly be issued with the hope of securing this sum for five years at least, for it is recognised at Haslemere that if the forthcoming appeal is not adequately responded to the usefulness of the museum will either be restricted or the town will lose the institution altogether. The effort which is to be made to secure the museum for the town will have the support of the public men of the Haslemere district, and it is understood that members of the Hutchinson family are ready to co-operate. It was the hope of Sir Jonathan Hutchinson that when he died others would come forward to support the institution and continue the work he had begun. It is earnestly to be hoped that a speedy and adequate response will be made to the appeal, so that these wonderful collections of scientific treasures may be preserved as lasting memorials of their illustrious founder.

PERSONAL.

Major C. C. Cumming, R.A.M.C., has been appointed Clinical Pathologist at Malta.

Mr. W. R. Dunstan, M.B.Lond., D.P.H., has been appointed a School Medical Inspector under the Kent Education Committee.

Dr. Charles Macmaster has been appointed to succeed Dr. Dugald Revie as Medical Officer of Health for the Borough of Rattray.

Dr. Thos. Henry Peyton, M.A., M.D., D.P.H., T.C.D., has been appointed Chief Tuberculosis Officer to the County Coucil of Cheshire.

The staff of the Aberdeen Health Department have presented Professor Matthew Hay with a framed collection of their photographs, in commemoration of his completion of 25 years' service as Medical Officer of Health for that city.

Dr. Louis Sambon, who, it will be remembered, has twice been sent to Italy by the Pellagra Investigation Committee, has now left England on a third field exexpedition under the same committee's auspices, in order to study the disease in America and the West Indies.

Professor Francis Gotch, F.R.S., Waynflete Professor of Physiology at Oxford and formerly Holt Professor of Physiology at Liverpool, left estate of the gross value of £19,928, of which the net personalty has been sworn at £18,621. One of the executors is Sir Victor Horsley.

Dr. N. E. Roberts, Visiting Physician to the City Hospital, Parkhill, Liverpool, having resigned that office, the Port Sanitary and Hospitals Committee, in accepting the resignation, have placed upon record their high appreciation of the valuable services rendered by him during the long period of twenty years.

Dr. R. F. Vere Hodge, M.B.Cantab., has been elected to succeed the late Dr. W. G. Groves as Medical Officer of Health for the Woodford Urban District. Before making the appointment the council placed on record their deep regret at the death of the able and trusted adviser who had resided amongst them for upwards of 50 years.

CLINICAL LECTURE

ON

RADIUM IN THE TREATMENT OF MALIGNANT DISEASE. (*a*)

By ROBERT KNOX, M.D.,

Director, Electrical and Radio-Therapeutic Department, Cancer Hospital; Honorary Radiographer, King's College Hospital.

The use of radium in the treatment of malignant disease is one which possesses great interest for us all, because when first discovered great hopes were held out that at last we had a remedy which would really do something to help us in the treatment of these conditions. It was even hoped that we had a specific cure for cancer.

I shall endeavour to show you what can be done with radium in the treatment of cancer, and for convenience of description have divided my lecture into the following heads:—

(1) Physical properties of radium.
(2) Methods of application.
(3) Action of radium upon cancer cells.
(4) Method of ascertaining the extent of the disease.
(5) Selection of cases for radium treatment.
(6) Types of cases which have received benefit.
(7) Factors which are likely to influence the result of treatment.
(8) Improvements which are likely to lead to improvements in results.
(9) Practical conclusions.

The element radium was discovered in 1896 by Madame Curie in the form of a salt—radium bromide. It has since been separated in the pure state. It is a metal of the alkaline group, and is very similar to barium. It possesses chemical, physical, and biological properties.

The chemical properties do not directly concern us in our consideration of the therapeutics, but it is well to consider briefly the physical properties before we pass on to the biological effects upon tissues, as a familiarity with these characteristics is of great service to us when we have to deal with its therapeutic action.

Radium has the property of separating the particles of air into elements called "ions," which it charges with electricity. If radium is brought into proximity with a charged electroscope, it will be seen that the gold leaf quickly falls. This property of radium has been made use of in a method of measuring its activity.

The radiations from radium are very intense; a screen of zinc sulphide brought near to a small quantity of radium is lighted up brightly in a dark room, while brilliant fluorescence is produced on a screen of barium platino cyanide; and a photographic plate is quickly affected by it.

The emanations from radium are analogous to those of uranium, and consist of three types of rays:—

Alpha, easily absorbed.
Beta, penetrating.
Gamma, very penetrating.

The alpha rays are readily stopped by a thin sheet of paper.

The beta rays are sometimes described as soft and hard; the latter are capable of passing through several millimetres of lead.

The gamma rays are very penetrating, requiring several centimetres to stop their passage.

The proportion of these rays given off from a quantity of radium is relatively:—

Alpha.	Beta.	Gamma.
80	9	1

The action of radium on human tissues was accidentally discovered by Bécquerel in 1901. He carried a quantity of unprotected radium in one of his pockets for a time. A fortnight later a burn appeared on the skin.

The accidental discovery of the activity of radium quickly led to a number of experimental exposures, first on animals and later on human subjects, and the development of radium therapy was a natural sequence.

Wickham of Paris experimented largely with the new agent, and there is no doubt that the medical profession is greatly indebted to this pioneer in radium therapy, both for the valuable work he has carried out himself, and for having stimulated others to work on the subject.

Remarkable success followed the use of radium on superficial tissues of the skin, nævi, keloid, lupus, rodent ulcer, and later epithelioma, have yielded to its curative power.

Methods of Application.

(*a*) *Emanation.*—By (1) Inhalation alone or mixed with oxygen; (2) injection; (3) deposition of the active emanation upon metals, in glass tubes, on agar pads.

The first method, *i.e.*, inhalation, has had up to the present no practical value in the treatment of malignant disease.

By injection, the emanation may be injected into tissues in a saline solution. The solution takes up a very small percentage of the active gas, and is therefore hardly applicable for the type of case we are usually called upon to treat.

By the deposition of the active principles upon metals, etc., this opens up a large field of usefulness, and it is possible that in the future we may be able to make good use of this method in selected cases.

Experiments are being carried on by Mr. Phillips, the Honorary Physicist to the Hospital, on the absorption power of petroleum, and we hope to get a fairly large percentage of the emanation taken up by petroleum, giving us a very active preparation which may be useful, both for internal administration and for injection into the tissues; by the former method it is hoped that we will be able to introduce into the system a large quantity of radio-active matter, and, while hardly hoping to influence cancer and similar disease by such a method of use, we may look for results in diseases of the respiratory system. Dr. Bellingham Smith has shown that radium emanation in whatever form it is used is rapidly eliminated by the respiratory organs; so that a future field of usefulness for radium may lie in the treatment of respiratory diseases, phthisis, asthma, chronic bronchitis, etc.

(*b*) *External Applications.*—(1) Deposit of emanation upon flat surfaces—pads of agar agar. Application to the surface of a growth and ionisation of the particles into the deeper structures by the aid of a galvanic current. This should prove to be a useful method.

(2) Flat applicators containing the radium in a varnish. Useful in the treatment of rodent ulcer, superficial epithelioma, recurrent nodules of cancer, etc. It is chiefly the beta rays which are employed by this method. The percentage of radium in these applicators varies according to the purpose for which they are used.

(3) Radium contained in metal tubes which act as filters, and can be of the necessary thickness for particular purposes; several tubes may be arranged around a growth.

(*a*) A Post-Graduate Lecture delivered at the Cancer Hospital, Fulham, S.W.

(4) Tubes may be inserted into the various cavities of the body, such as the mouth, œsophagus, etc.

In treating a stricture of the œsophagus, a preliminary X-ray examination is necessary to locate the stricture, and to give some idea of the extent of the malignant growth. A bismuth cachet is swallowed by the patient, and when screened, may be seen passing down the œsophagus. Should there be obstruction the cachet will be found in the stricture. The exact situation of the obstruction can be determined before the radium tube is passed into it. Later, a radiograph will help us to ascertain if the tube occupies the correct position necessary to influence the growth.

(5) Radium tubes may be buried in the substance of a tumour, and left in situ for the time determined beforehand. It is important to have the tubes well surrounded by the growth in order to get the maximum effect of the radiations upon the new growth; the tubes should be placed at equal distances from one another to ensure an equal distribution of the radiations.

Action of Radium upon Tumour Cells.

The action is not purely a caustic one, though caustic effects can readily be produced if the exposure is too prolonged, or the filtration is not sufficient. In some growths we deliberately make use of the caustic action to produce necrosis of the mass in the hope that when the slough separates, the normal tissues will fill in the resulting ulcer.

Occasionally it may be observed that enlarged glands are reduced in size with hardly any skin reaction; even after repeated exposures to the same area of skin, nothing more than a slight erythema is produced, yet the enlarged glands situated at a much deeper level slowly diminish in size.

Malignant indurated ulcers will rapidly break down and heal under the action of radium.

The degree of action induced is dependent upon the method of application. The various degrees of tissue change depend upon the filtration employed and the length of the exposure. Thus—if necrosis of the growth is necessary, a thin filter would be used and a long exposure given. Here we are making use of the beta rays and gamma rays, but the percentage of the beta ray is so much greater than the gamma ray that for practical purposes we may assume that the action produced is largely due to the beta ray, that is provided the exposure is not unduly prolonged. Should it be necessary to act on a deeper structure and at the same time protect the skin from such action, a thick filter of platinum or lead is used. Here the beta rays are almost entirely cut out, and the action is due to the gamma rays.

Two millimetres of platinum or four of lead are sufficient to cut off all but the hardest of the beta rays, while the gamma ray is unaltered. The filters containing the radium are enclosed in a rubber tube to prevent the secondary radiation induced in the platinum by the radium rays damaging the superficial structures. If the exposure is to be a long one, further protection can be secured by using an inch or more of lint or gamgee tissue.

In this way we can control the exposure so that we get nearly the pure gamma ray effect. This enables us to get an action upon the deep-seated parts.

It has been claimed that radium possesses a "selective action" on cancer cells. While admitting that it undoubtedly appears to act on such cells, it must be stated that the word "selective" is badly used in this sense. Radium possesses an action on all living cells in a varying degree, according to the resistance of the particular cell in question. Thus, young actively growing cells are more readily influenced than matured ones. The cells of a new growth approximate in structure and power of resistance to the actively growing cells of a tissue. In this way it is conceivable that the cancer cell is influenced should it at the time of exposure be attacked comparatively early in its life cycle. Should the cancer cells be of a stronger or more vigorous type, it is conceivable that the action of the radium may be a stimulating one and instead of a decrease in vigour of a particular cell, we may find an increase in activity, and a consequent increase in the size of a tumour. It is a fact that some cases of cancer increase in size at a quicker rate after radium has been applied. Some types of cancer are more amenable to radium treatment than others.

In addition to the action upon the cancer cell itself, radium acts upon all the tissues composing the growth and surrounding tissues. There is a general stimulation of the healthy tissues as a result of a radium treatment, so long as the exposure is not excessive. If it should be excessive, the action is apt to produce a caustic and ulcerative effect which leads to a local death of the tumour and a portion of the tissues around it. This may sometimes be desirable.

When the effect upon the healthy tissues is confined to a stimulation, we expect to find an increase of fibrous tissue formation which shuts off the cancer tissue from its blood supply and causes the atrophy of such cells. The reparative power of the normal tissues is strengthened, enabling them to cope with the invading cells and lead to their destruction.

These changes can be seen in sections removed from cases undergoing treatment.

The changes induced in malignant growths by the action of radium and similar agents are, so far as we can see, indistinguishable from the degenerative changes seen in cases of growth which have received no treatment; but this important point must be insisted upon; that the percentage of cases in which we see these changes is much larger in the group of cases treated by radiations than in the group which has received no treatment.

It must be admitted that occasionally we see a case of untreated cancer diminish in size, and, in a very small percentage, ultimately disappear. During the treatment of cancer by radiations, it is by no means uncommon in a fairly large percentage of our cases to see a marked diminution in size produced. In a smaller percentage we do see the growth disappear—at all events for a time.

The local disappearance of a growth is not a cure. The disease may have, and, in the majority of cases, undoubtedly has, extended to other parts of the body.

Consequently no case can be said to have been cured until we have given the deeper ramifications of the growth sufficient time in which to develop and manifest their presence. It is therefore important that before we treat the local condition a search be made for secondary deposits.

From the point of view of prognosis, this is a most important matter.

What means do we possess of showing the secondary spread of cancer?

The first important point is to remember the distribution of the lymphatics draining the area in which the growth shows itself. Improvements in radiographic *technique* enable us to carefully examine the thorax and other parts for secondary deposits. These may be found in the mediastinum, pleura, and lungs

A photograph which I show you is from a man, 24 years of age, who came for the treatment of a growth of the lower jaw. That in itself was a serious condition to deal with, because at that age the progress of a new growth is rapid and exceedingly difficult to check. An examination of the thorax revealed a large secondary growth in the right lung. One has to treat such a case, but the result can easily be foretold.

In another case which came for treatment, a parotid tumour had been operated upon on several occasions, and latterly the condition had practically disappeared under radium; the patient appeared to be in good health, but had lost a great deal of weight in a few months. In addition he complained of occasional attacks of dyspnœa of short duration. A radiograph revealed the condition shown on the plate; both lungs literally riddled with secondary growths.

A woman, æt. 55, had her left breast removed. She came for prophylactic X-ray treatment. The scar was free from secondary deposits. She, however, complained of a deep-seated pain at the upper end of the sternum. Secondary deposits were discovered in the anterior mediastinum.

One more interesting case may be quoted. A patient who had her left breast removed about a year ago came for the treatment of recurrent growth in the scar, axilla, and supraclavicular region on the left side. These are quite evident, and are undergoing treatment by radium. For several months the patient has complained of a severe pain on the right side of the sternum. It is deep-seated and of a gnawing type. Several screen examinations and radiographs failed to reveal the presence of a definite recurrence on the right side. She has, however, been carefully watched, and a few days ago another radiograph revealed the cause of her pain. A well marked secondary nodule can be plainly seen on the plate which I show you. In addition, on the left side, a supraclavicular gland is seen.

This case is most instructive. It illustrates a point I am rather anxious to emphasise, namely, that regular examinations at intervals should be carried out on all patients undergoing treatment, either curative, palliative, or prophylactic.

Selection of Cases for Radium Treatment.

This is probably the most important point in the whole question of the value of radium therapy.

What type of case responds best to radium?

It is unfortunate that the class of case which offers the best results in radium treatment should also hold out the best promise of success by operation.

The earlier we can treat a case of malignant disease the surer can we be of the result of such treatment. It is really unfortunate that such should be the case, because at the very outset we must decide between the two.

In the present state of our knowledge of radium and its effects upon new growth, we have no hesitation in saying that the choice must be given to early operation. The reason for such a statement is that we cannot tell when a case is going to do well under radium, and valuable time may therefore be lost if we use the latter, and an operation may in the end be considered necessary.

Two cases of the same disease, and to all appearances precisely similar, may react quite differently to radium. Further, should the growth not promptly yield to the treatment, it may happen that the stimulation of the tissues composing the growth leads to a rapid extension of the disease, secondary nodules appear at the periphery of the tumour and grow rapidly, or metastases may appear quickly in deeper parts. Even when to all appearances the growth has disappeared, sooner or later recurrences may follow, and this after what at the time seemed adequate prophylactic treatment.

To take examples, rodent ulcers when treated early are particularly amenable to radium. They remain healed for considerable intervals, yet in the end a small recurrence appears at the periphery of the ulcer, and if not promptly dealt with this may spread. Repeated recurrences have frequently to be dealt with in the same patient.

Admitting that in every early case of malignant disease operative measures should come first, there are some conditions when radium should have second choice :—

(1) The patient may refuse operation. Radium should then be the remedy of choice; though treatment in early cases may lead to a disappearance of the growth.

(2) Or the patient may not be in a suitable condition for operation. Again radium may be found useful.

(3) Or it may be that the operation must be so radical that the risk to life is great. Radium should here be given careful consideration as a remedial agent.

(4) Inoperable cases of malignant disease are generally handed over for radium treatment. Many of these cases are hopeless from a curative point of view. Here radium will relieve pain, diminish discharges, check hæmorrhages, and frequently heal up ulcers of considerable size.

The group of inoperable cases may be divided into two classes.

(*a*) Advanced cases of malignant disease, where it is obviously impossible to hope to do anything beyond the relief of the pain and other distressing symptoms which accompany the condition.

This relief is sometimes a marked feature in radium treatment. Discharges may be lessened, and where hæmorrhage is a feature in the case, especially if it be a general oozing from the growth and surrounding tissues, a sufficient exposure to the action of radium will lead to a cessation of the bleeding. Failing the prospect of achieving either of these results, such advanced cases should be left severely alone, as their treatment by radium can only bring discredit upon the remedy used.

(*b*) Less advanced cases, where there may be a prospect of inducing degenerative changes in the tumour mass which will lead to a diminution in size and possibly bring the case within the range of operative treatment.

This may be accomplished in a percentage of the cases we have to treat. I shall demonstrate to you later a number of cases where I think this end has been reached.

The method of treatment adopted must be through full exposures given at regular intervals and the patient kept under observation. The treatment may be external or, in selected cases, tubes of radium may be buried in the substance of the growth.

Inoperable tumours of the breast come under this heading.

Surgical methods may profitably be combined with the use of radium, and partial operations are a great help to the radium therapist, as it is quite rational to remove as much of the tumour as is possible in order to facilitate the use of radium. To take an example, a large fungating necrotic tumour of the breast is not likely to yield to radium treatment alone, while if the surgeon removes as much of the growth as possible, then radium may be employed on the portions of the tumour left behind. Secondary deposits in the glands and areas drained by the lymphatics may be vigorously treated by radium, and if a diminution in size is brought about, these may be removed at a subsequent operation. Life may be rendered more tolerable and undoubtedly prolonged by such measures.

Several such cases treated by radium and X-rays have shown marked improvement. Enlarged malignant glands have been successfully removed after reduction in size following upon radiation treatment.

While admitting the claims of operative measures in dealing with early cases of malignant disease, and with no intention of pushing the claims of radium, I should like to quote two cases which were in my own, and in the opinions of several surgeons, operable, but the patients refused operation and were treated by radium.

A case of endothelioma of the soft palate with a secondary gland in the neck was operated upon for the removal of the gland. A portion of the growth in the palate removed for microscopic examination showed it to be a slowly growing endothelioma. The palate growth was of considerable size; under radium treatment it slowly subsided and practically disappeared. The case was treated nearly three years ago; to-day the patient is in hospital for a recurrence of the growth in the posterior aspect of the soft palate. She has been quite comfortable during the time that has elapsed since she was first treated. I have no doubt she will derive benefit from further treatment by radium.

A gentleman, about 60 years of age, was referred to me for treatment of a growth in the right tonsil involving the soft palate and uvula. He was seen by several surgeons, but refused to have an operation performed. A section removed for examination showed it to be an epithelioma. A gland removed from the left side of the neck was inflammatory in character, a number of enlarged glands were present on both sides of the neck. Under radium treatment the growth slowly diminished in size, a portion removed later still contained malignant cells which were changed in character and surrounded by inflammatory products. The glands in the neck slowly subsided. To-day the patient is perfectly well and free from recurrence.

Types of Cases which have Received Benefit from Radium Treatment.

(1) *Rodent Ulcer.*—Early cases are readily influenced by treatment. They quickly heal, prophylactic doses should be given after the ulcer has healed. If the condition is quite superficial, the filtration need not be great. The beta ray action appears to exercise a profound change in these cases. After healing has taken place, filtered doses should be used to reach the deeper parts. Even after thorough prophylactic treatment recurrences are apt to follow at longer or shorter intervals. These frequently respond to further treatment. All cases treated should be kept under observation for a considerable time in order that an early stage of the recurrence may be observed and promptly treated.

When the ulcer is large and involves bone and cartilage the prospect of a cure is not so good. Most complete and powerful dosage may fail to check the progress of the disease. These cases may even be stimulated by radium treatment, and increase rapidly in size. In such cases it is better to combine surgical measures such as scraping or excision with radium treatment. Several cases so treated have healed and remained well.

(2) *Epithelioma.*—Growths in the skin are sometimes successfully treated by radium. Here again the excision of the growth and after-treatment by radium commends itself as a rational method of cure.

When the mucous membrane is involved greater difficulty is experienced in influencing the growth favourably. Some growths of the mucous membrane of the mouth and pharynx are hardly influenced by radium.

Epitheliomata which have healed may break down later and grow rapidly. Secondary involvement of glands must be treated as well as the primary growth.

(3) *Sarcoma.*—The round-celled variety seems to be the type of growth which is most readily influenced by radium. Large tumours may gradually diminish in size, smaller growths disappear, while secondary glands also clear up when treated. The spindle celled variety is not so readily dealt with, possibly because it is a more active type of growth. When the mediastinum is involved, exposures may be made over the sternum and ribs in the hope that the disease may be checked.

(4) *Cancer of the breast.*—Primary and recurrent.

This class forms a large percentage of the cases which are sent for radium treatment.

Secondary deposits may be met with in the glands of the axillary and supra-clavicular regions. These should be treated at the same time as the primary growth.

Secondary deposits in the cartilage of the ribs or sternum may also require treatment. Prolonged exposures to large quantities of well filtered radium have in several instances led to a diminution in the size of the growth.

(5) *Cancer of the œsophagus* has been treated with a beneficial result for a time. Patients so treated have gained weight and retained the use of the œsophagus up to the time they died of secondary growth in the mediastinum.

(6) *Cancer of the rectum.*—Symptoms may be relieved for a time. The radium must be passed into the stricture, otherwise it may act as an irritant to the healthy mucous membrane and increase of distressing symptoms so common in this situation.

(7) *Cancer of the cervix uteri* may also receive benefit from radium treatment. Hæmorrhage, and discharge are lessened and great relief of pain is a frequent result of treatment.

(8) *Cancer of the body of the uterus.*

(9) *Cancer of the bladder.*—If a tube can be introduced into the bladder and brought in contact with the growth, relief may be obtained.

Factors which are Likely to Influence the Result of Treatment.

In routine treatment by radium, the following factors should always be kept in mind, as a full consideration of all in each case will help us to foretell the degree of action and the result likely to follow from treatment.

(*a*) Type of growth and condition of patient.
(*b*) Situation of the tumour, size, etc.
(*c*) The quantity of radium used.
(*d*) The filtration employed.
(*e*) The duration and frequency of the exposure.

What factors are likely to lead to an improvement in the results at present obtainable by radium in the treatment of malignant disease?

(*a*) Larger quantities of radium may be used. Up to the present, the largest quantity used has been about one gramme of pure radium salt. Far-reaching effects may be produced by such a treatment, especially if the filtration is great and the exposure prolonged; yet, even with such a dose, the result in one or two cases has been a temporary benefit only. The type of case so treated has been a deep-seated growth which could only be acted on by the very penetrating rays.

For surface lesions, the increased dosage may have a speedier effect which should help to prevent the spread of the growth to deeper structures if it can be efficiently checked.

(*b*) A more thorough knowledge of the physical properties of radium may enable us to select for particular cases the quality of radiations likely to influence the cell metabolism.

(*c*) Improvements in the *technique.*

Up to the present it must be admitted that the *technique* has been more or less faulty. A knowledge of the various thicknesses of filters may help us to get speedier results. It may be that the use of the beta rays in some cases would lead to better results. Similarly the alpha rays, which up to the present have been little used, may in the future be found to exercise an inhibitory effect upon morbid processes when they are brought into contact with the cells of a growth. The difficulty has been to apply them at all. The radio-active waters at present in use do not appear to have any influence on cancer cells when administered by the mouth.

It may be possible to deposit the active principles of the radium emanations in such a way that we can utilise them either by direct application or by ionisation with the aid of a galvanic current, or a combination of radiations may be helpful; in several cases radium and X-rays appear to have hastened reparative processes.

It is possible that some of the effects we notice in cases so treated may be due to secondary radiations produced in the structures composing the growth which exercise a physiological action.

Some such general action appears to take place, because it is quite a common occurrence for patients so treated to improve in general health Further, the employment of radiations in any form leads to a constitutional disturbance which we designate as re-action. This varies in time of onset according to the dosage.

After a given time a period of depression sets in. It is most probably due to a change set up in the growth which leads to the liberation of toxines. The presence of these bodies in the circulation sets up the constitutional effects. If they are excessive, the condition of the patient may be rendered serious. This form of toxæmia is met with when large rectal growths are treated. It is possible to make the condition of the patient much worse if care is not taken to regulate the dose.

Up to the present, the treatment of malignant disease by radium and other radio-active bodies has been a purely local one. Consequently it cannot be regarded as a specific method of treatment.

Under what conditions are they ever likely to become so?

This question suggests possibilities which are at present being investigated.

The endeavour must be to procure a substance, radio-active or not, which, when introduced into the general circulation, will influence morbid processes in the tissues.

It may be possible to use a substance which when treated locally by radium, X-rays, or other agents capable of exciting the secondary radiations of such substances, will benefit the tissues.

Up to the present the best we have been able to do has been by local stimulation to produce secondary radiations from the tissues, blood and lymph, in the deposits of cancer.

When the secondary radiation value of these tissues is better known, and when we know which particular radiation acting upon them will give us their maximum value, then we may hope to improve our results.

The practical conclusions we can deduce from our consideration of the value of radium in the treatment of malignant diseases are:—

(1) In all cases of early cancer the operative method is undoubtedly the best; it is quicker, safer, and offers the best prospect of a cure.

(2) Radium is a useful adjunct to the treatment of all cases, first as a prophylactic after operation, and, failing operation, the next best method we possess. It must, however, be stated that X-rays are in selected cases quite as useful as radium.

(3) In cases which refuse operation or are for other reasons not suitable for operation, radium is a useful remedy.

(4) In inoperable cases, radium may help to render the case operable; and, failing that. is undoubtedly useful as a palliative measure.

Note.—The lecture was illustrated by a demonstration of the action of radium radiations on an electroscope, illustrating the action of filters in obstructing the rays. A demonstration of the emanation from radium in a flask coated with zinc sulphide. Mr. Phillips, the Honorary Physicist, demonstrated these points.

ORIGINAL PAPERS.

THE INFLUENCE OF THE DUCTLESS GLANDS UPON DEVELOPMENT. (a)

By HASTINGS GILFORD, F.R.C.S.,

Consulting Surgeon to the Reading Dispensary and Ringwood Sanatorium.

No one who attempts to assimilate the information upon the ductless glands which has been collected by Sajous, by Swale Vincent, by Biedl, by Cushing, or goes to the sources of their supply but must be struck with the growing importance of the subject. At the same time, it becomes evident that this information cannot as yet be brought to a focus. It tends to run along different lines—lines which are often divergent, sometimes parallel, and seldom meet. Two kinds of research are being conducted upon the subject, one clinical and pathological, the other experimental. The former is scanty but eminently suggestive; the latter copious, ingenious, and interesting. Experiment has led to the discovery of the hormones, has thrown light upon the nature of the changes wrought by the deficiency of secretions, and has furnished us with some valuable pharmacological agents. Indeed, the by-products of the investigation are perhaps even more valuable than those which have been attained as the main object of pursuit. We seem driven to the conclusion that information as to the uses of the ductless glands must still be gathered mainly from clinical, surgical, and *post-mortem* study. We must apparently expect very little direct practical result from investigations of the normal, but depend largely upon those of departures from the normal.

The subject we deal with is one of correlation, not so much of correlation itself as of the excitement or depression of correlation.

The whole series of correlations which terminate in the perfect balance and adjustment of organs of the vertebrate in his prime are probably in the first place mechanically induced. At any rate it has been shown by Bataillon (1) that the unfertilised egg of a frog may start on a career and continue up to the tadpole stage by means of needle puncture alone. In all probability, therefore, it is the mere mechanical penetration of the germ cell by the sperm cell which is the stimulus for the first correlations in all vertebrates, the fusion of sperm with germ afterwards supplying that blend of characters which constitutes complete fertilisation. There now comes a period of development in which there are as yet no ductless glands, when, as in plants, the necessary stimulus to correlation is both simple and direct. Here we see the beginning of two forms of co-ordinating stimuli. The contact of cell with cell and the conduction of primitive nervous impulses leads ultimately to that elaborate nervous mechanism which is responsible for the awakening of many of the correlations which take place in the post-natal human being. So also for a time there must exist in the primitive embryo some simple secretive mechanism which later on will be gradually segregated into organs and become ductless glands devoted to the production of hormones to excite and harmonise the action of widely separated organs. May it be suggested that this primitive faculty of cells is never lost, that in after life the ductless glands do not monopolise the power of chemical stimuli to correlation, but that all tissues possess some degree of the same property?

Local Correlations.

It may be in some such way as this that we account for local correlations. Thus when a segment of a long bone is destroyed in infancy the growth of muscle, fat, vessels, nerves, and skin does not continue as on a sound limb. On the contrary, a considerable degree of adjustment takes place. The growth of the soft parts is manifestly accommodated to the needs of the shortened bone. Moreover, such correlation is not solely the outcome of disuse, for we see a similar process at work in the limbs of the rickety and the achondroplasic. Local adjustments of this sort vary greatly in their completeness. Thus in some achondroplasics the soft tissues of the limbs are obviously disproportionate, the muscles and fat bulging in ungainly lumps, and the redundant skin being pleated into folds. But, as a rule the accommodation is much more perfect, and at its best even the trunk seems to be reduced in length to fit in with the altered circumstances, while its contained organs are moulded on a smaller pattern. It is true that achondroplasia is one of the disorders which has been attributed to the deficiency of pituitary secretion. But so far this relation is no more than suspected. The evidence is as yet so meagre that we are hardly justified in classifying achondroplasia either as a pituitary or as a sexual disorder. On the other hand, the locality and nature of the changes seem to point pretty conclusively to the skeleton as the prime seat of the disturbance.

Another disorder of early ascending development which appears to point to correlating influences apart from the ductless glands is microcephaly. In microcephaly there is marked stunting of growth in general. Nobody has as yet suggested that this stunting results from any hormonic deficiency. Neither does it seem probable that it is the result of trophic changes of nervous origin. It seems much more likely that we have here another example of the adaptation of the body at large to the contingencies of a defective organ. Such adaptation is variable and may be very defective. Thus the correlation of the growth of the calvarium to that of the microcephalic brain is sometimes decidedly inadequate. Bone seems to be formed as if for the protection of a normal brain, with the result that the ossifying membrane is pleated and the parietal bones fuse at the vertex and become heaped up into a prominent ridge. Soft tissues, moreover, may be correspondingly redundant so that the scalp fits badly. hanging loosely in folds, as if a few sizes too large for the brain it encases. The body and limbs, moreover, though actually stunted, are relatively too big, with the result that the brain tissue is not employed to the best advantage, that which should be devoted to the purposes of intellect being diverted to satisfy the less important requirements of the body and limbs. But sometimes the adjustment is much more complete, the body being smaller and the intelligence less defective. On rare occasions with a brain of microcephalic proportions the growth of the body is so adjusted that the intelligence is very little affected. Of such cases a good example was furnished by the celebrated dwarf General Mite, who at the age of 15 possessed a brain measuring no more than 41.5 cm. in circumference and yet showed a fair amount of intelligence. There can be no reasonable doubt that the retention of intelligence, despite this extraordinary smallness of brain, was due to the fact that he was only 82.4 cm. in height and 6.5 kg. in weight. Another instance of correlation of a similar character was the dwarf Edouard Placereau, about whose case there was a discussion in Paris in 1881. When 14 years old he was only 93 cm. high and the circumference of his head was only 39 cm.

(a) Paper read at the International Congress of Medicine, London, 1913.

The object I have before me is to emphasise the doctrine, first brought forward by Bernard, that while the ductless glands serve an important purpose in the correlations of the body they are only a part of the machinery of adjustment. For rapid adjustments the nervous system comes into play and for slower we have not only the ductless glands to consider but also that primitive capacity for adjustment which is inherent in the tissues of all parts of the body.

The Disorders of the Ductless Glands.

Out of the fog which at present obscures the subject now under discussion we seem to see gradually emerging a few clinical types of disease, the outcome of pathological changes in the different ductless glands. They are as yet very ill-defined, owing partly to the overlapping of their symptoms, partly to the variability of the effects produced by similar lesions, and, it may be, partly to the influence of other factors, such as those to which reference has just been made. Yet we are not without hope that we are on the right tack for the solution of the problem before us. It is right that we should co-ordinate our knowledge and formulate our theories even though all the time we are conscious that our knowledge and our theories are fallacious. I have therefore adopted the usual grouping of these diseases if only for the purpose of showing the difficulties with which any such classification is beset.

1. *The Thyroid Group.*—Largely owing to the superficial position of the thyroid gland, to its singleness, to its simplicity of structure and of function, we know more of its effect upon development than we do of any other ductless gland. This being the case we need hardly concern ourselves with its diseases except for the help they afford to the understanding of other groups. *Defective* action of the thyroid gland, as shown in cretinism and in myxœdema, makes us realise that the inaction of a gland at one stage of development may bring about results superficially different from those induced at another stage of development. In contrasting myxœdema with Graves's disease we see moreover that the *excessive* action of a gland does not necessarily produce symptoms opposed to those which result from defective action. For example, the conspicuous infantilism of cretinism cannot be contrasted with any premature senile decay in Graves's disease. Though the one is a dwarf the other is not a giant. The sexual system is in abeyance in the one but is not exaggerated in the other: neither is there any orbital change in cretinism opposed to the bulging eyes of Graves's disease. Lastly, the manifestly diminished function of the sex organs in cretinism is not balanced by any undue sexual exaltation in Graves's disease. At the same time we are convinced that the one malady is the antithesis of the other. Metabolism flares up in Graves's disease and smoulders in cretinism. Obviously under normal circumstances the thyroid presides over metabolism, and its effects upon different parts of the body are fairly equal. As for the para-thyroids we cannot as yet say whether they represent only undeveloped thyroid tissue or are possessed of some function subsiding to that of the thyroid.

The Lymphatic System.

The thymus, spleen, bone marrow, lymph glands and those outlying patches of lymph tissue to which Dr. Pye-Smith has given the name of lympharia are, like all other organs, liable to the extremes of growth and development. When *overgrown* we have the condition termed lymphatism. Lymphatic tissue. being relatively at its acme of functional activity during infancy and childhood is also then most liable to loss of control in the direction of excess. An infant in a state of lymphatism in its most characteristic form is fat and pale and stolid, though the intake of food may be under rather than over the average. If we can judge from the way in which lymph tissue increases in hybernation its office is one of conservation of tissue change. It apparently inhibits in some degree the action of the thyroid, the pars anterior of the pituitary gland and the sex organs.

Destruction of large tracts of the lymph system by degeneration as in Hodgkin's disease, gives rise to a syndrome in which, apart from the glandular enlargement, emaciation and debility are conspicuous. These may be contrasted with the fatness of lymphatism and with its occasional increase in muscular growth.

The Sexual System.

As in the case of the lymph system all attempts to influence growth or development by extracts from the sex glands have failed. Though the experiments of Berthold in 1849 strongly suggest that the sex glands act upon development through the medium of a secretion, the point cannot as yet be termed an established fact at any rate in all cases in which sex correlations are concerned. Perhaps one of the greatest of therapeutical triumphs is the extraordinary improvement which takes place in osteomalacia as the result of removal of the ovaries. Yet there is no evidence of any alteration in the ovaries themselves to account for osteomalacia nor to explain the good that is done by their removal. Moreover, we are not in a position to conclude that the series of changes which takes place at puberty is solely the result of the pouring out of secretion from the sex glands, nor are we justified in assuming that the changes at the menopause are solely due to the withdrawal of that secretion. The occasional presence of heterologous sex characters in hermaphroditism is very difficult to account for by the theory of hormones. Further, changes in the sex organs of plants are collelated with changes in other parts of the plant organism without the intervention of a hormone. If we assume that such hormones are essential we have still the problem to solve as to what initiates the changes in the glands which lead to their secretion. All that we are justified in saying is that a series of correlations become active at puberty and sink into a state of inaction at the menopause, and that the working of this machinery is apparently partly dependent upon the presence of a secretion from the ovaries or testes.

Pituitary System.

The fact that the pituitary gland is a double organ with satellites so greatly adds to the difficulty of estimating the effect of its diseases that it is at present possible to do hardly more than conjecture its influences upon normal growth and development. The trend of opinion is to regard acromegaly as the expression of excessive action of the pituitary followed by defective action. We therefore best arrive at our rough estimate of the relations of the pituitary gland to acromegaly by first noting what takes place when the gland is *defective*. And here we seem to get great help from experimental research, for Cushing and his school have shown very clearly that certain symptoms arise as the result of partial removal of the pituitary. (2) These symptoms are recognised as corresponding with those which are now widely known under the name of Fröhlich's syndrome. There is a state of moderate infantilism, the whole body being retarded in its development; inhibition of the sex organs; general obesity; some psychic and cerebral disturbance, and an increased tolerance for carbohydrates. It is true that Aschner (3) does not find the pituitary gland essential to life and that Handelsmann and Horsley's (4) cases show that such removal has none of the lethal or even deleterious effects ascribed by Cushing. But this negative evidence is at present overwhelmed by the positive and awaits confirmation. Then cases are recorded in which with infantilism, pronounced sexual defect and obesity there is no direct evidence of aplasia or disease of the pituitary gland. Some of these probably fall under the head of primary sex infantilism or feminism; others are examples of ateleiosis, such as will be referred to presently. We are only justified in regarding a case as one of Fröhlich's disease when there is definite and direct indication of the presence of a pituitary tumour or of hypopituitarism. Among the many puzzles which confront us in dealing with the disease of the ductless glands is to account for the fact that when portions of the hypophysis have been removed by operation or by injury, as in Madelung's classical case, the remaining portion, as well as the accessory glands, do not increase in size to make up for the deficiency.

If we adopt Cushing's view that acromegaly is due first to *excessive* and then to defective action of the pituitary gland we have great difficulty in accounting for those cases in which there is weakness and loss of sexual power from the beginning. Thus Prof. Schloffer (5) reports a case in which acromegaly, associated with symptoms of cerebral tumour, was treated by operation. Part of the pituitary was removed and found to be in a condition of simple hyperplasia. Yet all the symptoms were such as we associate with pituitary hypoplasia. Moreover, they were unmistakably improved by the operation.

Among the disorders attributed to defective action of the hypophysis are ateleiosis and progeria.

Ateleiosis is an essential infantilism of Brissaud's type. It has a striking individuality, and is clearly to be distinguished from myxœdème frustré. It is not amenable to treatment by thyroid extract, and sometimes occurs in two or more members of the same family, but not in association with cretinism or myxœdema. There are two forms, the asexual, in which none of the primary or secondary sexual characters is developed, and the sexual, in which, usually after some delay, the sexual organs develop, so that in a few cases these ateleiotics have actually borne children. I have myself seen one such case in which the intimate relation between the two forms of ateleiosis was proved by the fact that the father was of the sexual variety and the son of the asexual. In a case of ateleiosis, fully described by Arnold Paltauf, there was a tumour of the pituitary body. On the other hand in Schaaffhausen's case, in a skeleton in the College of Surgeons of Edinburgh, in another skeleton in the Royal College of Surgeons in London, and in a case upon which I myself made a *post-mortem* examination there were no gross evidences of pituitary tumour or inadequacy.

In *Progeria* there is still more reason to suspect the influence of hypopituitarism. It has been noticed that nearly all the characters of progeria are the antitheses of those which appear in acromegaly. This comparison has been insisted upon by Professor Keith, who, in the course of his study of a skeleton from a case of this disease, (6) showed that in almost every particular the changes were contrary to those of acromegaly. It is hardly possible to read his paper without being convinced that the one disease is opposed to the other. In only one point was the evidence at fault: the sella turcica showed no satisfactory indication of there having been any growth disorder or deficiency of the hypophysis.

SEXUAL GROUP.

It has been pointed out that in many cases of acromegaly some of the most conspicuous symptoms may possibly be due not so much to interference with the pituitary secretion as to the elimination of the sex influence, and this applies even more to Fröhlich's disease. The importance of this fact becomes evident when we remember that throughout the animal kingdom chronic or incapacitating disease is prone to be correlated with sterility. Just as there is a close association between the vigour of the body and the reproductive power so, generally speaking, any serious decline in the capacity of a vital organ tends in subsequent generations automatically to cease by the operation of sterility. They tend to produce not only individual but racial death. Thus alcoholism, plumbism, syphilis, all tend to sterilisation. Acute or chronic mental disease, amentia, dementia, obesity, diabetes, chlorosis, pernicious anæmia, leukæmia, achondroplasia and many other disorders are associated with aplasia or degeneration of the sex organs. In all probability, therefore, the sterility which is met with in Fröhlich's disease and in acromegaly is no more than the emphatic expression of a correlation commonly met with when the circumstances of the body are conspicuously abnormal. The importance of the reproductive apparatus in the ductless gland system can hardly be over-estimated. It seems to be the keystone of the arch and to be implicated in every disorder. Reasons have been given for doubting whether its influence is solely or even mainly exercised through the medium of a secretion.

SUPRARENAL SYSTEM.

The suprarenal system is another example of a double organ with attendant satellites. Though at present experimental evidence points unhesitatingly to the medulla as the dominant partner, the facts of pathology indicate quite as forcibly that it is the cortex which is of the first importance. Of all the diseases associated with these glands that of which we have most detailed and precise information is Addison's disease. The extreme muscular debility, the sensational bronzing of the skin, the low arterial tension and the progressive cachexia of this disease combine to form a syndrome of the most striking and vivid individuality. It seems clear that this combination of phenomena is due to grave suprarenal inadequacy. As a rule the inadequacy is tubercular in origin. But this is not the sole cause, for, according to Rolleston, there are cases in which the suprarenals have been in a state of defective growth or development, or have been almost destroyed by fibrous degeneration.

Turning now to the disorders which have been attributed to *overgrowth* of the suprarenals we meet with striking discrepancies. Diseases so produced have been described or collected by Bullock and Sequeira (7) and by Guthrie and d'Este Emery (8) in well-known papers. These disorders differ according to whether they occur in the male or in the female. In the female there is sexual and skeletal overgrowth with obesity; in the male skeletal and muscular overgrowth, sexual precocity, general hirsuties and obesity. These two types are termed the 'precociously obese' and the muscular or 'infantile Hercules' by Parkes Weber. Disease of this description seems to be in genuine contrast in certain cardinal respects with Addison's disease. At any rate the muscular overgrowth with corresponding strength, and the precocious virility are opposed to the muscular weakness, the cachexia, the emaciation, and the sterility of Addison's disease. And on examination of the body after death this contrast seems to be confirmed, for in most cases there is found to be a hypernephroma. Czerny, moreover, has reported the occurrence of five cases of hypoplasia of adrenal medulla with hydrocephalus. (9) Yet when we come to inquire a little further the evidence seems to be by no means convincing. Thus we read in one case that there was no normal suprarenal on either side, and the evidence of excessive action rested solely upon the presence of an abnormal collection of material of the size of a walnut close to the hylum of one kidney. This, it is true, was composed for the most part of tissue resembling that met with in adrenal cortex. But it was a tumour formation of the nondescript order we term hypernephroma, much of it being in a state of degeneration, some of it suspiciously like carcinoma. Now these are not the appearances which we associated with an exalted activity, but on the contrary with impairment of function. If appearances were deceptive and the tumour tissue was really functionally active we should have expected a collection of the size of a walnut to produce more effect than two normal suprarenal capsules. Are we to infer that there was congenital absence of the suprarenals with compensatory hypertrophy of an aberrant gland proceeding to an extreme and ending in functional hyperplasia? If so, we have to deal with a state of affairs which does not occur elsewhere. Moreover, if a small hypernephroma produces such an effect, why do we not have a similar or much greater somatic overgrowth with the huge hypernephromata which sometimes occur without obesity? Then again, exactly similar changes are found in association with tumours of the ovary, of the testes, of the thymus, of the pineal gland! Yet again, similar tumours may be found with genital aplasia, as in Marchand's case, or with emaciaton. Evidently we can go no farther until we have received further evidence; the discrepancies are too many and we receive but little help from experimental research. From the evidence which we now possess we are far more justified in attributing the tumours to the infantile gigantism than we are the gigantism to the tumours, for in all these cases which have been reported the most constant array of phenomena are the overgrowth of the fatty, muscular, bony, and sexual systems, the tumour formation being erratic in situation, variable in size, and even uncertain as to its existence. Indeed, in most cases adenomata or hypernephromata are only found accidentally at *post-mortem* examinations, having given rise to no symptom whatever.

Nothing can more clearly show the need for caution in dealing with this subject than the fact that absence of adrenal glands in the fœtus is sometimes associated with an encephaly. We are no more justified in assuming a causal relation between these two malformations than between a cleft palate and a spina bifida. Moreover, we meet not only with anomalies of other ductless glands in association with sex precocity, but local developmental disorders of the extremities either by excess or defect. Indeed, one of the cases which is often quoted in favour of the suprarenal origin of excessive somatic growth should in reality be regarded as evidence against it. This was Hutchison's case of hemi-hyperplasia, in which adrenal hyperplasia occurred on the same side as the somatic. It is almost inconceivable that a secretion poured into the blood-stream from one of a pair of organs should influence the growth of only one side of the body.

The conclusion to which we seem to be entitled is that the suprarenal cortex is, like many other organs, correlated with the sex glands and with the formation of fat, and that when there is abnormal growth of the reproductive apparatus there is apt to be an associated disturbance in the adrenal cortex, but we are not justified in assuming that the one malformation is the cause of the other.

Conclusions.

We now come to the question as to the causes of the defective or the excessive action of any ductless gland. For the answer we have to go to genetics. This branch of biology shows that as there is a normal size and a normal action so also it is as inevitable as light to darkness that size and function must occasionally become abnormal and fall into extremes. Hence every plant, every animal, every organ is liable to the extremes of growth or of development. Variations of this sort may be either spontaneous and hereditary so as to constitute mutations, or they may be the result of less emphatic changes and be fluctuations. These latter are in varying degrees influenced by environment. I need go no further into this subject, for it has been dealt with elsewhere. (10) The criticism which naturally follows is to question the utility of terming a disease a variation. The reply is that it carries us on one stage further, brings the disease into line with the facts of biology, and enables us more rationally to trace its origin, understand its purpose, and provide for its treatment than if we regard it as a mere *lusus naturæ*, appearing without rhyme or reason.

By studying these extremes we arrive at some sort of conclusion, however hazy, as to the normal action of the glands in question. We find that by virtue of their secretions or in some more cryptic manner they preside over certain correlations of the body. These correlations are by no means rigid, but are indeed exceedingly variable, and this variability is most apt to be shown when crcumstances are abnormal. The adjusting mechanism of development is not only flexible but is more or less reciprocal, so that a ductless gland both influences development and is itself influenced by the changes of general development.

In the harmony which is produced by the concerted action of the ductless glands we have reason to suppose that the leading part is played by the thyroid. This supplies a stimulus for the metabolism of the body as a whole. During infancy and childhood, when it is most important that the fires of metabolism should be controlled, the influence of the thyroid is checked by the thymus gland, by the lymphatic system in general and perhaps by the pineal gland. These also bring about that delay of sexual activity which is so essential to the proper maturation and stability of the somatic faculties. Probably the first to break through this cordon of conservative influences are the adrenal glands, which awaken the dormant sexual organs and hasten the growth of the muscular and skeletal systems. At about the same time the skeletal system is still further stimulated by secretions from the pituitary gland. This secretion hastens the development of every organ in the body, including the sex organs. These latter now ripen apace, and, assisted by the combined action of the ductless glands, sometimes animating, at others restraining, carry the development of the body in waves and tides to its flood.

USE AND ABUSE OF HYPNOTICS. (*a*)

By W. H. WILLCOX, M.D., F.R.C.P.Lond.,
Physician to Out-patients St. Mary's Hospital, London, W.

It will be well clearly to define what is meant by the term "hypnotic." In its broadest sense it means a remedy for inducing sleep, and no doubt general measures, for example those of hydrotherapy, electricity, etc., might be rightly regarded as hypnotic in action. For the purposes of this discussion, however, it will be necessary to restrict the term "hypnotic" to the following definition:—"A drug or combination of drugs which produces sleep resembling natural sleep."

In every case of supposed "insomnia" it will be well first to make quite sure that absence of sleep really exists. Not infrequently a patient imagines that he has had a sleepless night, whereas he may have slept for several hours.

When insomnia really exists it must be remembered that this condition is only a symptom, and its cause in every case must be very thoroughly and carefully investigated.

The immediate recourse to hypnotic drugs is greatly to be deprecated, since frequently harmful results follow this procedure. Not only is there danger of the development of a drug habit, but commonly the

---

(*a*) Abstract of paper read at the eighty-first annual meeting of the British Medical Association at Brighton, 1913.

patient develops a sad lack of self-reliance, and is apt to think that he cannot exist without these artificial aids to sleep.

It must also be remembered that sleep induced by drugs is not the same as natural sleep, and has not the same beneficial value.

The following classification indicates the common causes of insomnia and the use of hypnotics may be necessary in any of them.

1. *Pain,* and other conditions which act as sources of irritation and prevent sleep, *e.g.,* cold, heat, light, irritative bed-clothing, eye strain, adenoids, pruritus, etc., etc.

2. *Nervous Causes.*—(*a*) Psychical causes in the sane, *e.g.,* mental emotions, as grief, worry, shock, etc. Intellectual overwork, change in the mode of life, neurasthenia, hysteria, hypochondriasis, etc. (*b*) Cerebro-spinal causes, *e.g.,* cerebral irritation, meningitis, etc. (*c*) The insomnia of insanity.

3. *Toxic Causes, e.g.* (*a*) Microbic and parasitic infections, as pneumonia, typhoid fever, influenza, rheumatism, etc. (*b*) Chemical poisons, as alcohol, tea, coffee, lead, tobacco and the insomnia so characteristic of the drug habit. (*c*) Auto-intoxications, *e.g.,* gout, renal disease, fatigue, etc.

4. *Gastro-Intestinal Causes, e.g.,* dyspepsia, dilatation of the stomach, constipation, and the various diseases of the gastro-intestinal and alimentary organs.

5. *Cardio-vascular Causes,* such as arterio-sclerosis, angina pectoris, and diseases of the pericardium, myocardium or endocardium.

6. *Respiratory Diseases, e.g.,* asthma, bronchitis, pneumonia, etc.

7. *Genito-urinary Diseases.*

8. *The Insomnia of Physiological Epochs, e.g.,* menopause, old age.

It will be universally agreed that in every case of insomnia, after having carefully determined the ætiological factors, the first therapeutic measures should be directed towards the

Treatment and Removal of the Cause.

Any pathological condition present, should be treated by those special therapeutic measures most suitable for the particular case.

In addition, general measures for promoting sleep should be carefully considered and recommended, such as a modification of the mode of life and habits of the patient as regards work, rest, diet, exercise, smoking, etc. The conditions of the bedroom and bed itself as regards comfort, quiet, proper ventilation, warmth, etc., should be made suitable. The taking of a hot drink before bed time may be found to suffice. Simple measures of hydrotherapy such as baths, douches, and in severe cases warm or cold packs, may be employed before hypnotic drugs are given. In some cases massage, or electrical treatment have been found helpful.

The dangers and objections attaching to the use of hypnotics should always be carefully borne in mind. They may be summarised as follows:—

1. *The Unnecessary Use of Hypnotics.*—There should always be a real necessity for the employment and continued use of hypnotics for reasons given above.

2. *The Danger of the formation of a drug habit.*—This applies especially to certain hypnotics, such as morphine and opium preparations, veronal, chloral, paraldehyde, etc.

3. *The Danger of Toxic Symptoms resulting from the use of hypnotics.*—A single medicinal dose of a hypnotic drug may cause unpleasant and even alarming symptoms, and the continued use of these remedies may produce toxic symptoms, either by the simple effect of a repeated therapeutic action, or as in the case of drugs which are slowly absorbed, such as sulphonal, trional, etc., by a cumulative action.

The cumulative action of drugs which are slowly absorbed is often prevented by the avoidance of constipation.

4. *The Danger of Fatal Poisoning.*—Fatal poisoning is generally due to the patient gradually increasing the dose of the hypnotic, unknown to his medical adviser, so that ultimately a dose is taken which produces dangerous of even fatal symptoms.

5. *Special dangers due to existing disease, or age of the patient.*—In certain diseases there is a greatly increased susceptibility to particular hypnotics, *e.g.,* morphine and preparations of opium are especially potent in renal and respiratory disease and in cirrhosis of the liver; also in children these hypnotics must be prescribed in very small doses.

6. *Idiosyncrasy.*—Certain individuals have an increased susceptibility to some hypnotics, so that a large dose should not be given for the first time.

7. *The use of hypnotics when other measures of treatment should be employed.*—In many cases instead of giving hypnotics, the giving up of work and the adoption of some special treatment ought to be advised.

The Principal Hypnotics.

I. *Derivatives of Methane.*—These may be subdivided thus:—(*a*) *The Chloral, Alcohol Group, e.g.,* chloral, chloralamide, chloralose, butyl chloral, chloretone, hypnal, dormiol, isopral, viferral, ural, bromal, alcohol, paraldehyde, amylene hydrate, aponal, neuronal.

(*b*) *The Sulphonal Group.*—Sulphonal, trional, tetronal.

(*c*) *The Ureide Group.*—Urethane, hedonal, veronal and its derivatives, medinal (sodium veronal), proponal, luminal and sodium luminal, codeonal, adalin, bromural.

II. *Opium and its preparations and alkaloids and their derivatives.*—The various official preparations of opium, morphine, and its preparations:—Codeine, apomorphine, heroin, dionin, omnopon.

III. *The Atropine group of hypnotics.*—Atropine, hyoscine or scopolamine, hyoscyamine, the vegetable preparations of hyoscyamus, stramonium and belladonna.

IV. *Cannabis Indica and its preparations.*

V. *The inorganic bromides.*

VI. *Vegetable hypnotics other than those mentioned above,* such as hops, sumbul, etc.

VII. *Other hypnotics.*—Phenacetin, acetanilide (antifebrin), phenazone (antipyrin), pyramidon, aspirin, novaspirin, camphor monobromide, pellotine, etc.

Many of the abuses of hypnotics have been indicated in the above remarks. In addition, it is important to bear always in mind the dangers of "self-drugging" on the part of patients. Every patient taking hypnotic drugs should be impressed by his medical adviser with the undesirability of taking these except in real necessity. In giving prescriptions for hypnotic remedies the drug prescribed should be dispensed in such a way that the patient will not be induced to purchase the remedy for himself and dose himself. Bottles of tabloids of hypnotic drugs should never be supplied except with a written label according to the directions of the prescription (the printed trade label should not be on the bottle). It would be most desirable if definite hypnotic drugs were only supplied on the prescription of a medical man. In the case of drugs of a powerful hypnotic action it would be desirable if medical practitioners wrote on the prescription: "Not to be repeated."

Many of the abuses of hypnotics can be prevented by a loyal co-operation of pharmacists with the medical profession, and this co-operation will be to the great advantage of the public and all concerned.

INFECTIOUS ARTHRITIS. (a)

By EDWARD L. COOLEY, A.B., M.D.,
St. Louis, Mo., U.S.A.

Under the above caption may be classed all pathological joint processes which simulate, clinically or histologically, those diseases wherein bacteria or their toxins induce lesions elsewhere in the body. In joint inflammations the cause, for the most part, is traceable to some specific infectious agent. The more acute or abrupt the onset, the more readily can the nature of the cause be inferred. The resultant tissue changes are due either to the organisms them-

---

(*a*) Paper read at the International Congress of Medicine, London, 1913.

selves or to the presence of their toxins. Absolute demonstration of the infecting agents themselves *in situ* is extremely difficult, often impossible, as they may lie remote from the involved tissues, and the trouble be due to the presence and activity of their toxins. It has been contended that toxins do not cause joint inflammation; this contention being based upon the fact that toxin cultures injected into joints do not give rise to such pathological states. As opposed to this view, it can be urged (1) that oftentimes no infecting bacteria can be demonstrated at the site of the lesion or in the contiguous tissue, even in very acute cases. It is hardly presumable that such bacteria are so short lived, or that they are present in such small numbers as to escape detection.

(2) Anaerobic cultivation of the "smears" might not produce the same results as those obtained by aerobic methods. In the light of present knowledge we are not warranted in discarding the theory that probably the majority of chronic poly-articular inflammations are the result of toxins.

Ætiology.—In seeking the cause of these pathological processes all sources of infection, remote or recent, must be investigated. Infectious diseases, especially in the young; tonsillar inflammations particularly if recurrent; earache with or without suppurating sinuses through the tympana; evidences of syphilis; the presence of cardiac, particularly valvular, lesions; glandular enlargements with or without suppuration; intra-abdominal or intra-thoracic suppurative processes; all should be viewed with suspicion and investigated as possible causes. Chronic intestinal trouble, puerperal sepsis, long-standing low grade inflammation of the uterus and adnexa, inflammation of the deep urethra, prostate and seminal vesicles in the male, are competent factors in the causation, and pneumonia and la grippe are frequent causes of joint involvement.

All of the above factors have been held responsible for joint affections in some form or other.

Method of onset.—In determining the infectious nature of an arthritis the character of the onset is of great significance. It may be said in general that infectious processes begin abruptly and suddenly and quickly reach the climax. This is certainly true of the graver forms, *i.e.*, those following gonorrhœa. In some instances the onset may be slow. As a rule, the suddenness and gravity of the onset is more or less in direct proportion to the virulent infectivity of the organism; so that a failure to conform to the general rule does not militate against the infectious character of the arthritis. Another characteristic of this trouble is its poly-articular appearance from the onset. The first joints may be only mildly involved and of transient duration. The attack finally concentrating upon a few joints, possibly only one or two, which become permanently involved.

As a rule, the fewer joints involved, the more severe the attack. Another significant fact, though not infallible, is that the infectious process practically involves all the articulations liable to attack at the onset; herein differing from other forms of arthritis wherein the tendency is spread *ad seriatim* to other articulations.

Physical signs.—These vary with the severity of the infection, though in all persist the classical signs of an inflammation. In addition, there are limitation of motion, impairment of function, muscular spasm, and, later on, deformity. As secondary symptoms and evidences of toxæmia, general glandular enlargement, splenic and hepatic hypertrophy, cardiac complications, anæmia, slight but constant deviation of temperature, and an habitually high pulse-rate may be present, in all or in part. The chief subjective symptom is pain, which in severe cases becomes very annoying; interfering with sleep, causing loss of weight, and often a high degree of anæmia.

Pathology.—In the present state of our knowledge little or nothing can be hoped for looking toward an absolute differentiation of the various organisms and their toxins as cause and effect. Any attempt to associate pathologic appearances with any given variety of organisms or their toxins becomes infinitely difficult and the results uncertain. The following points, however, may be noted: (1) the appearance of the synovial side in the infected joints. Here the fibrous and synovial capsules, especially in severe affections, are adherent and difficult to differentiate, the cavity obliterated, and the interlocking adhesions so firm as to resist any separating force. Owing to the hyperæmia accompanying infective processes the vascularity is great and adhesions form more readily than in other forms or arthritis. (2) The sub-synovial part is usually entirely obliterated by infiltration of the tissues with round cells and the products of a low grade inflammation. This infiltration is much greater in infectious cases than in other forms of arthritis; consequently the combined thickness of the synovial membranes is usually greater than that seen in other forms. Upon opening the joint cavity much villous thickening may be present, differing in character from that seen in other forms of joint troubles. The more chronic the infection, the greater the liability to marked villous change. (3) An excess of fluid can, as a rule, be demonstrated in these joints, varying all the way from pus to a turbid exudate wherein flakes of inspissated fibrin may be present.

Bacteria.—It is very probable that attenuated members of the principal families of bacteria may and do produce the mild forms of infection, but of this we have no definite knowledge. In the case of streptococcic infection, it would be impossible to distinguish between the large numbers of varieties of this organism that might be present. The staphylococcus is never responsible for poly-articular infections and rarely for mon-articular ones save in direct infections from without, as part of a general pyæmic process, or due to the extension of a juxta-articular osteomyelitis. The gonococcus is a prolific source of infection; and the pneumococcus, bacillus coli communis, and others have likewise been traced as causes; but the majority of the chronic poly-articular infections are probably due to the so-called "Schuler's organism," not yet isolated; and until more accurate knowledge along this line is forthcoming all that can be definitely said is that some organism other than the well-known types is very likely responsible for chronic forms of joint infections.

Treatment.—Recognising an infectious element within the body as the cause of this form of joint disease, and that activity of the disease means a similar activity of the cause, the first step in the treatment is to locate the source of the infection and attempt its removal. If for any reason this source cannot be located, every effort should be made to increase the resistance of the patient and make the organism itself control the spread of the disease.

Hygiene, which is chiefly depended upon in dealing with tuberculosis, is of similar value in these cases; systemic resistance to one group of organisms infers a similar ability upon the part of the organism to resist the attacks of another, and what is efficient in one is relatively so in others. The same can be said relative to tonics and dietetics. In fact the general treatment of chronic joint affections of this type parallels very closely that of tuberculosis, *i.e.*, early recognition, absolute physical and mental rest, and life in the open air. In this form of arthritis, if ever, and then only in the more acute stages, is a restricted diet indicated.

In the sub-acute and chronic stages, ingestion of whatever food agrees with the patient is desirable, and in many cases forced feeding should be practised The cardinal points, therefore, in the general treatment of all sub-acute and chronic cases are: (1) Wholesome food: (2) Good hygiene; (3) Comparative freedom from pain. The use of drugs is incidental and employed only to meet the exigencies of the hours.

Local treatment—The demands in this field usually call for all our resource and skill. Here two cardinal points obtain. (1) Absolute immobility of the affected parts; (2) the earliest possible evacuation of pus and subsequent adequate drainage. The immobility must be absolute to be effective; no half-way measures will suffice. Fix both proximal and distal joints. If the knee-joint be the one involved, fix both hip and ankle-joint in a plaster cast, cutting out a window over the inflamed joint if necessary. So with any joint implicated. *Absolute fixation* lessens pain, diminishes swelling; limits peri-articular infiltration, and prevents deformity. It must not be forgotten that while rest is the initial step in the treatment, it is not always the foremost indication at the outset, and under certain conditions more radical measures must be adopted. Suppurative pyæmic joints which are frankly so from the onset will brook no delay. These must be treated on the broad principle of giving vent to the abscess within the joint cavity by as thorough methods as possible, sacrificing anything to that end. In some toxæmic joints where the trend is progressively bad, as indicated by constant high temperature, great sensitiveness, and excessive pain, the joint should be opened, thoroughly irrigated, existing adhesions broken up, the capsule closed, and a silk seton inserted for temporary drainage; then fix the limb in the most favourable position for function should ankylosis ensue. Where surgical interference of this character is necessary, it should be followed up as soon as possible by passive and active joint manipulation with early massage and hydrotherapy. These measures facilitate the early absorption of any infiltration of the capsule which may have rendered it stiff or inflexible, prevent formation of permanent adhesions, and break up those already formed. Some cases may require an arthrotomy in order to remove the products of inflammation, as inspissated fibrin; or to dissect out hypertrophied villi which may either contain the organisms responsible for the infection or mechanically curtail the free use of the joint. Complete regeneration of the synovial membrane usually takes place if only a little of the endothelial tissue is left; hence a very free dissection of the capsule can be made without risk of damaging adhesions resulting therefrom. When the object is simply the removal of villi, the lateral incision instead of severing the patellar tendon or going through that bone should be one of choice, on account of the greater likelihood of regaining motion.

Patellar section should be reserved for suppurative cases where free drainage cannot be secured by lateral incisions. In the after treatment determined effort should be made to overcome deformity and restore function. In a certain percentage of cases this can be accomplished by massage, electricity, and hydro-therapy. Others, again, will demand more radical measures, as the injection of sterilised oil, etc. The use of thick pads of fat or fibrous tissue dissected up from surrounding parts and turned into the articulations covering the crowded surfaces. This latter method is more applicable to the hip, shoulder, and elbow-joints, where a limited motion will suffice. In the knee and ankle, this procedure is not of much advantage because the amount of motion is too limited. Cargile membrane has been used where fat or fibrous tissue were not at hand, but this material was found too absorbent for the purpose. In those cases where the destructive processes have been great, and marked deformity has resulted, osteotomy and resection of the joint must be resorted to. Sometimes a tenotomy of contracted tendons, with the clearing out of the villi and old adhesions within the joint will suffice. Where the object is to correct deformity and restore function, ankylosis having already supervened, osteotomy is the operation of choice. Never disturb an old ankylosis if it is complete, if by any possibility it can be avoided and the deformity corrected.

In incomplete ankylosis a resection is indicated but recurrences are by no means infrequent. It requires two or three years to secure firm osseous union after a resection, while two or three months is the limit in osteotomy. Do not be in too great a hurry to remove the cast. The patient should wear a plaster cast at least one year after a resection and a walking splint for the same length of time thereafter to ensure permanent results. In carrying out the expectant plan, if after a lapse of two years bony ankylosis does not result it is useless to wait longer; a resection of the joint is indicated, provided always that the villi and other impedimentous tissue have been cleared away, for complete ankylosis will not take place so long as these products of the inflammatory processes remain.

ERGOT AND ITS PREPARATIONS. (*a*)

BY F. H. CARR, F.I.C.,

AND

H. H. DALE, M.A., M.D.

SINCE the last revision of the British Pharmacopœia in 1898, our knowledge of the chemistry and pharmacology of ergot has been advanced to so great an extent that it is now possible to devise processes for the official ergot preparations based upon the known properties of the active ingredients instead of adhering to the empirical methods

---

(*a*) Abstract of Paper read before the British Pharmaceutical Congress, July 23rd, 1913.

which were necessarily adopted at the time of the previous revision.

In a paper by Carr and Dale read before the British Pharmaceutical Conference on July 23rd, it was shown that the properties of the most important active substance in ergot, namely, the alkaloid ergotoxine, are such that the usual methods employed for making extracts of ergot tend to exclude rather than to include it; an explanation is thus given of the uncertainty with which these preparations are regarded by some members of the profession. The authors further recommend processes by which pharmacopœial preparations of high activity may be made.

The chief active principles of ergot are ergotoxine, *p*.-hydroxyphenylethylamine ("Tyramine") and *β*-aminazolylethylamine ("Ergamine"), all of which can now be obtained in pure crystalline condition.

The alkaloid ergotoxine is the essential active principle of ergot and is capable by itself of producing the true therapeutic effect of ergot. The amines, "Tyramine" and "Ergamine," have also an important stimulant action upon the muscular wall of the human uterus, and their presence in ergot extracts is a useful adjuvant to the action of the ergotoxine; to the latter, however, greatest importance is attached. Although the amines are readily extracted by water, and so are present in extracts and infusions, ergotoxine has properties exceptional in an alkaloid, whereby it is very apt to be left unextracted or to be precipitated from solutions. Its salts are very little soluble in water, though they may form colloidal solutions from which they are thrown down by strongly ionised acids or their salts. Ergotoxine is unstable in the presence of alkalis, while heating with strong alcohol converts it to inert ergotinine.

With a knowledge of these properties the reader will easily understand what the authors have actually found to be the case, namely, that as made under pharmacopœial directions both the Extractum Ergotæ (Ergotin) and Extractum Ergotæ Liq. possess but an insignificant proportion of the activity of the ergot, for in the former instance the alkaloid extracted initially by alcohol is precipitated firstly by the removal of the alcohol during evaporation, and, secondly, by the addition of hydrochloric acid; such addition would precipitate ergotoxine from pure solutions, but in this instance the process is facilitated by the absorbent action of the resins also thrown down; while in the latter instance the liquid extract, which is made with water, contains only a very small proportion of the sparingly soluble ergotoxine, the amount so dissolved being slightly greater in the case of a particularly acid ergot or if fermentative changes set in during the process. These extracts are rich in amines, and to such they chiefly owe what activity they possess, which, however, does not in any way represent the true clinical value of the drug.

On similar grounds the Infusum Ergotæ is criticised, while the instability of the ammoniated tincture is accounted for by the action of the added alkali.

The authors propose a revision of that section of the British Pharmacopœia relating to ergot, and indicate the following changes:—

1. The present Extractum Ergotæ to be abandoned and, if necessary, a soft total extract made with 60 per cent. alcohol acidified with citric acid, substituted for it.

2. The fluid extract of the United States Pharmacopœia, made with 49 per cent. alcohol, containing 2 per cent. of acetic acid, should take the place of Extractum Ergotæ Liq.

3. The Injectio Ergotæ to be abandoned and suitable salts of ergotoxine, either alone or combined with the active amines, Ergamine and Tyramine, to be employed in place of it.

4. The adoption of a liquid extract such as that described would render the tincture unnecessary, but such if retained should be made by percolation with 60 per cent. alcohol without ammonia.

Another point of interest noted is that it has been shown by testing ergots of other grasses, such as that of wheat and of a wild grass from New Zealand called Festuca arundinacea, that they possess even more activity than Ergot of Rye, Ergot of Festuca being found approximately three times as active as good Rye Ergot, and Ergot of Wheat slightly more active than the latter. The authors suggest that if an acceptable method of testing ergot can be found, such ergots should receive official sanction.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Carcinoma of the Breast.—Mr. Willmott Evans operated on a woman, æt. 64, who had been admitted for a swelling of the left breast. She had noticed the swelling for about a year, but she had not considered it of any importance as it gave her no pain. It had steadily increased in size, and ultimately she had had some twinges of pain in it, and then she came to the hospital.

On examination, the left breast was seen to be obviously enlarged, and a mass was felt in it involving mainly the upper and outer segment; the nipple was somewhat contracted; the skin was adherent over the tumour and dimpled, and when the pectoralis major was put on the stretch the tumour was found to be clearly adherent to the underlying muscle. The mass was hard and obviously situated in the substance of the gland. On examination of the axilla several enlarged glands were felt, situated mainly on the upper side and fairly firmly fixed. Nothing could be felt above the clavicle, and there was no evidence of the existence of any secondary growth. The patient's general health was good and there was no cachexia.

A diagnosis of carcinoma of the breast was made, and it was decided to operate. An incision was made, starting about an inch above the xiphoid cartilage, passing about three inches above the nipple, and reaching to the tip of the acromion process. A second incision was made, commencing at the same spot, and passing three inches below the nipple, and joining the first incision about an inch below the tip of the coracoid process. The skin was raised from the axilla, the tendon of the pectoralis major was cut through near its insertion, the pectoralis minor was divided, and the contents of the axilla were removed completely, the axillary vessels and the brachial plexus being fully exposed as far as the apex of the axilla, the first and second digitations of the serratus magnus being clearly seen. The mass thus removed was wrapped in gauze while the breast was dissected out; this was then taken out in one mass with the axillary contents, and with it were also removed the sternal portion of the pectoralis major and the tissues between it and the pectoralis minor. All bleeding was arrested, and then it was found that it was possible nearly to cover in the raw surface by suturing the skin. No drainage tube was employed; gauze dressing and cotton wool were applied and then a bandage, the arm being left free.

Mr. Evans said there were several points of importance in this case. As to the diagnosis there could be no doubt: the hardness of the mass, the retraction of the nipple, the adhesion of the mass to the skin and to the muscle, and enlargement of the glands left no room for difference of opinion. The question, however, arose as to whether the case was one suitable for operation. It was by no means an early case; all the signs Mr. Evans had enumerated showed that; besides, the involvement of the axillary glands was extensive. But, on the other hand, the supraclavicular glands showed no evidence of involvement, therefore he considered that it would be worth while to attempt removal, though the ultimate prognosis could not be called good. With regard to the incision, it was important, he said, to remove sufficient skin; in his opinion it was desirable not to let the incision enter the axilla at all, but to keep it well up on the shoulder. It was always desirable to remove part of the pectoralis major, but it was not necessary in the majority of cases to take away any of the pectoralis minor, though it was important to cut this muscle across, as this facilitated greatly the clearance of the axilla. He thought it important not to fix the arm in any way, but to allow it to assume any position the patient wished. In this way it was possible, he considered, to obtain greater mobility of the arm subsequently than by any other method.

The wound healed by first intention excepting for an area some inch and a half square where the flaps had not met; this area was subsequently covered with a skin graft. The patient left the hospital three weeks after operation.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, Aug. 30th, 1913.

At the Laryngological Society, Hr. Hölscher showed a case of

TOTAL EXTIRPATION OF LARYNX AND PHARYNX.

The operation had been performed a year ago. There was nothing specially of interest in the operation itself, but later, in the carrying out of plastic procedures, there were difficulties chiefly in that in consequence of the skin incision the nourishment of the flaps required in the plastique of the pharynx was unfavourably influenced. It was understood that in cases of extirpation of the larynx and pharynx the skin flaps were again united and fixed by tampons against the vertebral column. As the nutrition of these flaps appeared to the speaker to be endangered, he had, as a rule, made two. The flaps were here separated, turned round, and sutured to each other, so that the epidermis lay inwards. It required no explanation, therefore, that the nutrition of these flaps was influenced unfavourably. As a matter of fact, necroses of them sometimes took place. In the case before them, such a necrosis took place just above the tracheal opening. Here an opening was formed. After recovery had taken place so far, another operation was performed, in which complete closure, as intended, did not occur. Necrosis of a small portion again followed, which, however, contracted so much that by Christmas it was only threadlike. Another operation was then performed by a colleague, but no success followed, the opening, in fact, became larger—9 to 10 mm. in diameter. For the patient it was, of course, the reverse of agreeable; from August to the following April she had to feed herself through a nasal sound. She objected at the time the speaker saw her again to immediate further operation, but she wished to get free of the sound feeding. He first tried to block up the opening by a rubber knob. A flattened knob was made of soft rubber, and this was so firmly held against the edges of the wound that it formed an almost watertight closure. The patient could now eat and drink, but the arrangement could not, of course, be a permanent one. He hoped shortly to try another plastic operation, which might be more successful.

Then the patient experienced a misadventure. She fed herself through the sound, but one day in October of last year, she had forgotten to replace the clamp after taking food. The result was that, making an involuntary swallowing movement, she swallowed the sound, which was as thick as the little finger. The speaker heard nothing of the accident until a week later. The X-rays showed the sound lying along the greater curvature of the stomach. The tip had passed above the pylorus, so that it could not enter the duodenum. The tube was still in the stomach and was causing no trouble, as the patient was looking hearty and well.

She also gave him another little fright. In April a tumour appeared below the angle of the jaw on each side. He thought it was a recurrence, but later on he was satisfied that it was only that the salivary glands had become pushed down a little lower. As a precaution, however, he took a portion from one of the tumours, and sent it to the Pathological Institute for examination, where it was declared to be nothing but normal glandular tissue.

Hr. Blumenthal said that he had had a similar experience; he had sutured in the mid-line, hence the necrosis. The sutures should not be placed directly over the new œsophagus, but arranged so that the line of suture should fall on the side. Here the suture cicatrix would be better nourished than from the central line.

Gluck formed a flap from the side, a much wider one than that of Hr. Hölscher. If any tension took place, as when the line of suture lay directly over the new œsophagus, the wound must get thin and break through.

At the Aerztlicher Verein Frankfort, Hr. Raeske introduced the

SALVARSAN TREATMENT OF PROGRESSIVE PARALYSIS.

The view, he said, that progressive paralysis was a late form of syphilis and not a parasyphilitic affection, had been happily confirmed by the discovery of spirochætes by Noguchis. After this discovery it was natural that clinicians should approach the treatment of the disease with renewed hopes, and put into use the modern energetic forms of treatment. In the case of 65 paralytics, the speaker had carried out the treatment by salvarsan. In a larger number of the cases he had achieved a success that represented more than the remissions that were occasionally observed. The improvements showed themselves mostly somatically in increase in weight from 20 to 30 lbs. Ataxy, stuttering, test writing showed distinct improvement. On the other hand, the weakness of judgment was in no way improved. In like manner lost reactions such as the pupillary and patellar reflexes were never restored. The improvement did not extend over a long period. During treatment very considerable improvement was obtained in five cases, 31 showed distinct improvement, 26 remained unchanged. In two cases the disease got worse, and one died. The last three cases showed idiosyncrasy as regarded salvarsan. Salvarsan was given up to 8 grm. pro patient. After from two to three grm. had been given in a case a pause was made.

The speaker concluded that his experiences encouraged to further trials of the method of treatment.

HUNGARY.

Budapest, Aug. 30th, 1913.

GONORRHŒAL PHLEBITIS.

A case of this rare complication of gonorrhœa is reported by Dr. Veress Tozsef (*Orvosok Lapja*, August 7th, 1913), in a young man who developed a marked phlebitis in the lesser saphenous veins about four weeks after an attack of acute gonorrhœa had apparently subsided. This gradually disappeared with the use of evaporating lotions. From a study of fourteen cases thus far reported, it seems that the affection is usually present in young men during the subacute stage of a first attack of urethritis. In most of the cases an arthritis was also present. Varicose veins were seen in only one instance, so that this condition cannot be looked upon as a predisposing factor. The saphenous vein seems to be most often involved. Pain and œdema are the main symptoms, and six weeks the usual duration of the affection. Dr. Veiess believes that the affection is due to the rupture of some hitherto unrecognised focus, probably in the prostate, from which the septic material enters the venous system. The treatment is the same as that of phlebitis in other parts.

Ætiology of Prolapsus Uteri.

An interesting theory as to the causation of this condition is advanced by Dr. D. Burger (*Gynæcologia*, July, 1913). He cites the case observed by a German gynæcologist who found in a newborn child that there was complete prolapse of the vagina and uterus, degeneration and atrophy of certain groups of muscles in the lower extermities, atrophy of the pelvic floor musculature, as well as sensory paralysis of the lower limbs and the trunk as far as the upper border of the spina bifida. The author has had a similar case short of the atrophy of muscles and paralysis. He believes these cases will explain the cases of uterine prolapse occurring in women who have never borne children (about 3.5 per cent. of the cases according to Burger). In these instances the factors usually brought forward are insufficient, such as manner of living, occupation, venereal excesses, improper nourishment, inflammations and tumours. Freund attributes the condition to infantilism, others to an insufficient development of the peritoneum. In searching the literature, the author has found fourteen cases where this dislocation of the organs was already noted in the new-born child; ten of these also presented a spina bifida. He therefore set aside the supposed influence of an infantile condition or the constitution of the peritoneum, and concludes that the association of spina bifida, atrophy of the pelvic floor muscles, and genital prolapse, can be attributed to some disturbance of the sacral nerves, which results in the production of the anomalies in question. This view seems to be confirmed by instances seen in older individuals, where some injury affecting the sacral plexus is followed by not only a primary nervous disturbance, but also a secondary uterine prolapse.

On Syphilitic Aortitis.

Dr. J. Tanosi has often observed inflammatory changes in the aorta, which manifest themselves as small infiltrations around the vasa vasorum of the adventitia. This infiltration may extend to the media and may become so intense that portions of the media are destroyed completely. The ætiology of this process is very frequently syphilis, but it must not be forgotten that alcoholism and certain infectious diseases may be responsible for exactly the same lesions. Hence syphilis can never be diagnosed absolutely from the condition of the vessels, but if the granulation tissue of the media changes into connective tissue, which has a tendency to form a deep, retracting scar, which manifests itself microscopically as a puckered depression, the case is very suspicious. Even extensive inflammatory changes alone in adventitia and media will not enable a diagnosis.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

DR. EWART ON THE APEX TREATMENT FOR PULMONARY CONSUMPTION.

To the Editor of The Medical Press and Circular.

Sir,—I have read Dr. William Ewart's papers on apex treatment of pulmonary consumption that have been appearing the last few weeks in your columns with much interest, and can endorse all he says respecting the neglect of the mechanical factor in drainage of the lung when cavities invade the pulmonary tissue.

I still find that the inclined prone couch which I devised some years ago, and to which Dr. Ewart refers in his concluding article in your last issue, assists greatly in evacuating the foul secretions of chronic cases, and answers the expectations I formed of its utility. Perhaps it may be tried on a larger scale by those practitioners who are now relinquishing the treatment by tuberculin!

I am, Sir, yours truly,
Tucker Wise.

Dartmouth, Devon.
August 21st, 1913.

P.S.—Dr. Ewart mentions my name as of Montreux. I may be allowed to say that I have ceased practice there, the winter climate and the hotel accommodation not proving particularly suitable for tuberculosis.

"CROWNER'S 'QUEST" AND MEDICAL LAW.

To the Editor of The Medical Press and Circular.

Sir—It is to be hoped that the report of an inquest at Croydon, on August 26th, and published in the *Times* of the following day, will not escape the notice of the General Medical Council, and of those members of the profession who are working for medical law reform. It was proved in evidence that an unqualified and unregistered man had been practising as a medical man, and describing himself as "Dr.," for two years; that he had undertaken the treatment of a child stated to be suffering from "sickness and diarrhœa," and that the child died before the arrival of a registered practitioner, who was at last sent for. The Coroner, Dr. T. Jackson, himself, apparently, a medical man, seems to have allowed the jury to return a verdict of "Death from natural causes," without calling for a *post-mortem* examination. Any inquest in which no attempt is made to determine the cause of death is a farce. I refrain from characterising this particular inquiry and from referring to the amazing statements made by the unqualified man respecting his relations with the registered practitioner called to the case. The bald facts given are perhaps enough for the professional reader, but you may care to print the fuller report from the *Times*, which I enclose.

I am, Sir, yours truly,
H. S.

August 27th, 1913.

[We refer to the case noted by our correspondent in our editorial columns.—Ed. M.P. and C.]

IS OPERATION USELESS IN CANCER OF THE WOMB?

To the Editor of The Medical Press and Circular.

Sir,—Ought one to order an operation for a patient who has cancer of the uterus?

The whole faculty of medicine seems to thunder "Yes—at least in suitable cases" in our ears; but let us calmly examine results and see could we justify the counsel, say in a witness-box, if a clever K.C. charged us with giving unsound advice?

Many of us went to the International Congress of Medicine hoping for light on this and other subjects. In the Section of Obstetrics and Gynæcology, Professor Wertheim, of Vienna—probably the first authority in the world—mentioned his conclusions in the matter.

There came before him, it appears, 1,428 cases of cancer of the uterus. Of these, the "operability rate" was 50 per cent. 714 cases were then operated on, and five years after 186 were free from recurrence.

Do these figures justify a common, ordinary practitioner in recommending operation?

I think not. About one patient in eight is found free from the disease after five years. If these 1,428 cases were left to nature, how many would be alive after five years? Possibly not one, but probably, I submit, at least 186, for the possibility of mistaking for cancer some non-malignant form of uterine trouble is much greater than one in eight. In fact, we are taught that it is criminal to wait until the diagnosis is absolutely established—the man who insists on absolute proof of the disease is considered to jeopardise his patient's chance of life.

Most medical men hate mathematics. They ignore that celebrated canon of Rodicke of Bonn: "That in order to prove the effect of a form of treatment, the difference between treated and untreated cases must be greater than the double of the largest possible error of observation—*i.e.*, greater than the sum of the uncertainties."

I submit that the survival of one case out of eight proves less than nothing when the chances that all the original cases were not true cancer are distinctly greater than one to eight.

I am, Sir, yours truly,
J. C. McWalter, M.D., F.R.F.P. and S.
Dublin, August 26th, 1913.

THE PROFESSION AND TRADES UNIONISM.

To the Editor of The Medical Press and Circular.

Sir,—As an advocate for many years of trades unionism in the profession, I have read with peculiar interest the leader on this subject in your last issue. It is, I think, a misfortune not less for the public than the profession that the question seems for the time to be outside the range of practical politics. This result has been brought about, of course, mainly through the vote at the last annual meeting of the British Medical Association. To form a medical trades union outside that body is virtually impossible, or, at any rate, only a minority of practitioners could be found to support it. The unfortunate situation is undoubtedly to a large extent due to the odium in which the denomination trades union is held. But trades unionism is not necessarily opprobrious. It is opprobrious only when entirely egoistic in character; when it subordinates every consideration to selfish ends, disregarding entirely the advantage of the community and the welfare of the State. No medical trades union can descend to such a level so long as medical men as a mass are imbued with a modicum of true professional spirit. The profession might strengthen its organisation and increase its power by adoption of what is best in trades union methods; but it must remain in spirit always a professional union, and not a trades union in any sordid sense of the word. If we had been so organised at the time of the introduction of the Insurance Bill, we should have had command of the situation. If we were organised as thoroughly for defence as are the lawyers in their trades union, we should be able to force forward the case for medical law reform which your paper has done so much to advocate—reform so much more called for in protection of the public than of the practitioner. It is to the interest of the public and the State that medical practitioners should be truly professional men of the highest possible attainments, gentlemen of wide general education and steeped in practical knowledge of their calling. This ideal cannot be reached without adequate recognition and protection of the profession by the State; and the claim for these privileges cannot be established and advanced without great delay unless the profession be solidly organised on trades union lines. Such an organisation would further rather than hinder the promotion of scientific work, upon its devotion to which the fame of the professon must ultimately always depend.

I am, Sir, yours truly,
A Member B.M.A.
Birmingham, August 29.

A DOCTOR'S WIFE ON DRESS.

To the Editor of The Medical Press and Circular.

Sir,—Your correspondent "Gynæcologist" evidently does not know everything about women that might be useful to him and advantageous to his clients. He does not evidently appreciate the fact that the happiness of women—and happiness connotes health, as health connotes happiness—is very largely involved in the æsthetic and scientific problem of dress. Women's dress forms a capital theme for jest, but it cannot be fairly or profitably treated entirely as a joke. From the æsthetic point of view I agree with the doctor's wife who opened this correspondence. The most pressing need for our countrywomen in this connection is emancipation from the French fashionmonger. British women are the most beautiful in the world. Nowhere else can you find so large a proportion of fine figures and faces; nowhere can you find so large an average of women whose persons when unadorned are really adorned the most. This is demonstrated among the considerable proportion who now stick to the simple fundamental principles suggested in the letter of "Doctor's Wife No. 3" in your last issue. To display their beauty is a natural and entirely laudable instinct in women, and one that cannot be suppressed as a rule without injury; and as there exists no more beautiful thing in nature than the human form divine, when such beauty is chastely displayed it promotes true civilisation, and enhances the happiness of mankind. The contours and the graces of the female form can be displayed without the lewd suggestiveness that mars so much of the Parisian modes of the day, and it is within the power of British women to keep clear of such extravagancies. The present extravagancies, as some of your correspondents point out, prevent the wearing of undergarments necessary for the preservation of health in our climates; and I can testify that a very great deal of illness among women is nowadays either directly caused or seriously aggravated by the blind pursuit of fashion which engages so vast a number of women of a certain standard of intellect.

I am, Sir, yours truly,
A Lady Doctor.
London, W.,
August 21st, 1913.

OBITUARY.

DR. T. ANDERSON, YORK.

We regret to record the death from enteric fever of Dr. Tempest Anderson, M.D., D.Sc., F.R.G.S., J.P., of Stonegate, York, which took place on his voyage home from the Philippine Islands. By his decease York loses a distinguished citizen, who by his original research in one of the byways of science had achieved a world-wide reputation in scientific circles. Born at York in the year 1846, he was a member of an old York family, being the eldest son of the late Dr. William Anderson, who filled the office of Sheriff in 1854. He was educated at St. Peter's School, York, and subsequently passed to University College, London, where he had a successful career, and gave promise of the distinction in the realms of science to which he afterwards attained. After studying abroad, he joined his father in partnership on his return to York, and subsequently succeeded to the practice, specialising in ophthalmic work, but he retained his general practice till his retirement about the year 1905. He was a considerable contributor on ophthalmic topics to the medical journals, and was the author of several papers read to the British Association, and furnished to the proceedings of the Royal Society on cognate topics. During the time he was in practice Dr. Anderson held several public appointments, including those of Ophthalmic Surgeon to the York County Hospital, Medical Officer to York Castle prison, and Surgeon to the North-Eastern and Great Northern Railway Companies. He also figured prominently and held office in the York Medical Society, of which he was an ex-president, and the West Riding Medical Chirurgical Society. In scientific quarters, and by the public generally, Dr. Tempest Anderson was best known as one of the most successful amateur photographers of the day, and as a leading authority on seismographic phenomena and volcanoes. His interest in photography dated from his boyhood, but owing to the engrossing character of his medical studies he early abandoned it; resuming it, however, in the early "eighties," through the suggestion of Mr. J. J. Harris Teale, afterwards Director-

General of the Geological Survey. He was, in later years, a frequent contributor to the exhibitions of the Alpine Club, and at the *conversaziones* of various scientific societies, and also, in late years, by special invitation, in the salon of the Royal Photographic Society.

It was in the domain of volcanic geology that Dr. Anderson shone, for his systematic researches into volcanic phenomena led to his official recognition as an expert, for in 1902, when, after the eruption of the Soufrière in St. Vincent and Mont Pelée in Martinique, in May, he was appointed with Dr. J. S. Flett, another Fellow of the Geological Society, to visit the Windward Islands and prepare a report on the subject on behalf of the Royal Society. Two years later he published his principal work, "Volcanic Studies." He was widely known as a lecturer, and one year was selected as Tyndall Lecturer on Volcanoes at the Royal Institution. In descending one of the foothills of Etna in 1908 Dr. Anderson strained his thigh. He was operated on, but the accident left him slightly lame for the rest of his life. A man of genial temper, he had a large circle of friends, and though a bachelor he entertained largely at his interesting old house in one of the recesses of Stonegate, in the heart of the city, among his guests being many interesting personalities in the scientific and mountaineering world. York people were naturally proud of their distinguished citizen, and the pride was reciprocal. Dr. Anderson recalled with satisfaction that he was a freeman of the city. He did his best to conserve the city's glorious heritage of antiquarian treasures, intervening with decided effect at more than one crisis to save objects of historic interest from the vandalistic designs of civic "reformers."

REVIEWS OF BOOKS.

PLANT RESEARCHES. (*a*)

This extremely interesting volume of scientific record deals, of course, with a department of biological investigation which possesses but little significance at present for the great majority of even metropolitan consultants; and none—we might almost say less than none!—for the average panel practitioner. But we have no hesitation in announcing our belief that, in the not very distant future, this department of investigation will be found to yield copious results, and throw search-light beams into many of the still unexplored dark corners of the tantalising borderland of physics and physiology of animal and vegetable life. And it is along those planes of contact that we feel most confidence in anticipating revelations of epoch-making importance in the prevention of disease and the prolongation of life.

The author has already contributed to the extension of our knowledge of vegetable physiology a substantial volume on "Plant Response." He here laments the fact, or feature, of "the very inconvenient and tedious process of photography," which he was obliged to utilise in establishing the results of his response recorder, which was a "modification of the optical lever." His perseverance was ultimately rewarded in the overcoming of all obstacles by the device of the resonant and oscillating recorders. The somewhat creepingly human Mimosa has inevitably come in for the lion's share of attention, and every inquiring biologist will learn with interest that, although it has "been held that there was no transmission of true excitation in Mimosa, the propagated impulse being regarded as merely hydro-mechanical, the present author has been able to establish the fact that "The sensativeness of Mimosa to electrical stimulus is high, and may even exceed that of a human subject."

HUMAN PHYSIOLOGY. (*b*)

The second volume of this treatise deals with internal secretions, digestion, excretion, and the skin. The book is delightfully written. The historical aspects of physiological progress receive special attention, and at the end of each section there is a good bibliography, which has been considerably augmented by the English editor, Dr. Camis. If the book has a fault it is that there is not quite that touch of dogmatism which one rather welcomes in a text-book, and the modern aspect of certain subjects is not clearly crystallised. As an example of the latter we may take the section on the pituitary. We are simply told that certain authors find that extracts raise the blood-pressure, certain others deny it. It is surely now common knowledge that pituitary extracts do raise blood-pressure, although inert specimens are met with. Then there is no mention of the diuretic or galactogogue action of the gland. Surgeons, at the present time, will be interested in the results of experiments quoted on page 521, in which the remarkable powers of iodine in penetrating the skin are shown. The translator's part has been well done, although we question whether the word "elegant" is the best to apply to an experiment on micturition, and we are mildly shocked by "ureterorrhaphy" (362), particularly when it is used to signify closure of the urethra.

TUMOURS. (*a*)

The contemplation of the special domain of tumours conveys with it, from our present view-point, the chastening—and, let us hope, cathartic—influence of that modicum of humiliation which we have evermore been assured is so essential to the maintenance of a duly hygienic condition of the human spirit. We have every sympathy with Dr. White in the position he has assumed at the origin of his thesis: of specially stressing the physiological aspects of his subject, and asking the questions *how* (?) and *why* (?) as well as *what* (?) He has evidently been inspired by genuine truth-seeking zeal in this pursuit—and it surely is a subject, or congeries of subjects, which requires the vigorous attentions of a battalion of enthusiastic explorers in order to the completion of its cartography and physical polity. Having to examine the foundations of a new structure, our author has started at the very beginning—the only proceeding, we feel bound to add, which could secure anything of confidence in his mode of procedure and statement of results. The text is divided into thirteen chapters, of which the first deals with "Variations in Development, Growth, and Functional Activity." This title by itself implies a connotation of the author's view-point and his aim, as well as method, of investigation. Accordingly, his procedure aims, at least, at a degree of thoroughness which cannot fail to enlist the discriminating reader's sympathy, and leads to arrangement of details and enunciation of opinions which the reviewer cannot attempt to deal with in a series within the limits at his disposal. We may, however, take the opportunity of stating that the best part of Dr. White's work is the close association of physiological and pathological histology, by the combined aid of which he has so earnestly endeavoured to trace the ramifications and tendrils of the root questions associated with our very much desiderated knowledge of the "Causation of Tumours," which forms the subject of the author's twelfth chapter. We cannot dare say that he has quite reached, far less plucked out, the heart of the mystery of tumours; but this volume indicates present high-water level.

DIABETES. (*b*)

As might be expected from a physiologist, the writer, instead of distributing his attentions over the whole of the vast domain of the clinical complex known as diabetes, concentrates his powers on "those investigations that have a more or less direct bearing

---

(*b*) "Human Physiology." By Professor Luigi Luciani. Translated by Francis A. Welby. In Four volumes. Pp. 558. London: Macmillan and Co. 1913. Price 18s.

(*a*) "The Pathology and Growth of Tumours." By Charles Powell White, M.D., F.R.C.S., Director, Pilkington Research Fund; Pathologist Christie Hospital, Manchester. Illustrated. London: Constable and Co., Ltd. 1913.

(*b*) "Diabetes: Its Pathological Physiology." By John J. R. Macleod, M.B., Ch.B., D.P.H., Professor of Physiology, Western Reserve University, Cleveland, U.S.A. London: Edward Arnold. 1913.

on the nature of the abnormal condition or conditions in the animal body that are the cause of the disease." There are very few pathological conditions known to us in which the clinical physiologist can display the value of his special attainments to greater advantage than in the examination of a case of diabetes, and conveying counsel regarding the treatment of its subsequent course, as well as in investigation of all available evidence regarding the original cause or groups of causes. Ever since the popularisation of Claude Bernard's epoch-making discovery of the glycogenic function of the liver, and the subsequent revelations of the complicated influences of the nervous system on the same, the subject has been one of curious symptomatic and therapeutic interest to the physician, and of correspondingly instructive experimental interest to the physiologist. And the gratifying conclusion is here enunciated by Dr. Macleod: "The physicians who have had most success with such cases are those who, by close attention to the results of experimental investigation, have a thorough knowledge of the physiological processes that become upset in the disease." But there still remains ample material for the exercise of clinical observation and experimental ingenuity; and fairly dense is the mist which still hangs over the borderland of diabetes. Even the "hormone" hypothesis, from which so much was expected at the time of its enunciation, has sadly failed to furnish forth the clinico-pathological explanation of the serial linkage of the phenomena of "pancreatic" diabetes, as it was for a time fondly hoped that it would inevitably be able to do. Dr. Macleod's welcome monograph clearly defines the line of demarcation between known and unknown, and for this we cordially thank him.

DISEASE IN CHILDREN. (a)

The opening chapter in this book on the feeding of infants and children in health is extremely good, and it is satisfactory to note that the author makes a vigorous protest against the "pap" method of feeding, and pleads for dietetics on more scientific lines. In Chapter II., two diseases related to diet—namely, scurvy and rickets, receive consideration. The author next deals with general diseases of infective origin, and in this connection we are glad to see he gives effect to the modern conception of the ætiology of chorea by including it among the rheumatic infections. After a chapter on the acute specific fevers which constitutes a new section in this edition, he discusses the diseases of the various systems. The concluding chapter on diseases of the integumentary system is also included for the first time in this edition.

For the book as a whole we have nothing but praise, and we can without hesitation recommend it as being suited to the requirements of the young practitioner.

NEW PREPARATIONS.

CITODA"—A SPECIAL SODA WATER.

We have received from Messrs. Jewsbury and Brown, Manchester, a special soda water, known as "Citoda," which is prepared with pure sodium citrate in the proportion of five grains to the half-pint, together with an equal quantity of sodium bicarbonate. The well-known property of sodium citrate in producing a very fine flocculent curd with the casein of milk in the stomach, renders it a most useful agent in the treatment of children and others who have to rely upon a milk diet. The water is pleasant to the taste, and it may be regarded, not as an ordinary mineral water, but rather as a valuable adjunct in the treatment of certain classes of medical cases in which it is desirable to maintain the alkalinity of the blood. "Citoda" is put up in syphons and retails at 6s. per dozen.

ORIENTAL TOOTH POWDER.

From the same firm comes a specimen of their Oriental Tooth Powder contained in a new hygienic "sprinkler" tin, which enables a whole family to use the same tin without any fear of contamination of the dentifrice, and, further, it is possible to use the powder up to the last grain. We have found this preparation pleasant to use. It is sufficiently alkaline and is flavoured delicately, while it cantains a sufficient amount of antiseptic to destroy the organisms of fermentation present in the mouth.

MEDICAL NEWS IN BRIEF.

Unqualified Medical Practice.

The Croydon Coroner (Dr. T. Jackson) held an inquest last week on the body of Harry Stephen Eldridge, aged eight months, of Beulah Road, West Croydon.

Harold Eldridge, the father, a grocer's assistant, said the child had sickness and diarrhœa, and he took him to "Dr." Sparling, of Northcote Road. There was a brass plate outside, "Dr. H. F. Sparling," a red lamp, and on the window was painted the hours of attendance. The witness received advice for the child and a prescription, to be made up at a chemist's, was written out. The witness received a bottle of medicine for himself, in continuation of treatment "Dr." Sparling was already giving him, and he paid 2s., believing he was paying it to a properly qualified medical man. Next morning, finding the child apparently dead, the witness went for "Dr." Sparling, who declined to come, saying he had a train to catch. He referred the witness to Dr. Morrison Orr, who attended and said that the child was dead.

Horatio Frank Sparling said he was an optician, and not a registered medical practitioner. He treated Eldridge and the baby as described, and produced the prescription.

The Coroner said it was quite a harmless one, which no medical practitioner would regard as improper for such a case.

The witness said that since the date of the baby's death the inscription on the brass plate had been altered to "H. F. Sparling." The word "surgery" was on the lamp, but over the hours of attendance there was a representation of a pair of spectacles. All "this paraphernalia" was due to the fact that a fully qualified medical man had been in practice there, who was, in fact, in partnership with the witness, though there was no written agreement. He admitted, after some hesitation, that his former partner was Dr. Morrison Orr.

The Coroner pointed out that the witness had committed a breach of the law by calling himself a doctor.

The witness replied that he had been under the impression that anybody could do that if he did not describe himself as a physician or surgeon. For two years he had been doing ophthalmic work only.

Dr. James Morrison Orr, registered medical practitioner, deposed to being called and finding the child dead from convulsions. He told the father to go to the Coroner's Officer and report the case. The witness's former partnership with Mr. Sparling was more a matter of friendship than actual partnership. The witness had the use of his surgery for his practice. Mr. Sparling was to dispense there, under supervision, and act as surgery attendant, which arrangement was with a view to his making an effort to get a qualification.

The Coroner reminded the witness that the General Medical Council had struck meny medical men from the register for having unqualified assistants.

The witness said he had had no personal or immediate connection with Mr. Sparling since he took up the optical business two years ago.

The jury returned a verdict of "Death from natural causes," expressing no further opinion.

The Coroner, addressing the last two witnesses, said that they had both sailed very near the wind. He hoped Mr. Sparling would take warning, and not carry on what was really a deception on the public.

(a) "The Treatment of Disease in Children." By G. A. Sutherland, M.D., F.R.C.P., Physician to Paddington Green Children's Hospital, etc. London: Henry Frowde and Hodder and Stoughton. 1913.

A False Insurance Claim.

At Brighton last week, William Sullivan was summoned by the Brighton and Sussex Mutual Provident Approved Society for having knowingly made a false declaration for the purpose of obtaining a sum of 10s.

Mr. Cushman, for the Society, said that since the Insurance Act came into operation there had been a great deal of malingering, and he asked that the case might be dealt with in a manner which would prevent other cases occurring.

Mr. Munday, secretary of the Society, said that the defendant declared himself "on the funds" on January 8th, having broken a leg while playing football. He became entitled to 10s. a week for six months, and during the 26 weeks four certificates were signed purporting to represent his incapacity. In June the defendant was fined 1s. for being absent from home after the hour at night set down in the rules. On July 11th the defendant's wife took to the office a declaration form signed "W. Sullivan" for continued sick benefit. He paid her 10s. On July 18th she presented another declaration signed by the defendant, but the witness declined to pay any money.

John West, road surveyor, gave evidence that the defendant worked regularly under him at Handcross from July 7th until July 16th, and from July 21st to August 1st. He worked from six to fourteen hours a day, including eight hours on July 11th. He would have to walk to the station.

Dr. Basil Jackson said he gave the defendant certificates on July 4th, 11th, and 18th, but he could not say that he saw the defendant each time.

One of the magistrates pointed out that they had direct evidence that the defendant was at work when two of the certificates were signed.

Dr. Jackson: A panel doctor has no chance when a patient is a hospital patient of doing more than I did. A patient may come to the doctor and say the hospital doctor has ordered him to lay up for a week, or twenty, and you cannot examine him because he is another doctor's patient. If you do not sign the certificate the poor, wretched patient does not get his money. What is a panel doctor to do?

The presiding magistrate, in sentencing the defendant to six weeks' imprisonment with hard labour, said: "The magistrates regret that such laxity should have occurred. We feel that this contributed to the offence, and we hope that greater care will be exercised in the future."

Re-opening of London Hospitals' Out-Patients' Departments.

After the annual cleaning and repairs, the outpatients' departments of the Royal Free Hospital, Gray's Inn Road, the New Hospital for Women, Euston Road, the Marylebone General Dispensary, and the Hospital for Diseases of the Skin, Stamford Street, were re-opened on Monday last.

Irish Medical Committee.

A meeting of the Irish Medical Committee was held in the Royal College of Surgeons, Dublin, on August 27th, at 2.30 p.m., Dr. MacNamara, of Kilmaleach, in the Chair. The following attended:—Drs. Marlay Blake, J. C. King, J. F. Fagan, B. C. Powell, J. Power, Stanley B. Coates, P. McKenna, J. S. Darling, R. W. Leslie, D. Gray, H. S. Morrison, P. J. Hamilton, T. F. Higgins, T. A. Davidson, R. J. Johnstone, E. W. Allsom, J. J. Waters, F. Fitzgerald, P. J. O'Brien, J. Ryan, J. F. Devane, R. P. McDonnell, J. Keating, H. T. Warnock, J. M. Kenny, W. F. Delany, R. J. Rowlette, Edward Thompson, R. C. Peacocke, J. J. O'Sullivan, D. Walshe, J. W. Olpherts, T. B. Costello, L. F. Rowan, Dudley Forde. Dr. M. R. J. Hayes, Medical Secretary, and Mr. C. H. Gick were also in attendance. Surgeon J. S. McArdle was also present by permission of the meeting.

A Finance and Executive Committee was appointed, consisting of the following:—Doctors Power, Darling, Warnock, McDonnell, White, Hennessy, Costello, Olpherts, and Rowlette.

Dr. MacNamara was unanimously elected as Chairman and Honorary Treasurer, also Dr. R. J. Johnstone, as Vice-Chairman, Dr. M. R. J. Hayes as Medical Secretary, and Mr. Gick as Assistant Secretary.

The following resolution was carried:—

"That every consultant should ask the medical man who calls him in if he be a medical adviser, and in case of doubt to confer with the Local Medical Secretary of the district, so that the consultant may exercise his option of refusing to meet such a man in consultation."

Dr. Power and the Medical Secretary were directed to draw up a statement of the existing situation, to be sent to the Local Secretaries for circulation amongst the medical men in each area, specially emphasising the urgent necessity for each member of the profession in Ireland sending in his contribution of £1 towards the expenses of the Irish Medical Committee in accordance with the resolutions of the delegates' meeting.

The election of the other committees and other matters of importance were left over owing to the lateness of the hour.

Fatal Overdose of Veronal.

At an adjourned inquest at Margate on August 26th, regarding the death of Mary Dorothy Brophy, aged 24, the daughter of a retired engineer living in London, the jury returned a verdict of death from an overdose of veronal. The evidence given at the opening of the inquiry was to the effect that Miss Brophy, after visiting Limerick, spent one day in London, and returned to Margate and died at Cliftonville on August 17th. She had been in the habit of taking aspirin tabloids for headache, and on a chair by her bedside there was found a box marked aspirin, and bearing the name of a Limerick chemist. The contents of the box were stated by Miss Brophy's medical attendant to have been veronal, and the suggestion was made that the chemist had made a mistake. The inquest had been adjourned for an analysis of the tabloids to be made, and Dr. Wilcox reported at the resumed inquest that the tabloids found by the bedside were aspirin tabloids. Mr. Liston, chemist, of Limerick, produced his prescription book, and showed that Miss Brophy, who was well known in Limerick, was supplied by him with twelve five-grain veronal tabloids in accordance with a prescription. Those tabloids were not supplied in the box produced. The Coroner, at the request of the jury, thanked Mr. Liston for travelling voluntarily from Limerick to Margate to give his evidence. The jury expressed the opinion that veronal should be scheduled under the Sale of Poisons Act.

The Departmental Committee on Alleged Excessive Claims for Sickness Benefit.

The names of the five medical practitioners placed upon the Departmental Committee appointed by Mr. Masterman to inquire into and report upon the alleged excessive claims upon and allowances by Approved Societies in England in respect of sickness benefit, mentioned in this column last week, are Mr. Adam Fulton, M.B., Miss M. H. Frances Ivens, M.B., Mr. James Pearse, M.D., M.O.H. of Trowbridge, Mr. Lauriston Elgie Shaw, M.D., F.R.C.P., and Mr. J. Smith Whitaker, M.R.C.S., Deputy Chairman, Insurance Commission.

Women's Medical College.

Lady Hardinge has received the sum of £70,866 towards the proposed Women's Medical College and Hospital at Delhi. The ruling Princes of Jaipur, Haidarabad, Kotah, Baroda, the Maharani of Hutwa, and the Jodhpur Durbar are the principal subscribers.

Outbreak of Typhoid near Rochester.

It is reported that typhoid fever has broken out at Chalk, a village near Gravesend, and since Thursday there have been twenty cases. The villagers obtain their supply of water from four ordinary wells, which are supposed to have become contaminated. The sanitary authorities have taken active measures to deal with the epidemic, and they have received assistance from the Joint Hospital Board of Rochester and Chatham. The patients are being removed to the rural isolation hospital.

NOTICES TO CORRESPONDENTS, &c.

☛ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

NATIONAL HEALTH INSURANCE COMMISSION (ENGLAND).

THE National Health Insurance Commissioners for England propose to appoint certain Medical Officers. Candidates must be registered Medical Practitioners of not less than ten years' standing, who have had experience of general practice. The salaries, pensionable, will be as follows:—£500; after three years £600; after five more years £700, and after another five years £800 per annum. Medical Officers will be required to travel and to live at headquarters approved by the Commissioners. Forms of application may be obtained from the Secretary, National Health Insurance Commission (England), Buckingham Gate, London, S.W. Letters applying for forms should be endorsed "Medical Officer" on the envelope. No application for forms will be considered if received after 22nd September, 1913.

P. R. (Bradford).—The commercial "bleaching" of flour neither increases the acidity nor the soluble extract of the flour. Experiments have shown that the process does not render flour so treated injurious either to man or to animals.

MR. F. COHEN (Shanklin).—The parasite *Nosema apis*, the cause of the "Isle of Wight" bee disease (Microsporidiosis), forms spores, and certain bees act as parasite "carriers," thereby spreading the affection. Drs. Fautham and Porter recommend going over the woodwork of infected hives with a painter's lamp before they are used for new stock.

INDECENT ADVERTISING METHODS.

M. J. T. (London, S.W.) has forwarded us a letter which his wife has received from a firm supplying accouchement sets and sanitary requisites. At the foot of the letter the following postscript is appended:—"N.B.—Notice is given us when marriages occur, but we are not always able to ascertain the home address of newly wedded parties. The Circulars, in such instances, are sent to the address from which the marriage takes place." "M. J. T." asks whether such indecent methods of advertising can be checked, and if the practice is at all common.

[Our correspondent has just cause for complaint. The practice of puffing wares of this kind is certainly objectionable, but we fear that the sending of the present letter would not be legally regarded as an offence against the Postal Acts.—ED. M. P. AND C.]

L. S. A. (Edin.).—Full particulars of the various Post-Graduate Institutions will appear in our next issue, which will be the annual Students' Number.

DR. A. G. (Somerset).)—It is possible to prepare an artificial milk from vegetables; indeed, it is said that a company is in process of formation to erect factories for the purpose of supplying this commodity which, it is claimed, contains all the elements of the best cow's milk, and can be used for the same purposes.

P. R. (Hackney).—Our correspondent is advised not to attempt excision of the growth without first trying the effects of freezing with solid carbon dioxide.

DR. LEE (Worthing).—The gentleman to whom your letter is addressed is abroad on holiday, but will return next week.

Appointments.

DROUGHT, P. J., L.R.C.P. and S.Irel., District Medical Officer of the Romford Union.

O'BRIEN, M. A., L.R.C.P. and S.Irel., Certifying Factory Surgeon for the Fermoy District, co. Cork.

O'KELLY, T., M.D.R.U.I., Certifying Factory Surgeon for the Chipping Norton District, co. Oxford.

PEYTON, THOMAS HENRY, M.A., M.D., D.P.H.(T.C.D.), Chief Tuberculosis Officer to the County Council of Cheshire.

PICKARD, MISS, M.B., B.S., Assistant to the Clinical Pathologist at the Royal Free Hospital, Gray's Inn Road, W.C. (half time).

RICHARDS, MISS, M.B., B.S., Assistant to the Clinical Pathologist at the Royal Free Hospital, Gray's Inn Road, W.C. (half time).

TEBBUTT, HAMILTON, M.B., Ch.M., D.P.H., Chief Resident Pathologist, Royal Prince Alfred Hospital, Sydney, N.S.W.

WARD, E. L., M.R.C.S., L.R.C.P., Medical Officer of the Merthyr Tydfil Union.

Vacancies.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Harleston (Norfolk), Lisbellaw (Co. Fermanagh), Skibbereen (Co. Cork), Sunderland (Durham).

Brentford Union.—Medical Superintendent of the Infirmary and Medical Officer of the Workhouse and Schools. Salary £400 per annum, with rations, attendance, apartments, etc., together with about £80 per annum extra fees. Full particulars of W. Stephens, Union Offices, Isleworth, W.

Cumberland Infirmary, Carlisle.—Resident Medical Officer. Salary at the rate of £80 and £100 per annum respectively, with board, lodging, and washing. Applications to J. G. Howitt, Secretary.

Leicester Poor-law Infirmary.—Second Resident Assistant Medical Officer. Salary £150 per annum, with rations, furnished apartments, and washing. Applications to Herbert Mansfield, Clerk to the Guardians, Poor-law Offices, Leicester.

Monmouthshire Asylum, Abergavenny.—Junior Assistant Medical Officer. Salary £250 per annum, with board, furnished apartments, washing, and attendance. Applications to the Medical Superintendent.

Queen's Hospital for Children, Hackney Road, London, E.—Resident Medical Officer. Salary £125 per annum, with board, residence, and laundry. Further particulars of T. Glenton-Kerr, Secretary.

Somerset Hospital, Capetown.—Two Assistant Medical Officers, as House Surgeon and House Physician. Salary of each £200 per annum, with rations and quarters. Full particulars of Davis and Soper, Agents of the Somerset Hospital, Capetown, 54, St. Mary Axe, London, E.C.

Cornwall County Sanatorium.—Medical Superintendent. Salary £300, with detached furnished house. Forms to be obtained of Robert Burnet, County Medical Officer of Health, County Hall, Truro.

Warrington Union.—Assistant Resident Medical Officer. Salary £150, with apartments, rations, etc. Applications to Arthur Bottomley, Clerk, Bewsey Chambers, Warrington.

Births.

COOKE.—On August 26th at The Friary, Blakeney, Norfolk, the wife of Arthur Cooke, F.R.C.S., of Cambridge, a son.

BARKER.—On August 31st at Winstowe, St. Leonards-on-Sea, to Dr. and Mrs. E. M. Barker, a daughter.

GORDON-GREEN.—On August 29th at H.M. Dockyard, Pembroke Dock, the wife of Fleet Surgeon H.W. Gordon-Green, a daughter.

GUEST.—On August 29th at 16a John Street, Adelphi, London, to Dr. and Mrs. L. Haden Guest, a son.

KAUFMANN.—On August 26th at Mannheim, Hebelstrasse 21, the wife of Dr. Victor Kaufmann (Leonie Marx), a daughter.

KENNEDY.—On August 27th at The Mount, Market Harboro', to Eileen, the wife of Major J. Crawford Kennedy, R.A.M.C., a daughter.

LOEW.—On August 27th at 281 Woodstock Road, Oxford, the wife of Dr. E. A. Loew, a daughter.

MORGAN.—On August 31st at 18 Cornwallis Gardens, Hastings, the wife of Conway Morgan, M.D., a daughter.

OGILVY.—On August 29th at Long Grove House, Epsom, the wife of David Ogilvy, M.D., a son.

STEWART.—On August 28th at 53 Wood Street, Barnet, Herts., the wife of Bernard H. Stewart, M.A., M.D. (Cantab.), a daughter.

GRUNBAUM.—On August 25th at St. Helens, Adel, to Dr. and Mrs. Grünbaum, a son.

Marriages.

KNOX—VANCE.—On August 23rd., at Rosslyn Hill Chapel, Hampstead, Robert Knox, M.D., of 7 Harley Street, London, to Alice Vance, M.B., third daughter of the Rev. G. H. Vance, B.D., of Highgate.

THWAITES—JEFFERIES.—On August 27th at Christ Church, Heaton, Bolton, Joseph, eldest son of the late Mr. and Mrs. Edward Thwaites, of "Highfield," to Leila Etheridge, only daughter of Dr. and Mrs. Horace Jefferies, of "Welsby," Bolton.

Deaths.

ALLEN.—On August 13th at Pietermaritzburg, Natal, James F. Allen, M.D., fourth son of the late William Allen, Esquire, of Liscongil, County Cork, Ireland.

ANDERSON.—On August 26th on board ship, near Suez, of typhoid fever, Tempest Anderson, M.D., D.Sc., etc., of Stonegate, York, aged 66.

CLARK.—On August 29th at 9 Trinity Crescent, Folkestone, Andrew Clark, F.R.C.S., Colonel A.M.S.T., of Cowley Grove, Uxbridge, aged 66.

HILSTON.—On August 28th in Edinburgh, Sir Duncan Hilston, K.C.B., M.D., of Chewton Lodge, Christchurch, Hampshire.

LUNT.—On August 26th at Pontypool Hospital, George Osborne Morgan Lunt, B.M., M.C.

MORRIS.—On August 31st suddenly, at Gordon Lodge, Blackheath, Clarke Kelly Morris, J.P., M.R.C.S., L.S.A., of heart failure, aged 58.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, SEPTEMBER 10, 1913. NO. 11.

NOTES AND COMMENTS.

Medical Books. ONE of the first things a student does as soon as he has chosen his medical school is to lay in a stock of books. If he be wise he will obtain some practical advice in this matter from a medical friend or a senior student who has been through the mill before he rushes into the nearest medical bookseller's and comes out the poorer by a five-pound note. Only those books that are actually needed by him at the time of entry should be purchased at first. To buy an expensive system of surgery before his third or fourth year is a needless piece of extravagance, for a good manual of anatomy, practical and theoretical, a sound text-book of chemistry, and a standard work on physiology or biology, will be all that is necessary for several months to come. By degrees he will add to his stock, and only the true bibliophile knows the pleasure of watching his medical library expand as, year by year, the volumes are added according to their owner's special needs. After qualification some of these may, doubtless, be wanted no more, and a few may become obsolete, but there is always an unwillingness to part with the old and trusted friends, with their bethumbed pages that have done such splendid service in one's student days. But the medical practitioner always remains a student, and as such he still requires books, monographs, systems and treatises, perhaps in several languages, with which he can refresh his memory in dealing with some difficult case. It is false economy to deny one's self good books.

The Value of the Medical Museum. VERY early in his career the student will make the acquaintance of the various museums attached to his medical school. At first these places are visited from a spirit of morbid curiosity, and gruesome accounts of the specimens seen are retailed around the fireside to an awe-struck family circle. A little later he finds that it is to his advantage to sit quiet upon a hard stool and study a "pickle" with the aid of his text-book, or examine the markings upon a bone in the department of normal anatomy. Meanwhile his visits to the pathological section of the museum grow less and less frequent until the end of his career, when he is "taken round" by his medical or surgical tutor and encouraged to diagnose the conditions seen in the preserved specimens which seem to look so different from what he has observed upon the *post-mortem* room table. The latter he could succeed in "spotting" for the most part, but when isolated from their surroundings and transfixed with glass rods of many colours, somehow his diagnostic powers seem to have vanished. Nevertheless, the pathological museum is an institution of real educational value, and many a man engaged in busy practice has ample opportunities for securing good specimens of tumours, malformations, calculi, or what not, which the curator of his hospital museum, or even that of the Royal College of Surgeons, may be only too glad to receive.

Hospital Appointments. THE success or otherwise of the student's career is commonly measured, not by the number of prizes and medals won at examinations, but by his holding of an appointment upon the junior resident staff of his own hospital. Has he been fortunate enough to obtain the position of House Physician or House Surgeon? Then his position is more or less secured, for although most house appointments are unpaid, the *kudos* that attaches to their holder marks him out as a man likely to "get on" to the hospital staff should he hang about doing demonstratorships, etc. In the smaller general hospitals in the Metropolis without medical schools, and also in the provincial hospitals, house surgeons and resident medical officers are paid officers, though the tenure of office of these posts seldom exceeds one year. These appointments are of priceless value to their holder, for no small responsibility attaches thereto, inasmuch as a house officer is brought into intimate relationship with the public, in the casualty and out-patients' departments, as well as in the wards. At the present time there is said to be a dearth of candidates for these posts in many quarters. In some cases this falling off of suitable men may be due to the eagerness of newly qualified men to embark upon general practice for themselves. It cannot be too strongly impressed upon the neophyte that, from the point of view of gaining invaluable experience in the treatment of all manner of diseases and injuries, it is worth his while to take up one such post for at least six months before deciding upon any future sphere of work.

The Fortunes of the Small Hospitals. THE financial pathway of the smaller voluntary charities, as a rule, is not strewn with a prodigal wealth of roses—often their story is one of perennial struggle in the face of difficulties that would be regarded as hopeless in any ordinary human endeavour. As a matter of fact, they have to depend on benevolence that is fitful, and inclined in many cases to bestow its favours upon the clamorous and insistent, rather than upon the modest and retiring. During the past generation an attempt has been made to evolve some sort of order out of the chaos of the medical charities, with the result that the bulk of the money available is now collected by certain responsible agencies or Funds scattered throughout the Kingdom. These agencies, excellent as they undoubtedly are in intention, have added grievously to the difficulties of the smaller hospitals. In most of them the responsibility of distribution goes hand in hand with that of collection. Their executive is made up almost exclusively of individuals who are interested, directly or indirectly, in the large institutions, with the inevitable result that grants to small institutions either become reduced to slender proportions or altogether disappear. The only exception, as was proved with chapter and verse in these columns some years ago, is when the chairman of a special hospital happens to have a seat on the management of a distributing fund. It has, in a word, been evident for many years that the deliberate policy of the Funds has been gradually to extinguish the small hospitals.

The Policy of the Hospital Funds.

THIS curious result was certainly not anticipated by the originators of the Funds. In one particular instance, at any rate, a great Metropolitan Fund was instituted by the then chairman of a special institution. Why should not the small hospitals be represented on the committees of the Hospital Funds in all parts of the Kingdom? The justice of such a course needs little supporting argument. The smaller institutions were the precursors of the special departments in the large general hospitals. In the special hospitals of the United Kingdom at the present moment unrivalled scientific work is being carried on day by day. It is indeed difficult to appreciate at anything like its true value the indebtedness of medical progress to specialism as carried on on present lines. Under these circumstances it will be little short of a public calamity if the arbitrary policy of the Funds be permitted seriously to damage the prospects of the special hospitals. It is difficult to believe that His Majesty King George—whose sympathies are wide, as his judgment is usually sound, in public affairs—can be fully informed as to the facts of the distribution of the great Fund over which he presides. Were he to insist on a proper representation of the small hospitals upon the executive of the King Edward Fund, a great deal of the present inequality and injustice would drop out of existence.

"Alexandra Rose Day."

NOT the least part of an abuse of the kind is that, once perpetrated, it is likely to be adopted as a precedent by succeeding distribution agencies. Such an one, indeed, has sprung up in the shape of the Queen Alexandra Fund, an exceedingly graceful and popular organisation, the object of which is to collect money for the London Hospitals. The collection is made practically in the streets, and is to a large extent derived from pennies contributed by poor and middle-class persons—that is to say, by those who find an untold amount of succour and relief from the special hospitals. Yet even this new comer excludes from the grants all but a few of the small hospitals—regardless of the unblemished reputation, the long-continued labours, or the whole-hearted philanthropy that characterises the majority of such institutions. It may be at once stated that the omission of the small hospitals is no part of Queen Alexandra's policy, but rather that of an irresponsible self-elected committee, who apparently have not thought it necessary to ascertain Her Majesty's views upon the subject of distribution. If the Fund which bears a name so honoured in the annals of British philanthropy is to secure general approbation, it must be administered by a properly appointed committee, containing amongst its members a fair proportion of representatives of the small hospitals.

Panel Dentists.

A SUBJECT of great national interest was discussed the other day at the Annual Congress of the Incorporated Dental Society—namely, the advisability of adding a dental panel to the existing machinery of the National Insurance Act. Considering the supreme importance of good dentition to health, it is somewhat surprising that dental benefits were not included from the first. Modern bacteriology has shown that decayed teeth act as channels, as well as foci, of infection, and it is at least probable that the virus of many specific diseases may obtain an entrance into the system through such portals. It is far easier to prevent than to cure, and many a case of anæmia and incipient phthisis, not to mention pronounced dyspepsia, might be remedied in the earliest stages by timely attention to the teeth. If the funds were insufficient to provide for free dentistry for panel patients at the time of the passing of the Act, a further sum might be voted by the Government for this express purpose. It is understood that the Chancellor of the Exchequer is deeply interested in the proposal, and that it has the support of a number of eminent dental surgeons throughout the country.

The Tuberculosis Officer.

A NEW field of activity has been opened up for medical men since the passing of the National Insurance Act in connection with the administration of sanatorium benefit. The demand for tuberculosis medical officers throughout the country has created a new type of medical official, for there are already large numbers of tuberculosis officers—or, more simply, "T.O.'s"—already in the field doing splendid work in the national struggle against consumption. The work is interesting and engrossing, calling forth powers of organisation and of diagnosis. In the latter respect it is of the utmost importance that candidates for these posts should have held some appointment at one or other of the large chest hospitals, for he will have the responsible duty of deciding in doubtful cases whether a patient be suffering from tuberculosis at all and what form of treatment should be prescribed. The principal duty of the T.O. is to act as medical adviser to the local Insurance Committees in connection with the working of sanatorium benefit, and also to take charge of the work of the tuberculosis dispensaries. The dispensary is really the main unit of the Departmental Committee's scheme, and may be regarded as the clearing house for all cases of tuberculosis. The work at present demands the officer's whole time.

On Reading Character.

FEW men have such unrivalled opportunities for the study of their fellow-men as the medical practitioner. If he be something of a character reader he can daily exercise the art and test the principles of Gall and Spurzheim for himself. Indeed, the would-be medical anthropomorphologist or phrenologist will instinctively take stock of his patient during an interview and mentally label him in his proper class. The physical and mental traits of the different types of character can be appraised, at any rate with an approximate degree of certainty, in the course of a few minutes' conversation by the student who has learned to interpret such signs aright. In this sense the medical man needs to cultivate those powers of observation made use of by the detective who seizes upon small, yet unfailing, indications to guide him in forming an opinion upon a case. That certain popular errors in reading faces need to be dispelled is evident after the perusal of a recent Government Bluebook on "The English Convict," which contains the results of a remarkable statistical investigation by Dr. Charles Goring, Medical Officer of Parkhurst Prison, based upon measurements of prisoners. According to these observations, there is no such thing as the criminal type of face, for in head measurement the criminal "does not differ perceptibly from Oxford or Cambridge undergraduates." Not very flattering to young University bloods! Neither does a high forehead always signify great intelligence, nor a retreating frontal region a cunning criminality. This being the case, the medical practitioner will have to be more wary in future in forming an estimate of his patient's character.

"Should the Doctor Tell?"

The echo of an old newspaper correspondence is revived once more in a story which comes from Nottingham of an inquest upon a female suicide, for in the account of the evidence thereat a medical man is alleged to have informed the deceased that she "would never be the same again" owing to the state of her heart. A witness remarked that he could not "understand a doctor saying such a thing in the presence of a patient," as he might be sure it would cause depression. It certainly requires a good deal of tact to know when to reveal the actual diagnosis to a patient, and if the latter be at all nervously inclined it is probably the wiser course not to tell him immediately that he is suffering from a mortal disease. No harm can result from a postponement of the death sentence, as it were, by the medical man, unless the patient be specially anxious to "know the worst." A guarded prognosis in the great majority of cases is the safest course to pursue, for what practitioner is there who has not experienced the surprise of having his verdict happily reversed and of seeing his patient, after having one foot in the grave, live to enjoy many years of life? Many neurotic patients and those of a worrying disposition are invariably made worse by being told that they have such and such a malady, and much diplomacy and even "hedging" will have to be legitimately resorted to to satisfy their insistent demands for information which would only do them harm. The true state of affairs can generally be confided to a relative or friend if necessary, but the patient, especially a heart case, should always be spared the shock of knowing his real condition, if that be a grave one.

Neology in Medicine.

There is no sign of any diminution in the manufacture of fresh medical terms, as a reference to any good medical dictionary will show. Medical nomenclature has always provided a source of high amusement to the general public, who delight to talk about the wonderful crackjaw names the doctors give to their diseases. To the classic scholar, however, such terms are mostly self-explanatory, and their length, though seldom attaining the linear dimensions so commonly met with in German scientific literature, is quite commensurate with the lengthy phrase which they so aptly substitute. It would be an interesting study to estimate the length of life enjoyed by a newly coined medical term, for even such scholarly inventions as those of Coleridge and Sir Thomas Browne seem born only to die. Words descriptive of surgical operations are certainly comparatively short-lived, for operative procedure changes with the growth of knowledge. It is as true now as in the time of Ben Jonson that "a man coins not a new word without some peril, and less fruit; for if it happen to be received, the praise is but moderate; if refused, the scorn is assured." What responsibility, therefore, rests upon the medical neologist, for of medical word-making (and word-taking) there is, indeed, no end. At the present rate of multiplication one hardly dare speculate as to the amount of shelving-room that will be needed for the medical dictionary of the future.

PERSONAL.

Dr. W. H. Nutt, Ch.B.Edin., has been appointed Honorary Radiographer to the Chesterfield and North Derbyshire Hospital.

Dr. F. Howard Humphris has been elected President of the Brussels Medical Graduates' Association for the ensuing year.

Dr. W. R. W. Asplen, M.B., B.S.Lond., M.R.C.S., L.R.C.P.Lond., has been appointed Deputy Coroner for Central Warwickshire.

Dr. Douglas Edward Finlay, M.B., B.S.Lond., has been appointed a Physician to the Gloucestershire Royal Infirmary and Eye Institution.

Dr. Andrew Leslie Dykes, M.D.Edin., lately of Plaistow Fever Hospital, has been appointed Assistant Medical Officer of Health for Oldham.

Mr George Finch, M.R.C.S., L.R.C.P., of West House, Southover, Lewes, formerly Assistant School Medical Officer to the East Sussex County Council, has been appointed Assistant Tuberculosis and School Medical Officer to the East Suffolk County Council.

Dr. John Evans, of Swansea, surgeon, one of the leading members of the Executive of the Swansea Liberal Association, and formerly a member of the Old Swansea School Board, who died on January 3rd last, aged 69 years, left estate of the gross value of £3,309 0s. 7d., with net personalty £546 3s. 6d.

A stained-glass window was unveiled at the ancient church of St. Martin, Ashton-upon-Mersey, on Sunday last, to the memory of Jeremiah Renshaw, surgeon, who practised in Ashton-upon-Mersey and Altrincham from 1831 to 1862. Mr. Renshaw was one of the early members of the British Medical Association, in the time of its founder, Sir Charles Hastings. The window has been erected by his son, Dr. Charles J. Renshaw.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Reginald O. Moon, M.D.Oxon, F.R.C.P.Lond., Assistant Physician Dreadnought Hospital for Women; Physician Hospital for Diseases of the Heart, London, W., etc., etc. Subject: "Functional Diseases of the Heart."*

EDUCATIONAL SUMMARY FOR 1913-14.

INTRODUCTORY REMARKS.

In a "Students' Number" it is usual to commence with a brief, informal address to those who are about to commence their studies in one of the most complex as it is the most progressive and—we are happy to believe—the most noble and humane of all professions. The necessity of a wide general culture for all who aspire to its membership is registered in the scope of the preliminary examination. For those who aspire to its highest honours it is necessary to possess a knowledge of many things outside the formal limits of the art and science of medicine, and above all to acquire an intimate acquaintance with men and manners. Happily, this does not mean that the aspirant must needs have a University training, for some of the men whose names are household words in the profession have not enjoyed that advantage, while others have started from the lower steps of the social ladder. The prizes of the profession, in fact, are open to all comers who can bring sound brains and determination of purpose to their task, assuming, of course, that they are able to obtain an adequate preliminary education and the funds necessary to meet the expenses of medical curriculum and qualification. Of late years the tendency has been to include in the preliminary examination subjects that would be of direct use to the student in his later career in the schools. It would be difficult to imagine a better training for a young man than that required in mastering the elements, say, of botany, zoology, and chemistry. At the outset of our remarks it has seemed natural to dwell upon the intellectual side of the career of medicine, for in that will be found a solace for the trials and difficulties that must be faced in that as in all other walks of life. From the monetary point of view it is open to any man of ordinary gifts and application to secure a competency, although he may have at first to go through a more or less extended period of years spent in the weary task of waiting for practice. It is well to point out that under present conditions few may hope for the prizes that are met with in general, in consulting, in special, and, in some cases, in the army, navy, and civil services.

The average medical man is content to live a plain, hard-working career, of which the material reward will be a modest competency and the higher moral assurance that his years have been well spent in the service of his fellow creatures. He may at once dismiss all dreams of fame, title and fortune, for these are given to the few. In some ways, however, his path as a private practitioner is likely to lead through more roseate pastures than those to which he has hitherto grown accustomed by long usage. Of late years the State has taken upon itself more and more responsibility as regards the health of the citizen. In this way new services have been created and old services augmented with the view of extending to the poorer classes the advantages of modern preventive and curative medical science. Such, for instance, is the school medical service and the greatly increased and partly specialised Poor-law medical service. Last, but not least, comes the much-vexed National Insurance Act, which provides a comprehensive scheme for the provision of medical attendance to the labouring classes on a scale hitherto undreamed of. In spite of the mixed feelings with which this Act has been accepted by the medical profession, it has come to stay. It may be said broadly that, although in some cases Mr. Lloyd George's Act has inflicted great hardships upon individual medical men, it has on the other hand greatly augmented the gross income previously derived by medical men from the insured classes. In future the panel appointment will count for a good deal with the medical man whose field of labour lies partially or wholly among the poor. In any case, a State appointment of the kind, however irksome and laborious, must rank immeasurably higher than the open dispensary practice with its degrading circumstances. It is indeed deplorable to find a member of a learned and honourable profession offering physic and advice for sixpence, or even threepence a consultation. In the course of time, however, we may hope that the conditions of which this kind of undesirable medical practice is the outcome may be removed, and that there will be no need for any qualified man to adopt such discreditable methods.

From the first day that he commences his medical studies the student will do well to keep steadily in view the necessity for keeping abreast of new ideas. The present age is one of thinkers, and it is filled with fresh ideas in all branches of intellectual activity with an exuberance that has never been equalled at any previous period of human history. Above all is this true in medicine. The student of a generation ago finds himself surrounded with a host of new methods, remedies and appliances, the very jargon of which demands for its interpretation the brains of a general specialist. To-day the private practitioner must have a knowledge of vaccines, of many laboratory methods of diagnosis, and of a long list of technical processes, or, at any rate, of their principles and their practical application, as, for instance, in the case of the Wassermann test for syphilis and the treatment of that malady by Ehrlich's famous "606."

In all classes of practice the need of the pathologist is everywhere more apparent. So great, indeed, has become the necessity that we were lately informed on good authority that a famous German physician had a full clinical examination made of each patient before the latter entered his consulting room. The student, bearing this in mind, will do well to pay careful attention to the acquirement of a working knowledge of the main methods of the clinical and pathological laboratory. At the same time it can hardly be too strongly impressed upon him that it is necessary to cultivate the habit of close bedside observation of his patient. It is impossible to replace by the test tube and the microscope that carefully trained faculty which has been aptly described as the "clinical sense," the presence or absence of which not infrequently determines the success or failure of the medical man in his professional career. It should be remembered that the conditions of actual practice differ widely from those met with by the student in a well-appointed hospital. In dealing with private patients the practitioner is thrown upon his own resources, and may have to meet serious casualties and emergencies with the slenderest of surgical and medical resources. An extreme instance of the kind is when a medical man is called upon to treat a foreigner *in extremis* unprovided with a stethoscope or other ordinary professional appliances, and unable to communicate directly or indirectly by word of mouth with the patient or his friends. Under such circumstances the diagnostic faculties of the medical observer are put to a crucial test. An instance that sometimes happens in private practice at home is when a medical man is called by the police to an unconscious patient. An error in the diagnosis of alcoholism or other narcotic poisoning, fractured base of skull, concussion, diabetic coma, apoplexy, and so on, may destroy the patient's chance of recovery and have a disastrous effect upon the reputation of the medical attendant. Any man who has carefully trained his clinical senses will lessen proportionately the chances of error in this admittedly difficult branch of diagnosis.

From an early period of his studies, the student will do well to devote some attention to the wider aspects of professional work, for the real business of his life begins after the days of his probation. There are many ways in which the position of the medical practitioner might be greatly improved. Nor is it going too far to say that most of them would be attainable were a proper representative body created to protect the interests of the profession. One of the early questions that the student would do well to bear in mind is the relation the General Medical Council and the Medical Corporation he has joined will have towards his future career. Will they leave him in absolute neglect from the day of his final qualification, or will they do anything to help him on in the professional struggle? For some reason or other the profession is in the unstable position allotted in sacred writ to the house divided against itself. Instead of a single-portal entrance to the profession, as in law, we have a score or more of conflicting corporations. Indeed, the spirit of rivalry, and of individual as apart from collective action, seems to be so deeply rooted as to render the outlook for future consolidation somewhat discouraging. Yet the signs of the times do not point all in one direction. The British Medical Association, in spite of various defects and errors, has shown that great things are possible to a great profession with a common object in view. The success of many other purely professional organisations, moreover, points the moral of the tale sufficiently well to show that the road to professional paradise lies through the gate of co-operative union. Lastly, there is the recent opposition to the National Insurance Bill.

Choice of a School.

Many things are concerned in the choice of a school. Tradition, family influence, proximity, means, and acquaintance with other students or members of the staff all come into play, and there are few who are not affected by them. The would-be student, however, who has the whole collegiate domain open to him and his selection unhampered by other consideration than that of merit, has the choice of nearly twenty centres in which to follow his bent. There is a natural tendency for a man to look to his immediate vicinity for the maturing of his genius, and in these days, when Universities are cropping up with bewildering frequency, most students will probably find one within fifty or sixty miles of their homes. As the medical curriculum is laid down carefully by the General Medical Council, there is not much variation in that of the individual schools, and a good all-round education can be relied on in practically every one. On the one hand, some have teachers of established ability and reputation, whilst others are seeking to obtain that enviable notoriety, and while some men may be attracted by the spirit of adventure to cast in their lot with the new and struggling, others will prefer the security of well-trodden paths. The object of this number of The Medical Press and Circular is to present impartially the claims and attractions of all schools, and if parents and their wards study its pages carefully they will, we feel sure, be convinced that there are none that have not their own special charms. The outlay on actual necessary educational expenses does not differ materially in different places, the higher cost of certain centres being chiefly due to the greater cost of living. It is obvious that in London, for instance, where rents are high, the cost of lodgings must be considerably more than in many smaller and less favourite towns, while, on the contrary, a student living in his parents' home in London will not be so much expense to them if he goes to a London Hospital as if he takes up his abode at a northern University. But, other things being equal, it is important for the average student to choose that school at which he is most likely in after years to obtain a resident post.

Choice of a Qualification.

One day, in the not very distant future, we hope, the choice of what qualification to study for will not present so great a difficulty as it does to-day. Owing to the haphazard way in which British institutions and customs grow up, there have come into being a number of rival interests, both pecuniary and scholastic, which it is difficult to break down, with the result that students are offered all sorts of qualifying diplomas, conferring on them the right to append almost every conceivable alphabetical combination to their names. It may be laid down in general terms that the shortest and least picturesque of these designations will generally be found the most serviceable, both from the expenditure of time that it will save in signing certificates, and in the greatest ease by which it will be understanded of the people. Happily, or unhappily, a qualification even of the highest order has, as a rule, but small relation to success in practice, and many practitioners of light and leading will be found to have laid the foundations of their success on a more solid basis than that of academical triumph.

Course of Study.

Although there are certain individual variations, the course of study pursued at all the medical schools is pretty much the same. One or two of the Universities are a little exacting in the number of special subjects they pile on to the crouching backs of their alumni, but in course of time it is generally found that the other centres of instruction follow their lead. Still, it is well to remember that from the moment the student pays his fee to the dean, the disposition of each moment of his time for the next five years is laid down with procrustean exactness, and that any diversion in the shape of amusement, illness, or failure in examination connotes a corresponding addition to the length of his pupilage.

Medicine, then, it should never be forgotten, is the means to an end, and that end is the amelioration of man's lot on earth, and not the aggregation of wealth. As the first it is a brilliant success; as the latter it is a sorry business. It is a career which should be chosen only after due deliberation, and by those alone who are prepared to accept whatever fate may betide them with cheerfulness and courage, secure in the faith that is begotten of high ideals and of a sense of duty manfully discharged.

THE ENGLISH UNIVERSITIES.

The English Universities, including Wales, are ten in number—viz., Oxford Cambridge, London, Manchester, Durham, Liverpool, Leeds, Sheffield, Birmingham, Bristol, and the University of Wales. The choice of a University is usually determined by social, geographical, and financial considerations. Students whose parents are able and willing to incur the necessary expense will do well to select one of the ancient Universities, since their degrees confer upon their holders a status not accorded by the public to the degrees of more modern institutions. To those less favoured by fortune, but blessed with energy and a fair share of intelligence, the London University offers ample scope, and its degrees are recognised as the outward and visible sign of high professional attainments. A capable and industrious student, however, may equally well lay the foundations of success in one of the newer provincial Universities.

UNIVERSITY OF OXFORD.

There are two degrees in Medicine, B.M. and D.M., two in Surgery, B.Ch. and M.Ch., and two diplomas, Public Health and Ophthalmology.

Graduates in Arts (B.A. or M.A.) are alone eligible, except for the Diploma Examinations. To obtain the B.M. and B.Ch. the following examinations must be passed:—1. Preliminary Mechanics and Physics, Chemistry, Animal Morphology, and Botany. 2. Professional. *(a)* First Examination: (1) Organic Chemistry, (2) Human Anatomy. *(b)* Second Examination: Subjects—(1) Medicine, Surgery, Midwifery, (2) Pathology, (3) Forensic Medicine with Hygiene and (4) Materia Medica with Pharmacy.

The First Examination for B.M. and B.Ch. may be passed as soon as the Preliminary Scientific Examinations have been completed. The subjects may be presented separately or in any combination or in any order, provided Anatomy and Physiology be passed together.

The Second Examination may be passed after the completion of the first, but Pathology and Hygiene may be taken before or with the remaining subjects. Before admission candidates must present certificates of attendance on a laboratory course in Practical Pathology and Bacteriology and of having acted post-mortem clerk for three months, surgical dresser for six months, and clinical clerk for six months. Also they must produce certificates of instruction in Infectious and Mental Diseases, and of attendance on Labours, and of proficiency in the practice of Vaccination and the administration of Anæsthetics. Also in respect of the First Examination candidates must present certificates showing that they have dissected the whole body once and have attended courses of laboratory instruction in Practical Histology and Practical Physiology.

The degree of D.M. is granted to Bachelors of Medicine of the University provided they have entered their thirty-ninth term and have composed on some medical subject a dissertation which is approved by the professors in the Faculty of Medicine and examiners whose subject is dealt with. A book published within two years of the candidate's application for the degree may be substituted for a dissertation. The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-seventh term.

Diploma in Ophthalmology.—There is an examination once in each year in the Theory and Practice of Ophthalmology for the purpose of granting certificates of proficiency therein, styled Diplomas in Ophthalmology. The examination is under the supervision of the Board of the Faculty of Medicine, which has power to make regulations as to the subjects of the examination, the time at which the examination is held, and the conditions of admission. No candidate is admitted to the examination for the diploma who has not pursued at Oxford a course of study in Ophthalmology approved by the Board of the Faculty of Medicine, and extended over a period of at least two months.

Travelling Fellowship, Scholarships, and Prizes.—A Radcliffe Travelling Fellowship is awarded annually after an examination held in February. It is tenable for three years and is of the annual value of £200. Application should be made to the Radcliffe Examiners, Radcliffe Library, University Museum. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing and who have passed all the Exams. for the degree of B.M. or B.A. for an original research in some Biological subject, including Physiology or Pathology. The Radcliffe Prize, founded by University College (1907), is of the value of £50 and is awarded biennially for research in some branch of medical science. The Theodore Williams Scholarships of the value of £50 each are awarded annually in the subjects of Anatomy, Physiology and Pathology.

Detailed information may be obtained from the University Calendar.

UNIVERSITY OF CAMBRIDGE.

At the University of Cambridge five years of medical study are required for the M.B. and B.C. degrees. The candidate must have resided nine terms (three years) in the University, and have passed the "previous" examination in classics and mathematics. There are three examinations: The first in (1) chemistry, (2) physics, and (3) biology; the second in (1) human anatomy and physiology, and (2) elementary pharmacology including pharmaceutical chemistry and the elements of general pathology; and the third in (1) surgery and midwifery, and (2) principles and practice of physics, pathology and pharmacology. The first examination is divided into three parts, and the second and third examinations each into two parts, which can be taken separately. Subsequently to the third examination an Act has to be kept which consists in reading an original thesis, followed by an oral examination on the subject of the thesis. As the subjects for the examination for the degree in surgery are included in the third examination for the M.B. degree, candidates are admitted to the degree of Bachelor of Surgery on passing the third examination for Bachelor of Medicine.

The M.D. degree may be taken three years after the M.B. An 'Act must be kept, including the presentation of an original thesis, with oral examinations and an essay to be written extempore. There is also the degree of Master of Surgery, for which the candidate, having already passed for B.C., or being M.A. has otherwise qualified in surgery, has to pursue extra study in surgery, and has a special examination or submits original contributions of merit to the science or art of surgery. The yearly expenditure of a student who keeps his terms by a residence in a college is from £150 to £200 a year. This, however, may include all payments to the University and the College—all fees as well as clothes, pocket money, travelling expenses, &c. Non-collegiate students have to pay the University fees only, which are not large. They lodge and board in the town; their expenses, therefore, are largely in their own hands. Various studentships, scholarships and prizes are open to medical students.

The University grants a diploma in public health without the necessity of residence, the examination being in so much of State Medicine as is comprised in the functions of officers of health, and subject to the latest requirements of the General Medical Council. These examinations are held in Cambridge the first week in April and October. Candidates, whose names must be on the "Medical Register" of the United Kingdom, and need not be members of the University, should send in their applications to the Secretary of the State Medicine Syndicate a fortnight in advance. Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a University Diploma testifying to his competent knowledge of the subjects comprised in the duties of a medical officer of health.

There is also a special examination in Tropical Medicine and Hygiene, held annually twice—in January and in August. It is open to qualified practitioners under certain conditions as to previous study and experience. Successful candidates receive a University Diploma.

An abstract of all Regulations may be obtained upon sending a stamped directed envelope to the Assistant Registrary, Cambridge. Full information is contained in the University Calendar.

UNIVERSITY OF LONDON.

The University of London became in 1900 a teaching as well as an examining body. The medical degrees awarded are those of M.D., M.S., and M.B., B.S., the two latter being now given together as a graduating degree. The medical degrees are granted to both internal and external students, the former being students of the constituent schools and colleges of the University.

The Matriculation Examination.—Students, before being admitted to the University, must either (1) have passed the Matriculation or the School Examination, or (2) have been exempted therefrom under Statute 116 of the University which recognises certain other examinations in its lieu. The examinations for matriculation take place three times in each year—in September, in January, and in June. Fee £2. If he withdraws before the last day of entry it will be returned to him. If he fails to present himself he will be allowed to enter for a subsequent Matriculation, within eight months, on payment of £1. If he retires after the commencement of the examination, or fails to pass it, the full fee of £2 is payable on every re-entry.

Provincial Examinations for Matriculation.—These are appointed by the Senate upon the application of any city, institution, or college desiring to be named as a local centre, and are carried on simultaneously with the examinations in London. Candidates must give notice upon their forms of entry to the Principal of the University, who will then make all necessary arrangements. Besides the University fee, a fee, usually varying from £1 to £3, is charged by the local authorities, and must be paid at the local centre immediately before the several examinations.

Faculty of Medicine.—The Faculty of Medicine grants the joint degrees of M.B., B.S. (Bachelor of Medicine and Surgery), and the higher separate degrees of M.D. (Doctor of Medicine) and M.S. (Master of Surgery). The curriculum for the medical degrees covers five and a half years, except in the case of students who have passed the Preliminary Scientific Examination or the First Examination for Medical Degrees, before July, 1910, and the examinations formerly known as the Preliminary Scientific, the Intermediate, and the Final Examination in Medicine are now respectively entitled the First, Second, and Third Examinations for Medical Degrees.

The First Examination for Medical Degrees (Inorganic Chemistry, Physics, and General Biology) takes place twice in each year, commencing on the Monday following December 10th, and on the second Monday in July. The fee is £5 for each entry to the whole examination, provided that all the subjects are taken at one time. When less than the whole examination is taken at one time, it is £2 for each subject.

The Second Examination for Medical Degrees (Part I.): Organic Chemistry.—This examination takes place twice in each year. No candidate will be admitted to this examination within six months of having passed the First Examination. The fee is £2 for the first and every subsequent entry. The examination will consist of a paper and practical work, and may include oral questions in Organic Chemistry, which is "to be treated in an elementary manner, and with special regard to its applications in physiology, pharmacology, and pathology."

The Second Examination for Medical Degrees (Part II.) takes place twice in every year, commencing in 1914 on the second Monday in March, and on the first Monday in July. The subjects of the examination are Human Anatomy and Embryology, Physiology, and Pharmacology, including Pharmacy and Materia Medica. No candidate shall be admitted to the examination unless he has passed the First Examination for Medical Degrees at least 18 months previously, and has passed Part I. of the Second Examination for Medical Degrees. The fee for each entry to the whole examination is £8. For re-examination in one subject it is £4.

M.B., B.S. Examination.—The M.B., B.S. examination takes place twice in each year, commencing on the fourth Monday in October and on the first Monday in May. Candidates will be examined in Medicine (including Therapeutics and Mental Diseases), Pathology, Forensic Medicine and Hygiene, Surgery, Midwifery, and Diseases of Women. The subjects may be divided into two groups, namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Midwifery, and Diseases of Women. These groups may be taken either separately or together. The fee is £10 for each entry to the whole examination, and £5 for examination or re-examination in either group. There will be no separate examination held for Honours, but the list of candidates who have passed will be published in two parts, namely, an Honours list and a Pass list.
